LATION OF BODY TEMPERATURE IN HEALTH AND DISEASE*

Sir George Pickering
M.A., M.D Cantab, F.R.C P, Hon F A.C.P
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD

perhaps appropriate that, on the second day that y to preparing this lecture, I was decanted from lane at 8 A M in Labrador at a temperature of at 9 P M in Trinidad at a temperature of 90°F personal experience I was forcibly reminded of remarkable of scientific prophecies "La fixite du térieur est la condition de la vie libre"

entific generalisations can have proved so ng It occurs in *Leçons sur les phenomenes de la* ues given by Claude Bernard at the College of vo years before he died and published post- in 1878 Bernard had come gradually to his the constancy of the internal environment and tance to the organism In his well-known work mental medicine published in 1865,[1] he discussed ancy of the *milieu intérieur* and listed these emical components water content, temperature, gen, nitrogen, and CO_2), pressure, and chemical ion

ntext of the quotation from the 1878 work is as Bernard divided all life into three forms (1) "la manifestee", (2) "la vie oscillante, vie a manivariables et dependantes du milieu exterieur", "la vie constante, vie à manifestations libres et antes du milieu exterieur" Latent life is ed by seeds which lie dormant for long periods nder suitable conditions of temperature and they germinate, and in the animal world by nd eels, which may also remain dormant for long n ice, becoming active again when the ice thaws g life is exemplified by nearly all plants (partion-tropical plants), whose activity is dependent n, and by all cold-blooded animals Only those which are warm-blooded are independent of their urroundings They exemplify the third and orm of life The perpetual changes of cosmic ent do not penetrate into the animal, it is free pendent. Then Bernard goes on "La fixite du nterieur est la condition de la vie libre, ante"

is leaves us in no doubt as to the biological ce of the regulation of body temperature In this propose to discuss how this is achieved in a nan, and in the next how the mechanism is rough, or disturbed, in disease I shall concene on the nature of the regulating mechanism and e balance-sheet of heat production and heat loss, is adequately covered in contemporary and recent Finally in this lecture, to get perspective, I shall briefly the main features of the mechanisms another physical quantity, arterial pressure, mical quantity, blood-glucose

What are the Parts of the Body whose Temperature is Regulated?

It is an old observation, antedating accurate measurement, that the temperature of the extremities varies much with that of the environment The idea of constancy of internal temperature arose from measurements of temperature in the mouth, the axilla, the groin, the vagina, and the rectum More detailed exploration was undertaken by (among others) Claude Bernard, who confirmed that the venous blood leaving the limbs was cooler than the arterial, and that this difference was greater the lower the environmental temperature He also showed that blood in the inferior vena cava above the hepatic veins was warmer than that in the arteries, and that blood in the right heart was about 0 2°C higher than in the left, and thus in the aorta Thus the liver contributes materially to heat production and the skin and limbs to heat loss More recently Eichna et al (1951) have repeated these measurements in man and found the following deviations from rectal temperature

Pulmonary artery	−0 26°C
Right ventricle	−0 23°C
Inferior vena cava	−0 26°C
Hepatic veins deep in the liver	−0 03°C

In man, temperatures taken simultaneously from mouth, axilla, and rectum seldom differ from one another by more than 1°C, usually by less Of these the rectal temperature tends systematically to be the highest, and, because of the greater possibilities for heat loss from the other sites, it has in the past been regarded as the best index to arterial blood temperature Recent observations show, however, that its behaviour may be misleading in three ways

1 When the blood is quickly heated or cooled, mouth temperature reflects these changes quickly and in some circumstances nearly quantitatively, while rectal temperature may remain unchanged (Gerbrandy et al 1954) It follows that, if one is interested in rapid change in arterial blood temperature, the rectum is a bad place from which to estimate it As we shall see, ignorance of this fact led me astray many years ago

2 Comparison of aortic and rectal temperatures in people who have had grafting operations on the aorta shows that under ordinary environmental conditions rectal temperature tends to be about 0 3°C higher than aortic temperature (Cooper and Kenyon 1957)

3 The relatively high temperature of the rectum suggests that it may be a source of heat production The most likely cause is bacterial metabolism in fæces, but oddly enough this has never been investigated

So far as our present purpose is concerned, the conclusion of this section seems to be that the temperature whose constancy is being maintained is that of the deeper regions of the trunk and head I shall refer to this as the central body temperature This conclusion is of considerable relevance to the nature of the thermotaxic mechanism, as I hope later to show

How Accurate is Temperature Control?

Fig 1 is taken from the late Sir Charles Martin's Croonian lectures delivered twenty-seven years ago (Martin 1930) It shows the body temperatures of five species of animal after they had been exposed for two hours to temperatures from 5°C to 35°C At one extreme is the lizard, a cold-blooded animal whose temperature closely reflects that of its surroundings At the other is the cat, whose temperature is nearly independent of its

oonian lectures for 1957, delivered on May 14 and 16 the Royal College of Physicians of London

y in the Royal Society of Medicine library is inscribed ghtingale", and the notes in the same hand at the end that she had read it

A

environment The primitive mammals—the egg-laying echidna and ornithorhynchus, and the pouched opossum—occupy intermediate positions In man the mean rectal temperature has been stated to be 98 2°F (36 8° C) with a variation over the course of a day from a minimum of 97°F (36 1°C) at about 3 A M to a maximum of 99 3°F (37 4°C) at about 5 P M, giving a daily variation of 2 3°F (1 3°C) (Pembrey 1905)

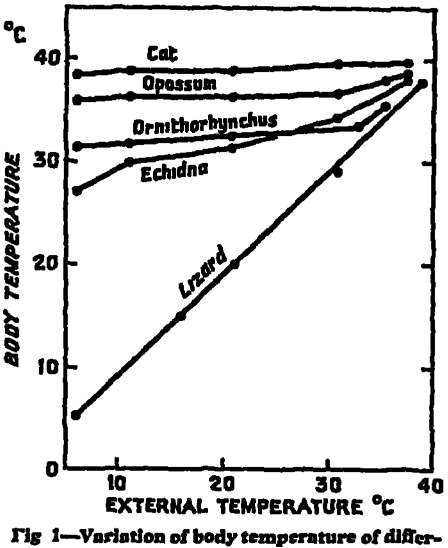

Fig 1—Variation of body temperature of different species of animals after two hours in environmental temperatures of from 5°C to 35 C (Martin 1930)

Ivy (1944) measured the mouth temperatures of 276 medical students seated in class in Chicago between 8 and 9 A M The mean was 98 1°F 68% were between 97 7° and 98 5°F, 95% between 97 3° and 98 9°F In statistical terms the mean is thus 98 1±0 4°F

These limits of variation are relatively narrow, whether we look at the variations in an individual or between individuals Indeed, Pearl (1940) concluded that the coefficient of variation of body temperature is one of the smallest for which quantitative human data are available Evidently the homœostatic mechanism concerned with temperature regulation is notable for its efficiency)

What is the Function of Temperature Control?

This was, as we have seen, discussed by Bernard Temperature control made the organism independent of its external environment Without it, the animal would be relatively, or nearly completely, inactive at low temperatures The rate of a chemical reaction is in general proportional to the absolute temperature As Sir Joseph Barcroft (1934) showed, certain reactions in the body—for example, the union of oxygen and hæmoglobin—obey Arrhenius' law, but several enzyme systems, and such functions as heart-rate and cilia-rate in cold-blooded animals, depart materially from it, the rate of increase being less than would be expected from Arrhenius' law at temperatures approaching 37–40°C

Not all warm-blooded animals are adjusted to the same temperature as man Most birds are higher, having normally a rectal temperature of about 42°C (Lefevre 1911) Among mammals the dog and rabbit normally have a temperature of 39–40°C

I am not familiar with any naturally occurring circumstances in which a temperature lower than 37°C confers an advantage on man, though modern surgery may profit Higher temperatures occur in fever, where their usefulness still remains to be demonstrated Athletes commonly warm up before a race Whether their accession of speed is due to rise of central temperature or to the effect of raised muscle temperature on its properties and performance I do not know, but the latter seems the probable

As Barcroft pointed out, one of the chief ills of high or low body temperature is *manifested by the* for consciousness tends to become clouded and later

Balance of Heat Production and Heat Loss

The temperature of the body, taken as a whole, determined by the balance between heat production heat loss Heat production consists of what one regard as obligatory and adjustable components obligatory component comprises the heat production muscle, liver, heart, and other organs carrying out th ordinary functions, whether the organism be at rest or full activity This part of heat production is not a of the device that regulates body temperature, in f it is the function of the device so to *adjust the oth* mechanisms that this component of heat production allowed for The adjustable component of heat produc tion, that which is a part of the mechanism regulating b temperature, is represented by shivering—i e, involunta contractions of voluntary muscle mediated through t motor nerves, and brought into play as a reser mechanism to maintain or raise body temperature

Heat loss is of course intimately dependent on enviro mental conditions, and, since in this age of technolog warfare the range of conditions to which man is expo *has been greatly widened, much research is being dev* to it If we ignore the changes due to intake of food drink, which are ordinarily small, the chief modes of he loss are (1) from the respiratory tract, by warming inspire air and by evaporation, and (2) from the skin, by radiatio conduction, and convection, by insensible water loss, a by sweating The dependence of all of these on th environment has been mentioned Man himself ca control the blood-flow through the skin and thus heat lo from it by radiation, conduction, and convection, and h can control sweating These are the essential com ponents, so far as heat loss is concerned, of the heat regulating mechanism

Birds and furred animals also use their coats to regula heat loss, some having different fur and feathers in winte and summer, and all being able to vary the thickness o the layer of air trapped by the coat to suit environmenta circumstances Dogs and certain other animals increas their heat loss largely by panting, the tongue and th respiratory tract being the surface Finally, man ha adopted clothing However, not all of us have been s enterprising Here is an extract from the diary of Charle Darwin for Feb 25, 1834, when H M S *Beagle* wa visiting Tierra del Fuego

> "Whilst going on shore, we pulled *alongside a canoe* w 6 Fuegians I never saw more miserable creatures, stunted i their growth, their hideous faces bedaubed with *white* pa & quite naked One full aged woman absolutely so, the rain spray were dripping from her body *Their red skins* filth greasy, their hair entangled, their voices discordant, the gesticulation violent & without any dignity Viewing such men, one can hardly make oneself believe that they are fellow *creatures placed in the same world* "

Twentieth-century civilisation has reached its fines flower in the American way of life Bertrand Russell ha pointed out that, whereas the older Western civilisation believe that man's function is to adapt himself to h environment, the modern American believes that it man's function to adapt his environment to suit himself Central heating, air-conditioning, and the automobile ıtrive to expose the heat-regulating mechanism of the ıdern American to less strain than perhaps mankind ; known through the ages To the "fixité du milieu ıerieur," modern man is adding the "fixité du milieu térieur"

To summarise, the effector part of the thermotaxic :chanism in man has two parts Heat production can increased by shivering Heat loss can be varied by rying the blood-flow through the skin, and increased by eating Variations in skin blood-flow provide the finer justments of temperature, shivering is called in by tremes of cold, and sweating by extremes of heat All ese effector mechanisms are under nervous control—ivering through the motor nerves, skin blood-flow and eating through sympathetic fibres In other warm-ooded animals panting is added as a defence against heat, ıd piloerection against cold These mechanisms are so under the control of the nervous system

Reflex and Central Control

Now we come to that aspect of the subject wherein has in my own chief interest How is the effector side tivated? Whence, in other words, comes the informa-on that leads to the opening and shutting of the arterio-nous anastomoses of the fingers, to the secretion of eat, to the erection of the hairs, and to shivering? In e past it has been usual to distinguish between reflex d central control Now, the concept of a reflex is quite ear I cannot do better than quote the master himself, r Charles Sherrington (1947)

> "The conception of a reflex therefore embraces that of at ast three separable structures—an *effector* organ—e g , gland lls or muscle cells, a conducting nervous path or *conductor* ading to that organ, and an initiating organ or *receptor* whence e reaction starts The conductor consists, in the reactions hich we have to study, of at least two nerve-cells—one con-cted with the receptor, the other with the effector For our rpose the receptor is best included as a part of the nervous stem, and so it is convenient to speak of the whole chain of ructures—receptor, conductor, and effector—as a *reflex-arc* '-A simple reflex is probably a purely abstract conception cause all parts of the nervous system are connected together d no part of it is probably ever capable of reaction without fecting and being affected by various other parts, and it is a stem certainly never absolutely at rest"

To most people central control implies the activity of a entre The idea of a centre is, compared with the idea f a reflex, much less precise It developed, I suppose, rgely to explain respiration Here was a rhythmic scharge of the central nervous system which ceased hen the brain stem was severed in the region of the ourth ventricle This was most easily explained by the resence in that region of a "centre"—i e , a group of erve-cells endowed with autonomous rhythm which ould, however, be modified by sensory reflexes and by hanging the content of carbon dioxide and oxygen in the spired air and thus in the arterial blood It proved onvenient to invent other centres—the vasomotor centre, he cardioaccelerator centre, the cardioinhibitory centre, nd the temperature centre—according to whether func-ion was lost abruptly by ablation of a specific part of the ervous system, or the appropriate activity evoked by imulating it Perhaps this was a feature of the anthropomorphic age of biological science At any rate it always eemed to me that what were called the lower centres of the brain were occupied by a lot of little men each with a quite specific job to do Many of these centres have now passed into the limbo of discarded ideas—e g , the diabetic centre of Claude Bernard, the vomiting centre, and the cardioaccelerator and cardioinhibitory centres The phenomena to which their conception was due can be explained either because the mechanisms concerned involve tracts with a finite and specific cephalad extension or else because of the location of a specific motor nucleus Nevertheless the respiratory centre remains, though somewhat shorn of its former powers It was believed to be autonomous, now it is believed that it is actuated by the hydrogen-ion concentration of certain cells of the medulla It was believed to be sensitive to arterial oxygen tension, now sensitivity to oxygen is known to be largely localised in the carotid and aortic bodies, whose receptors influence the respiration reflexly

Those who use the term " temperature centre " usually imply that it is sensitive to changes in temperature, and that in this quality, and the homœostatic effects so evoked, lies its peculiarity Functionally it is therefore rather a receptor than a centre, and because I have long thought that the concept of centres was not only imprecise but misleading I intend to use the term " central receptor " and not the term " centre " to describe that central structure or structures that respond to temperature with the appropriate homœostatic effects

Control of Vasomotor Tone in the Skin

Such, though some of the detail is new, was the background against which I saw the problem when I was first introduced to it It was my second year working with Sir Thomas Lewis Lewis had the idea that heating the body might produce a vasodilatation in the limbs, accessible to measurement by skin temperature, which might demonstrate the presence and extent of organic vascular disease We built a chamber that would enclose the trunk and in which the air could be heated by electric-light bulbs We showed that heating the trunk did in fact produce vasodilatation in the limbs , that this vasodilatation began first, and was most intense, in those parts of the hand that contained arteriovenous anastomoses , and that this vasodilatation was effected through the sympathetic nerves We found that the rate of rise and the final temperatures reached were less in patients with organic vascular disease We also obtained evidence that suggested to us the presence of vasodilator nerves, using an extremely sensitive preparation—namely, the patient with Raynaud's disease Subsequently I myself (Pickering 1936), Arnott and MacFie (1948), and Gaskell (1956) have observed that blood-flows through the hand and fingers are not significantly different in normal subjects when the body is heated, with or without previous anæsthetisation of nerves This has been interpreted to mean that the conclusions Lewis and I drew were wrong I prefer to think that it is a quantitative question, and that vasomotor nerves to the hand are quantitatively of little significance As Grant and Holling (1938) showed conclusively, they are much more important in the skin of the forearm

In view of the long controversy concerning vasodilator nerves to the hand, I think I should make my position quite clear It seems unlikely that the patient with Raynaud's disease is peculiar in her quota of vasodilator and vasoconstrictor fibres Rather is it likely that the obliterative lesions of the palmar arch and digital arteries —the basis of severe Raynaud's disease—make vasodilatation difficult in the cold hand and thus reveal that additional vascular dilatation that can be provided by stimulation of vasodilator nerves In the normal hand, where the digital arteries are patent, the vasodilatation produced by release of vasoconstrictor tone is so nearly maximal that any extra provided by vasodilator nerves cannot be detected Hess and I (1933) showed that, as measured by skin temperature, vasodilatation begins later in the foot than in the hand, and we provided evidence that this is due to incomplete release of vasoconstrictor tone in the foot, an explanation that harmonises well with the greater therapeutic effect of sympathectomy in the lower than the upper extremity

Interesting though this all was, I must confess that I was much more interested in how heating the trunk produced vasodilatation There were clearly two possibilities—namely, a reflex from the heated skin, or activation of some central structure by the hot blood returning from it Now, I had spent the year before working with Lewis on the effects of occluding the limb circulation on the pain of muscular exercise, and on nerve conduction I should have been an inept pupil if I had not realised that here lay a method that would answer the question Accordingly, when Lewis was on holiday, I set to work to see whether heating the arm whose circulation was arrested would or would not produce vasodilatation in the other

The difficulty was to get conditions right, for anyone who has worked with skin-temperature knows that conditions are broadly of three kinds (1) when environmental temperature is so high that the extremities are persistently vasodilated, (2) when the environmental temperature is so low that the extremities are persistently vasoconstricted, and (3) an intermediate zone in which finger temperature is extremely labile and the relationship between stimulus and response hard to establish

I used a cool room and subjects in whom the finger temperature had been raised to 34°C by heating in the hot box After the fingers had come out of the box, their temperature fell, and, when it was about 27°C, the other arm was immersed at 44°C with and without the circulation arrested With circulatory arrest, the skin temperature of the other hand continued to fall, until the circulation was released some minutes after release of the circulation a vasodilatation similar to that produced by the hot box ensued The method was, however, an unsatisfactory one,[2] since the time at which skin temperature rises when vasomotor tone is relaxed is greatly affected by local temperature, variations in skin temperature do not therefore accurately reflect the finer variations in vasomotor tone I therefore changed to Stewart's calorimeter, in which the heat eliminati from a hand or foot is measured, using water at 30°C—a te perature at which the hand vessels are neither unduly co stricted nor dilated This method is very robust and reliab but it is rather slow and does not detect rapid and transi effects

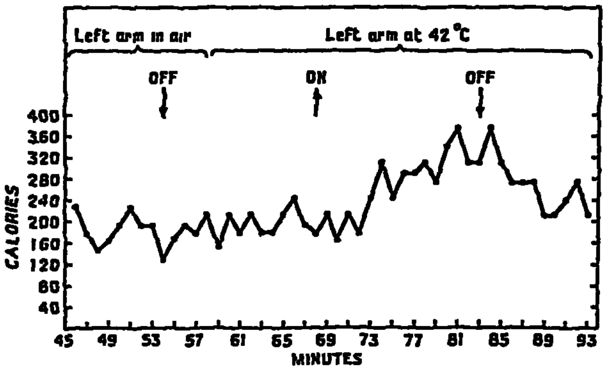

Fig 2—Elimination of heat from right hand Left arm was wrapped in cotton-wool till 59th min., when it was immersed in stirred water at 42 C. *Off* circulation to left arm arrested *On* circulation to left arm released Room temperature 21 5 C (Pickering *Heart*, 1932)

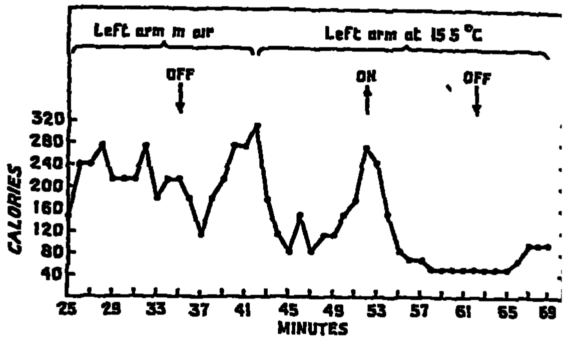

Fig 3—Elimination of heat from right hand Left arm was first air and its circulation arrested at 35th min (*Off*) It was immer in water at 15 5°C at 42nd min and its circulation released at 52 min. (*On*) (Pickering, *Heart*, 1932)

I found that, when one arm is immersed at 37°C, arresting t circulation to it induced no change in blood-flow in the oth hand, if the arm with arrested blood-flow was now immers in stirred water at 43°C, a transient vasoconstriction, but vasodilatation, occurred, when the circulation to the hot ar was released, nothing happened for a few minutes, and then vigorous dilatation began and persisted during the immersi (fig 2) Clearly the vasodilatation following the immersion an arm in hot water was not a reflex from thermal receptors the skin It arose in some way from the effect of h blood returning from the limb and acting on a more cent receptor

Cold provided a conspicuous contrast (fig 3) When t occluded limb was immersed in cold water, a vigorous vas constriction began in the opposite hand, but, as the lim remained immersed, the sensation of cold diminished, presum ably as the thermal receptors became adapted to the stimuli and coincidentally the vasoconstriction diminished If now th circulation was released, after a minute or two the vas constriction began again and this time persisted Cold clear differs from heat in that it produces a powerful vasomoto response reflexly from the receptors of the skin, it resembl heat in that a further vasomotor response is produced by co blood leaving the limb and acting on a central structur Similar phenomena were observed when the leg was immers in hot or cold water, or when heat elimination was measur from the foot during immersion of the hand

The phenomena which I had observed were not unli those observed before, but the procedure of circulator arrest enabled analysis to be made of the nature and si of the receptors initiating the reflexes

Vasoconstriction in one hand in response to immersing th other was first observed by Edwards, wrongly suppo to be confined to the symmetrical limb by Tholozan and Brow Séquard (1858), and correctly demonstrated to be a reflex b François-Franck (1876), the latent period being three second François-Franck also found that the reflex exhibited fatigue o repetition Stewart (1912), using his calorimeter, showed tha immersion of one arm in cold or hot water produced in th other hand a fall or a rise respectively in heat elimination, th former quickly, the latter only after a delay Although wi Laffer (1913) he obtained responses from the insensitive limb a patient with peripheral neuritis, he never questioned the re nature of the response Nor did Winkler (1902), who fo that, in rabbits with the spinal-cord transected, immersion o the insensitive hindquarters in hot water produced flushing o the ears only after a long delay, which he attributed to h time taken to warm the skin of the thermosensitive forequarte n view of Winkler's arguments, and doubt as to what d of thermal gradient would stimulate the thermal eptors in skin, it seemed desirable to see whether ular responses were obtainable from parts of the body irely devoid of thermoreceptors Such, as Hertz (1911) owed, is the stomach Introducing into the stomach, ough a tube, 400 ml of water at 20°C or 800 ml at °C led to the gradual onset respectively of a vasocon- iction and a vasodilatation in the hand, each lasting -30 minutes Water so introduced at 37°C and the culation of either cold or hot water through a tube rled up in the œsophagus were without effect

---

[2] And I never published these observations on skin temperature because I never regarded them as being so conclusive as those with Stewart's calorimeter

Although, at the time when these experiments were ne, the idea of a temperature centre sensitive to changes blood temperature was being entertained, no real idence had been adduced for it, and cutaneous vaso- otor tone was widely believed to be controlled by lexes from the skin The new points arising from r experiments were (1) direct evidence for control of taneous tone by a central structure responding to anges in, presumably, blood temperature , and (2) the ggestion that this structure might be extremely sensi- e To see how sensitive it was, I measured rectal mperature, and this is where I went astray, because I und that the greatest change induced during a 10-minute riod of arm immersion was 0 1°C, and that, though I as using apparatus capable of detecting 0 01°C change, change in rectal temperature had occurred when the scular effect began) To check this I also measured the at gained or lost by the body to the hot or cold water which a hand was immersed at the instant the vascular sponse began in the other arm , about 2 6 kg cal had en gained or 1 3 kg cal lost by the body If this heat in or loss was distributed uniformly over the body, it emed that the sensitivity of the central structure would e of the order of 0 025–0 050°C

This estimate has subsequently been corrected by Snell d his colleagues, who found that, whereas similar nounts of heat had to be transferred in their experiments produce vasodilatation or vasoconstriction (Snell 1954), e change in mouth temperature was so large that it had be assumed that some structures in the body would ave their temperatures changed to the same extent as if he heat transfer were confined to the circulating blood- olume (Gerbrandy et al 1954) The sensitivity of the entral receptor is thus more probably about 0 2°C

I made one further set of experiments to test the idea hat a central receptor or receptors were concerned in ody-temperature control

It seemed to me that, if heat could be provided from within he body, no question of skin receptors would arise Accord- ngly I measured heat elimination from one hand while the ubject exercised on a stationary bicycle, rectal temperature eing measured thermoelectrically A typical result is illus- rated in fig 4, which shows the effects of three periods of xercise In each the onset of exercise is accompanied by vaso- onstriction in the hand In the first two periods, which are hort, vasoconstriction persists during exercise and is followed y vasodilatation In the third period, in which the work is ager and harder, vasodilatation begins during exercise and ersists after it

The vasoconstriction which marks the beginning of exercise 1 not been described in the hand but had been in the gut nd spleen by Sir Joseph Barcroft and his colleagues, and is in onformity with the other known phenomena occurring during is period The vasodilatation occurring either after exercise during its later stages is clearly compatible with the effects a rise of blood temperature Here I ran into difficulties

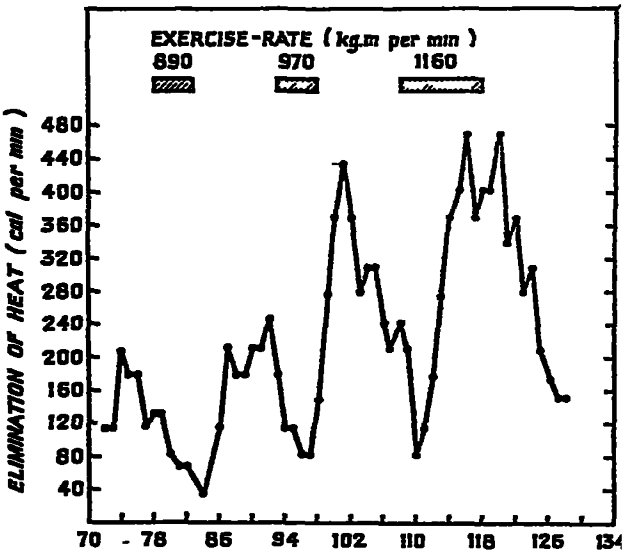

Fig 4—Elimination of heat from right hand during three periods of work on bicycle ergometer

I measured rectal temperature and got very unsatisfactory results, which I subsequently found were due to the body becoming electrically charged during exercise Before I could overcome this difficulty, my attention became diverted to the histamine headache and has since been fully occupied with other things

It is unfortunately impossible to calculate the heat gained or lost by the body during exercise of this kind, because the resting leg muscles are not at 37 C but at a lower temperature, and so an unknown fraction of heat production must go in internal redistribution of heat

Although these experiments did not enable a calculation to be made of the sensitivity of the central receptor, they were in conformity with its existence and behaviour suggested previously

I think I should apologise for having spent so long reliving an intellectual episode now more than a quarter of a century old Two reasons have impelled me to do so First, I am one of those who regard scientific research as an intellectual adventure that can provide the greatest excitement I know These were the first series of experiments in which the idea, the plan, and the execution were exclusively mine, and they have had that rather special place in my heart that a mother reserves for her firstborn Secondly these experiments and those subsequently made by Snell (1954) are the only ones which give any idea of the sensitivity of the central structure regulating vasomotor tone in man, and they indicate that it is very sensitive For this reason I have always wondered whether this structure may not be a specialised receptor[3] whence may pass impulses whose frequency determines the activity of the central nervous mechanisms governing heat production and heat loss In other words, there may be a central thermal receptor analogous to the baroreceptors of the carotid sinuses and aortic arch and to the osmoreceptors postulated by Verney

---

[3] Most receptors are in fact nervous It may be that the temperature receptors are nerve-cells or nerve-endings located in the central nervous system Whether this be so or not if their activity is altered as a result of small changes in a specific environmental quantity (in this instance in the [illegible]) and if, as a result, complex motor effects are [illegible] through the central nervous system, then these structures are receptors in the ordinary sense

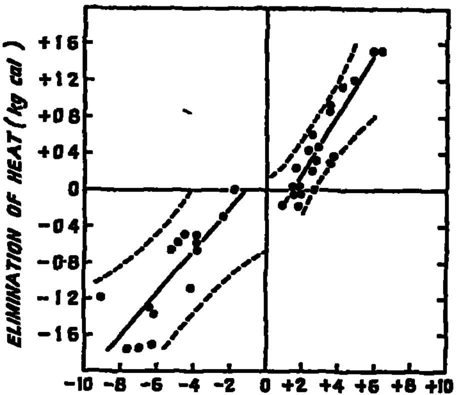

Fig 5—Relation between increase or decrease in elimination of heat from hand and amount of heat change producing it Stimulus was intravenous infusion of either hot or cold saline solution (Snell, *Journal of Physiology*, 1954)

The idea of a central structure responding to changes in blood temperature also occurred to Gibbon and Landis (1932), who shortly afterwards published experiments similar to mine and who also obtained vasodilatation in the hands by immersing in hot water the insensitive lower extremities of a patient with a transected spinal cord—the human counterpart of Winkler's experiments

Some of the most important evidence regarding the activity of the central receptor was provided by Snell (1954), who infused hot and cold saline solution intravenously in normal men and was thus able to measure accurately the heat transfer and the ensuing vascular response in the hand He found that the least heat transfers invariably causing vasoconstriction and vasodilatation were losses of 3 8 and gains of 2 4 kg calories respectively He further showed that there is a linear relationship between the sizes of heat transfer and vascular response of the hand, and that the slopes of the two regression lines for heat and cold do not differ significantly (fig 5) This would be consistent with the existence of a single set of receptors responding either to a rise or to a fall of blood temperature Furthermore Gerbrandy, Snell, and Cranston (1954) demonstrated a linear relationship between the size of the vascular response of the hand (in kg calories) and the area of the curve of mouth-temperature (in °C per minute), provoked by intravenous infusions of hot saline solution, though the rectal temperature is commonly uninfluenced This disposes of one of the main difficulties that other workers have found in recognising the activity of the central receptors, because they have usually measured, as I measured, the rectal temperature, and observed no clear relationship between changes in rectal temperature and changes in vasomotor tone

These experiments of mine were almost certainly misleading in the idea that they left about the importance of the temperature receptors in the skin Man is a terrestrial and not an aquatic animal, and the immersion of a part in very hot or very cold water, though a convenient laboratory device, is not a stimulus that we or our ancestors frequently encountered The vasoconstriction evoked is quite properly seen as merely an aspect of the vasoconstriction that follows any strong sensory stimulus (Hallion and Comte 1894)

Kerslake and Cooper (1950) found that exposing the trunk of a subject to radiant heat induced, after a latency of about 25 seconds, a rise in heart-rate and a vasodilatation in the hand They have shown that similar chang can be induced by so exposing the lower limbs, and th the responses persist when the circulation to the lowe limbs has been arrested The responses are unquestionably reflex Curiously they disappear when the lowe limbs are sympathectomised The receptors are thu probably not those that subserve the sensations of hea and cold

Now, there are two aspects of the behaviour of the receptors which require to be further explored becau they are so clearly important

The first, arising from Kerslake and Cooper's paper (195 is the suggestion that the reflex is not fatiguable, for irradiatin the trunk for 25 minutes gave vasodilatation persisting as long

The second, supported by the preliminary results of Coope Ferris, and Mottram (1956), is that there is a reflex vasoconstriction to exposure to a cold body, that the responses negative and positive radiation are quantitatively related to th radiant energy lost or gained, and that the lines relating the may be continuous

If these points are finally established, then it is clear tha we have to consider the activity of a set of receptors i the skin which are quite different from those ordinaril recognised and which may reasonably be supposed t have a profound effect on temperature regulation

To sum up, blood-flow through the skin and probabl of the mucous membranes of the mouth and nose (Mudd Goldman, and Grant 1921) is regulated partly by reflexe from receptors in the skin, probably different from thos serving sensation, and partly by the activation of a centra structure, perhaps a specialised receptor, that respon to changes in blood temperature of about 0 2°C

Control of Sweating

Leonard Hill (1921) first showed clearly that sweatin is under the control of a central temperature-sensiti mechanism He found that the sweating induced b sitting in a room at 38°C is stopped in a minute or tw by putting the hands under a cold tap If the circulatio to the arms was occluded, sweating did not stop unti after the pressure in the cuffs was released There wa no fall in rectal temperature, but calorimetric experimen showed that the rate of heat loss by the hands immerse in cold water was 0 6–1 2 kg cal per minute in t experiments

This, then, is a heat transfer of the same order as h been found to cause vasoconstriction A great deal o work has subsequently been done which shows a stro correlation between rate of sweating and deep sk temperature (Kerslake 1955) Since there is also a correl tion with rectal temperature, some have thought th sweating is controlled by receptors in the skin, and so by central receptors This is a very difficult problem skin blood-flow is in fact controlled by central temperatu receptors, and if sweating is similarly controlled, a corre tion between skin temperature and sweat-rate might b expected Hill's experiments still stand as the mo definitive

Control of Shivering

It is an old controversy whether the additional he production that can be evoked through the thermo regulating mechanism is or is not solely effected throu shivering Shivering is probably the main, if not the so mechanism Electromyographic records show that, first, the muscle units fire off at different frequencies out of phase with each other (Burton and Bronk 193 the discharges become phasic The former irregular raction has been called thermal muscular tone , the sic discharge constitutes shivering Cutting the terior roots abolishes shivering but not thermal tone nan shivering is mediated through the anterior roots, vated not by the pyramidal tracts but by the lateral ospinal or rubrospinal tracts (Uprus et al 1935)

ather less is known about the afferent side of control, it seems that the same two sets of receptors, peripheral central, are concerned It is a common experience t, if a subject is cold, either the sudden application of to the skin or a blast of cold air may induce shivering a few seconds—a time interval which is too short for er than a reflex from the skin On the other hand, if a ject is warm—e g , after exercise—the same stimuli y not produce shivering Experiments on dogs emingway 1939) on the whole support these impressions ned from man However, the strongest evidence for activity of a central thermosensitive mechanism was t provided by Sherrington (1924), who showed that mersion in cold water of the insentient hindquarters of log whose spinal cord was severed produced, after a ent period, shivering in the normally innervated fore-arters

Thermotaxic Centre

Evidence concerning the thermotaxic centre is of two ids—namely, loss of this function when parts of the ain are removed, and display of the relevant motor enomena when parts of the brain are stimulated, par-ularly by heat or cold

Isenschmid and Schnitzler (1914), by careful section of the ain stem in rabbits, showed that that part of the diencephalon uated in front of the posterior edge of the optic chiasma is necessary for heat regulation, and that the integrity of the ber cinereum is essential

Ranson and Ingram (1935) produced coagulation necrosis the brain stems of rhesus monkeys and allowed them to cover In seven monkeys the ability to protect against se of blood temperature was lost , in these the lesion was lateral in the rostral part of the anterior hypothalamus ne monkeys became cold when removed from the warm om , all three had bilateral lesions destroying the posterior rt of the lateral hypothalamus, in the region lateral to the amillary nuclei

Evidence for the spatial separation of centres protecting gainst overheating and overcooling was also obtained in the t by Clark, Magoun, and Ranson (1939) and in the dog by lair and Keller (1946)

A major difficulty in investigating the responsiveness of ie brain to changes in its temperature is the profound ffect of anæsthesia on the vascular system In man eneral anæsthesia is commonly associated with an icrease in skin blood-flow and a decrease in renal blood-ow (Lee et al 1953) In the dog Hemingway (1941) howed that pentobarbitone, amylobarbitone, and ether ll reduced the ability to protect against low temperatures

Kahn (1904) heated the carotid arteries of rabbits and its and observed flushing of the skin when the mouth-mperature had risen by 2°C Barbour (1912) circulated ater through a metal tube in the region of the corpus striatum ad found that 42 C was the lowest temperature that caused ushing, and 33 C the highest that caused paling, of the ears f rabbits These changes are clearly much too large to present the activities of the central receptors—at least as ey are known in man

Magoun et al (1938) introduced paired insulated 'Nichrom' ctrodes into the hypothalamus of cats under urethane esthesia with the Horsley-Clarke stereotaxic instrument and heated the region between them with a high-frequency diathermy current They found that heating an area of the hypothalamus dorsal and cephalad to the optic chiasma produced acceleration of respiration and sweating of the fore-pads Similar results were obtained in cats and dogs under nembutal, chloralose, and urethane anæsthesia by Folkow et al (1949) In cats the responsive region was 8 mm caudal to the anterior border of the optic chiasma In this region a temperature rise of not more than 0 5°C produced slight cutaneous vasodilatation after a latency of 15–20 seconds This is the strongest evidence concerning the location of a central temperature receptor

Hemingway et al (1940) had come to the same conclusion They placed gold electrodes on the ventral surface of the brain, anteriorly between the optic tracts and over the chiasma, and posteriorly between the pituitary stalk and mamillary bodies A month later shivering was induced by cold Heating the anterior electrode with a diathermy current stopped shivering , heating the posterior electrode did not

Ström (1950) systematically explored the hypothalamus of anæsthetised cats with one electrode cooled by water and failed to observe any alterations in cutaneous blood-flow or respiratory rate when the anterior or posterior hypothalamus was cooled to 31–36°C On the other hand, if the anterior hypothalamus was so cooled while heating by diathermy was in progress, the cutaneous heating produced by diathermy disappeared Cooling the carotid arteries was not effective in cooling the hypothalamus but produced vasoconstriction that was thought to be a reflex from cooling the facial skin

It has been very generally concluded from the destructive experiments that there are two thermotaxic centres one of which protects against cold while the other protects against heat In fact all the evidence displays is that the tracts subserving these two functions pass through different areas of the hypothalamus and can be separately interrupted The evidence that heating a quite local area of the hypothalamus produces changes that duplicate those elicited by exposing the body as a whole to heat is very strong evidence that this is the site of the central receptor responding to heat , as Folkow et al (1949) have shown, the rises of temperature are too small to represent a non-specific stimulus The evidence would be stronger if the same area had been shown to respond to cold, but this is much more difficult technically, and so far the sole evidence is Strom's (1950) observation that cold will inhibit the effects of heating

Thermotaxis as Example of Homœostasis

Having considered the parts, we may now try to view the whole, to see how the various mechanisms are integrated and coordinated to regulate body temperature As we have seen, there are three effector mechanisms in man—shivering, cutaneous vasoactivity, and sweating—which regulate heat production and heat loss All are effected through the nervous system, as are the other two devices of mammalia, polypnœa, and piloerection These effector mechanisms require the integrity of the central nervous system up to and including much of the hypothalamus We may assume that the nervous pathways extend cephalad to about this point in the central nervous system

So far the problem is non-controversial What is controversial is the way in which this mechanism is activated A commonly held view is that of Bazett (1949) supported by Burton and Edholm (1955) They consider that cutaneous reflexes play a dominant role and that the chief thermal receptors are those of the skin " There is no need to postulate a specialised ' thermal receptor ' in the brain, for which we have no histological evidence whatever '

They think that there is "definite evidence of the anatomical and physiological separation of the heat loss and heat conservation centres," and they think that the evidence that exists for some central control can be explained by the effect of temperature on the relaying and conducting functions of these centres

The evidence collected here leads me to think that this is not a correct assessment of the situation To my mind the evidence points strongly to the dominant role of the central receptor or receptors and the subsidiary role of the cutaneous receptors Whether the central receptors are situated in the hypothalamus or not is important but not essential to the concept These several receptors give rise to nervous impulses which are, no doubt, summated and integrated in the brain and excite the various efferent mechanisms

I think we can take it as established that the thermal receptors of the skin are concerned with temperature regulation By reason of their situation and of the reflex responses to which they give rise, they are most probably concerned in the immediate protection of the body against hot and cold environments For example, Sherrington (1924) noted that, when a normal dog was removed from its pen at 26 6°C to a cold room at 1°C, the vaginal temperature at the end of 40 minutes showed a slight rise Again, Kerslake and Cooper (1950) observed that, when the limbs or trunk are exposed to radiant heat, the reflex vasodilatation in the skin is regularly accompanied by a fall in mouth temperature In each of these two instances the actual change in central body temperature is the reverse of the environmental change; reflexes from the skin have overcompensated for the change in the *milieu extérieur* However, we still have a great deal to learn about the behaviour of these receptors I used to think that, as François-Franck (1876) first pointed out, they were easily fatigued It seems probable, however, that the receptors are not themselves responsible for sensation and their detailed behaviour, in so far as this is manifested by reflex changes, remains to be explored

I think we can take it as established that a central receptor or receptors are also concerned in temperature regulation; their activity has been demonstrated in the control of cutaneous vasomotor tone, of sweating, and of shivering

In considering the relative importance of these receptors one major fact stands out—namely, that the constancy achieved in the temperature of the central parts of the body is of a very high degree, whereas that of the skin is not This consideration alone makes it probable that the central receptors play a dominant, and the skin receptors a relatively subsidiary, role in the long-term regulation of temperature This case remains incomplete in the sense that the location of the central receptors is not yet proved, nor is it known by virtue of what physicochemical peculiarity they respond in the way that they seem to Thus, though there is suggestive evidence that areas in the hypothalamus close to the optic chiasma respond appropriately to a rise of temperature, there is virtually none that they respond to a fall Nor is there any evidence that these areas differ in their histological appearance from other cells of the hypothalamus (Eliasson and Strom 1950)

The concept of the mechanism regulating temperature in man developed here is thus as follows Small deviations in central body temperature are opposed by corresponding deviations in cutaneous vasomotor tone Larger deviations upward or downward are opposed respectively by sweating and by shivering The effector mechanisms are activated chiefly and persistently by central receptors, less importantly and intermittently by cutaneous receptors Coordination and integration take place within the central nervous system, probably in the hypothalamus or below The spinal tracts concerned in the control of shivering and vasomotor tone are probably different, and this may account for the way in which protection against heat and cold are differentially affected by localised hypothalamic lesions Except in this sense it is unlikely that there are different centres for the regulation against heat and cold

Comparison with Other Homœostatic Mechanisms

The concept here presented of the way in which the temperature of the *milieu intérieur* is regulated assigns a dominant role to receptors that appreciate changes in this milieu—receptors that may properly be called proprioceptors, as opposed to the exteroceptors of the skin To put this concept into perspective it may be compared with the mechanisms regulating blood-pressure and blood-sugar

Blood-pressure

The old concept of the regulation of blood-pressure was that both the peripheral resistance and the cardiac output were under the control of autonomous medullary centres—the vasomotor, cardioinhibitor, and cardio-accelerator centres (see Bayliss 1923) The activity of these centres was affected by impulses from the various sensory nerves and the higher centres, and by oxygen and carbon-dioxide content of the blood

It was always difficult on this concept to see how the blood-pressure was so nicely regulated However, the work of Hering and Heymans has shown how profoundly defective this concept was We now know that perhaps the most important regulators of blood-pressure are the baroreceptors of the carotid sinus and the aortic arch; alterations in pressure in these proprioceptors alter the number of impulses originating from them, and so lead to the reflex initiation of changes in heart-rate and vasomotor tone that tend to oppose the alteration The effector paths, including those to the adrenal medulla, are nervous, and the mechanism is thus almost a perfect analogue for that here presented as responsible for temperature control

In addition the renin-hypertensin system is probably concerned in the control of arterial pressure As to how that control is effected I have nothing material to add to what I presented fourteen years ago (Pickering 1943); it is, however, unlikely that a nervous mechanism is involved This mechanism, if it is indeed concerned in blood-pressure control, has no known analogue for temperature

Blood-sugar

The control of the blood-sugar level is quite different from either of the foregoing The first line of defence seems to be the taking up or discharge of glucose by the liver and muscles from or into the blood This control is effected largely through increase or decrease in the secretion of insulin by the pancreas, which is itself controlled by the sugar content of the blood perfusing it The second line of defence is the mobilisation of glucose from the liver due to the action of adrenaline, secreted in response to the effects of low blood-sugar level on the cells of the central nervous system

Here, then, we have a chemical quantity, regulated argely by chemical means—i e, by hormones, which are hemselves controlled by the blood-sugar

The principle in all these three examples is the same —i e, if a particular quantity in the *milieu interieur* is egulated within narrow limits, the regulating mechanism s chiefly activated by alterations in that quantity It eems to me not improbable that this principle is of quite eneral application

(*To be concluded*)

"Few health workers have had a serious chronic illness and so the world of the patient is unfamiliar to them They may be familiar with his lungs, joints, blood pressure, or blood sugar concentration, but his outlook on life, likes and dislikes, private terrors, and feelings about his family can be as unfamiliar as the uncharted bottom of the sea The worker should remember that chronic illness *is* a way of life He must be careful and tender of feelings, but decisive and affirmative Patients are made more anxious by too passive an approach "—*Prevention of Chronic Illness* Commonwealth Fund Harvard University Press 1957

HYPERTENSION FOLLOWING X-IRRADIATION OF THE KIDNEYS

FOR many years it has been known that X-irradiati may damage the kidneys, but the clinical importance this has been recognised only recently (Luxton 1953)

Schulz and Hoffmann (1905) were the first to study t histological changes in the kidney following experimen irradiation In rabbits they observed a great increase interstitial tissue, together with atrophy of the tubules a glomeruli which they attributed to compression by the n connective tissue The blood-pressure was not measured, b in one rabbit examined after 48 days (the longest period observation after irradiation) muscular hypertrophy of t renal vessels was noted

Hartman et al (1926) irradiated dogs' kidneys in si using high-voltage X-rays to avoid excessive damage to t abdominal wall They confirmed the earlier finding of a gre increase of connective tissue replacing the tubules t glomeruli were not decreased in number, but in dogs observ for more than 3 months after irradiation they exhibited vario degrees of hyaline atrophy Blood-vessels of all sizes in t kidney showed thickening of their walls and in many cas obliterating endarteritis Hypertension was noted in the long-standing cases, and death was usually due to renal failu Later the same workers (Hartman et al 1927) demonstrat hypertension, renal failure and histological lesions when o kidney of a dog was exteriorised and irradiated, the other bei removed and the rest of the body protected by lead O'Ha et al (1926) made similar observations in rabbits

Essentially the same findings were obtained in rats Bennett et al (1953), who used whole-body irradiation und anoxic conditions to lower the mortality-rate With a dosa of 600–1400r, nephrosclerosis and moderate hypertension we observed after 300 days

In man, evidence of renal damage was reported Warthin (1907) in patients irradiated for leukæmia Mu later

Dean and Abels (1944) described a most interesting ca of a woman, aged 20, with an abdominal mass who receiv 4600r to the left upper quadrant of her abdomen in 25 day 7 years later she was found to have hypertension with eviden of impaired function in the left kidney At operation th kidney was found to be shrunken and fibrotic, and after removal the blood-pressure returned to normal

Zuelzer et al (1950) reported a form of glomerulonephri in three children who had received therapeutic irradiati (5000–6850r in 4 months) to the renal area All of them di from renal failure and hypertension within 7 months of t first irradiation Renal changes included lesions of t glomerular capillaries and Bowman's capsule, tubular atrop and necrosis, and interstitial fibrosis, no blood-pressu measurements were recorded

The infrequency of such reports was no doubt due to t rarity of the conditions for which the upper abdomin areas were subjected to high-dosage irradiation

Luxton's series—the largest yet published—consist of patients who during treatment of testicular tumou received intensive irradiation (2300r in 5 weeks) over a wide field including both kidneys. Of those at risk, twenty-seven (about 20%) developed albuminuria, nearly all had hypertension, and in many there was renal impairment.

No serial studies of blood-pressure, urine, or renal function were made from the time of irradiation, because the renal complications were unexpected. Thus many of the cases could be reviewed only retrospectively. From the evidence available it appeared that the blood-pressure rose after an interval of at least 6–12 months after irradiation.

Luxton classified his series clinically into acute and chronic radiation nephritis and benign and malignant hypertension. In the two cases classified as malignant hypertension albuminuria was present when the urine was first examined, but one patient had normal renal function: both patients died within 7 weeks of the onset of symptoms.

Of the whole series seven patients died, and necropsy material from four was studied and reported fully by Russell (1953). In three necropsies on patients who presented with "acute radiation nephritis" the important histological lesions were thickening of the renal capsule, diffuse interstitial fibrosis, tubular degeneration, glomerular hyalinisation, arterial hypertrophy, and arteriolar hyaline necrosis. This picture is in nearly all respects similar to that described in laboratory animals. In one case presenting with malignant hypertension there was again widespread interstitial fibrosis, with a tendency to form dense wedges of sclerotic atrophy. Most of the glomeruli were abnormal and showed partial or complete hyalinisation and occasional hæmorrhagic infarction; the tubules were largely atrophic. Hyaline arteriosclerosis and endarteritis fibrosa of the interlobular arteries, and fibrinoid necrosis of arterioles, were present.

Luxton thought that fibrous thickening of the kidney capsule was a possible but unlikely cause of the hypertension, by analogy with the perinephritis observed when hypertension is produced in animals by enclosing the kidney in a 'Cellophane' capsule. However, in our studies of malignant hypertension at The London Hospital we have observed cases in which this syndrome followed irradiation of the kidneys, and in two instances there was an apparent dissociation between hypertension and irradiation sclerosis. In these, there was no evidence of diffuse interstitial fibrosis, glomerular hyalinisation, tubular atrophy, or severe thickening of the renal capsule. Indeed, the most significant histological changes in the kidneys were scattered arteriolar and glomerular necroses presenting a picture indistinguishable from that of early malignant essential hypertension.

These findings led us to the view that in certain circumstances irradiation of the kidneys might induce hypertension in the absence of irradiation sclerosis, and that in such cases renal structural changes might be predominantly secondary to the hypertension. In this paper we shall first describe two patients in whom hypertensive renal disease developed after irradiation, illustrating these two distinct patterns of renal structural damage. We shall then present a series of experimental studies in the rat, designed to clarify the relation between hypertension and structural changes in the kidney following irradiation.

Two Types of Hypertensive Renal Disease due to Irradiation of the Kidneys in Man

FIRST CASE

The first patient received deep X-ray therapy for an abdominal carcinoma and died 8 years later with hypertension and uræmia. The histological picture is the common type in which chronic irradiation sclerosis is associated with hypertensive renal lesions.

First Admission

A woman, aged 35, was admitted on March 31, 1946 (no. 40430). Swelling of her ankles had been noticed 6 weeks previously, followed by sudden pain in her right calf after 3 weeks and swelling of the whole limb.

Examination.—Signs of right femoral thrombosis; large firm upper abdominal mass, moderate ascites. Apex-beat not displaced. Blood-pressure 160/100 mm. Hg, falling to 120/80. Urine: sp. gr. 1·015, no albumin. Hb 88%, leucocytes 7300 (normal differential count). Wassermann reaction negative. Barium meal and chest radiograph normal. Intravenous pyelogram normal.

Laparotomy (April 3, 1946).—"Solid lobulated mass attached firmly to posterior abdominal wall, probably connected with pancreas." Microscopical report on biopsy specimen: "piece of pancreas, infiltrated by carcinoma composed of solid groups of small polygonal cells."

Deep X-ray therapy started on May 28, 1946. Upper abdominal baths, 3000r, 26 treatments in 35 days. During the next 12 months the ascites and abdominal mass gradually diminished. The patient ceased to attend hospital, and remained well for some years.

Second Admission (May 4, 1954)

Generalised aches and malaise for 2 weeks, and frequent vomiting for 3 days. Sallow complexion, pulse 110, neck veins distended, well-marked pulsation in suprasternal notch. Apex-beat in mid-axillary line. Heart sounds normal. *Blood-pressure* 190/115. Death occurred suddenly soon after admission.

Postmortem Findings

Kidneys contracted (left 3¼ oz., right 1½ oz.), granular subcapsular surface, cortex narrowed, arcuate arteries prominent. Great hypertrophy of left ventricle, considerable atheroma

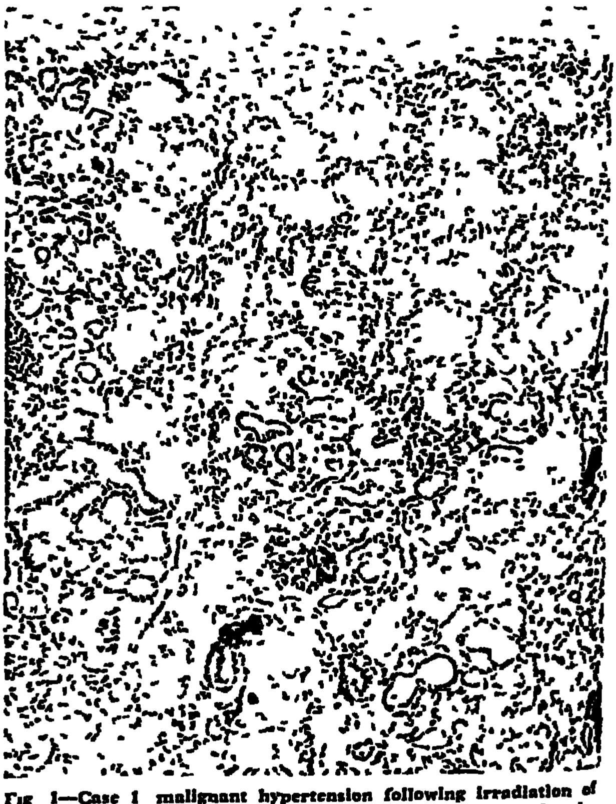

Fig. 1—Case 1: malignant hypertension following irradiation of kidneys: irradiation sclerosis of kidney. (Hæmatoxylin and eosin. × 57.)

Œdema of lungs Membrano-hæmorrhagic "uræmic" colitis No definite abnormality in or around pancreas

Histology of kidneys (fig 1)—Gross disorganisation of renal pattern, particularly in the smaller kidney, variable fibrous thickening of capsule

Glomeruli not significantly reduced in number, but more than half show hyaline degeneration of tuft and great collagenous thickening of Bowman's capsule Many hyaline glomeruli are aggregated in subcapsular areas of fibrosis (fig 1), but others are scattered throughout cortex Most other glomeruli appear normal, but a few show acute focal, sometimes hæmorrhagic, necrosis of tuft

Tubules very severe diffuse atrophy, with slight dilatation

Vessels frequent fibrinoid necrosis of afferent arterioles and interlobular arteries Endarteritis of some interlobular arteries, fibroelastic intimal thickening and medial hypertrophy of larger arteries

Interstitial tissue diffuse fibrosis, moderately cellular, with fairly uniform collagen deposition involving both cortex and medulla

This patient had a normal blood-pressure when, at the age of 35, she received irradiation to the upper abdomen over a wide field, including the kidneys When hypertension developed is unknown, because she was not observed until symptoms of uræmia appeared 8 years later The interstitial fibrosis, atrophy of the glomeruli with fibrosis of their capsules, and the changes in the larger arteries indicate a longstanding and slowly progressive nephrosclerosis Fibrinoid arterial and arteriolar necroses and glomerular necroses are evidence of terminal acute hypertensive renal damage In many ways these structural changes resemble malignant nephrosclerosis superimposed on benign nephrosclerosis, nevertheless in certain respects the picture differs from any other form of Bright's desease The features characteristic of irradiation nephrosclerosis are the diffuse interstitial fibrosis and the large numbers of fibrohyaline glomeruli, both aggregated in subcapsular fibrotic zones and diffusely scattered through the cortex

SECOND CASE

The second patient received deep X-ray therapy after orchidectomy for seminoma of testis and died 11 months later with hypertensive heart-failure and uræmia The histological picture is indistinguishable from that of early malignant essential hypertension

A man, aged 27, underwent right orchidectomy for seminoma of testis in October, 1947 Blood-pressure 140/90 mm Hg, urine normal From January to February, 1948, he was treated with deep X-ray therapy to para-aortic regions Upper abdominal baths, 3000r, 26 treatments in 36 days On Dec 18, 1948, he was admitted to The London Hospital (no 4285) complaining of severe breathlessness, weakness, and dimness of vision

Examination—Orthopnœic, Cheyne-Stokes respiration, blood-pressure 210/130, pulsus alternans Apex-beat 6th space in anterior axillary line, gallop rhythm, crepitations at left base, liver enlarged and tender, speen palpable Optic fundi bilateral papillœdema and exudates, distended veins, and narrowed arteries Urine albumin, trace to $^1/_4$ volume, sp gr 1 010, moderate number of granular casts and red blood-cells Blood-urea 150 rising to 270 mg per 100 ml Hb 34% X-ray of chest mottled shadows suggesting pulmonary œdema Condition deteriorated rapidly, death on Jan 4, 1949

Postmortem Findings

Kidneys not contracted (12 oz.), capsule adherent in parts, scattered petechiæ on subcapsular surface Great œdema of lungs, small pleural effusions Heart $17^1/_4$ oz, great hypertrophy and moderate dilatation of left ventricle, coronary arteries free from atheroma, moderate atheroma of aorta Œdema of liver and spleen No evidence of secondary growth

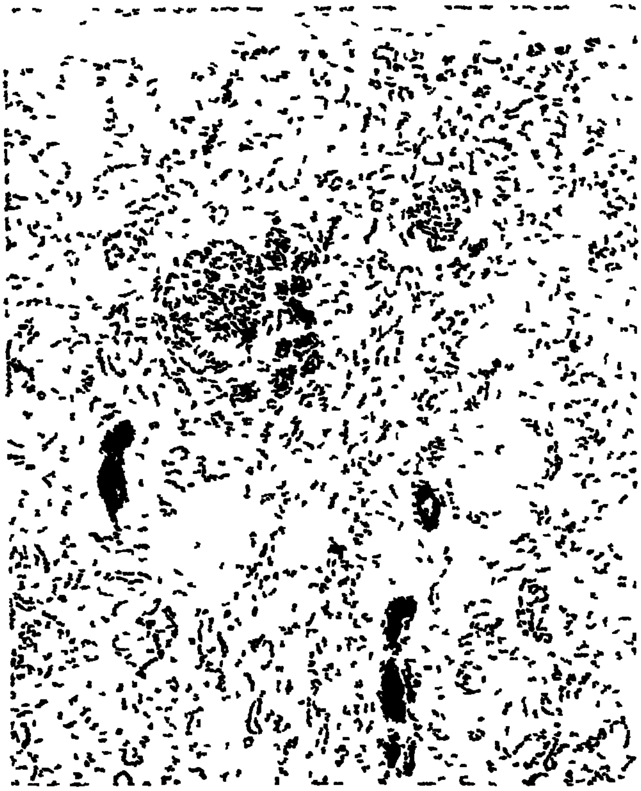

Fig 2—Case 2, malignant hypertension following irradiation of kidneys glomerular and arterial necrosis without irradiation sclerosis (Hæmatoxylin and eosin × 57)

Histology of kidneys (fig 2)—No distortion of renal pattern Focal subcapsular scarring with adhesion and thickening of renal capsule in these areas, but no general capsular fibrosis

Glomeruli not diminished in number, majority appear normal, but many show acute, often fibrinoid, sometimes hæmorrhagic necroses (fig 2) Capsular epithelial proliferation in a few glomeruli, early capsular fibrosis in others

Tubules not dilated, diffuse albuminous degeneration, severe in places, occasional hyaline droplet degeneration Some tubules contain red-cell aggregates, others altered blood

Vessels severe fibrinoid necrosis of scattered arterioles and interlobular arteries, no endarteritis Medial hypertrophy but only slight intimal elastic hyperplasia in larger arteries

Interstitial tissue diffusely increased in cortex and medulla owing largely to œdema, but with slight cellular proliferation, congestion of intertubular capillaries

This patient had a normal blood-pressure when, at the age of 28, he received irradiation to the renal areas He died of malignant hypertension less than a year later Histologically acute arterial and glomerular necroses are the most prominent lesions, a picture closely resembling malignant essential hypertension in its early stages The interstitial œdema could be explained by terminal heart-failure, of which the other organs showed ample evidence There was no irradiation sclerosis

The contrasting histological patterns in these two cases indicated the dual nature of irradiation damage to the kidneys in man It was the recognition of this which led us to undertake the following experimental investigation

Irradiation of the Kidneys in Rats

METHODS

Experiments were performed with rats of the Wistar strain

All the experiments reported here were on female rats which, at the time of irradiation, were aged 86-97 days, weighed 154-195 g, and had a systolic blood-pressure of 95-130 mm Hg The systolic

IRRADIATION OF KIDNEYS IN RATS (1100r single dose)

—	Experiment 1 (irradiation both kidneys exteriorised)	Experiment 2 (irradiation of one kidney exteriorised)	Experiment 3 (band irradiation of both kidneys in situ)
Number of rats	5	11	12
Highest systolic blood-pressure (mm Hg)	150–220	175–235	155–200 (155–230 after one kidney removed)
Interval from irradiation to hypertension (days)	126–216 (average 155)	152–266 (average 215)	167–287 (average 230)
Controls	Kidneys exteriorised without irradiation (4 rats)	One kidney exteriorised and replaced (6 rats)	Irradiation over chest (5 rats), irradiation of pelvis (3 rats), no irradiation (10 rats)

blood-pressure was measured weekly under light ether anæsthesia by a modification of the tail-plethysmograph method (Byrom and Wilson 1938) The upper limit of normal blood-pressure was taken as 140 mm Hg The rats were maintained on the stock diet and drank tap-water

X rays were from a Victor therapy set working at 200 kV and 10 mA The rays were filtered through 0 5 mm of copper plus 1 mm of aluminium The half-value layer was 1 0 mm of copper Irradiation was applied to the rats by means of special 'Perspex' applicators mounted on a base-plate fixed to the main tube housing after the normal "master-cone" had been removed The focus-skin distance was 16 cm The dose-rate at the applicator face was about 300r per minute with back scatter, and the total dosage in all cases was 1100r[1] at the proximal surface of the kidney, administered at one exposure This dosage was selected after preliminary trials had shown it to be the most consistent in producing hypertension compatible with long survival The dosage assessment, based on suitable ionisation-chamber measurements, was considered accurate to ±5% During exposure the rats were kept under ether/air anæsthesia

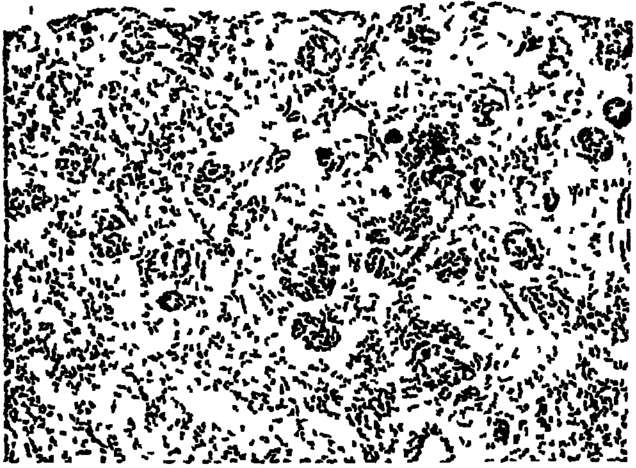

Fig 3—Experiment 1, irradiation of both exteriorised kidneys of rat: irradiation sclerosis with severe fibrinoid necrosis of arteries (Hæmatoxylin and eosin × 58)

Two forms of application were used

(1) The rats were placed prone and a perspex applicator measuring 5 × 3 cm was brought down from above until it was gently pressing on the spine in a transverse direction across the axis of the body Thus a 3 cm band of irradiation could be administered to the rat across the body at any level The upper and lower limits of the kidneys were defined by palpation under anæsthesia and marked on the shaved skin of the back The distance between these limits was less than 3 cm, and the applicator could be so placed that both kidneys received the dosage This form of irradiation we call "band irradiation of kidneys in situ" In control groups the band of irradiation was placed either above the upper or below the lower limits of the kidneys

(2) One or both kidneys were drawn out on to the rat's flank through loin incisions (after freeing the suprarenal gland), and two lead shields with central slots were slipped in opposite directions beneath the kidney with the renal pedicle lying in the slots, thus effectively shielding the rest of the body from irradiation A special perspex applicator, of kidney size and shape, was then brought into contact with the kidney, which was immediately replaced after irradiation This procedure we call "irradiation of the exteriorised kidney"

RESULTS

Experiment 1 Irradiation of Both Kidneys Exteriorised

The details of this experiment are shown in the accompanying table Although only five rats were included in this group, the results were remarkably uniform Hypertension developed in 126–216 days after irradiation (average 155 days), and the range of the maximum blood-pressure was 150–220 mm Hg Controls were provided by repeating the exact operative technique without irradiation, and all these were normotensive at the end of the observation period of 416 days

Pathological findings in kidney (fig 3)—The kidneys were examined after 1–4 weeks' hypertension They were moderately contracted

Histological examination showed severe zonal fibrosis with moderate to severe tubular atrophy Glomeruli in the atrophied areas were crowded together and showed hyaline fibrosis and shrinkage of the glomerular tufts, with slight collagenous thickening of Bowman's capsule In less damaged kidneys many of the glomeruli within the scarred areas appeared relatively normal Outside the areas of fibrosis the renal tissue either appeared normal or showed moderately severe tubular degeneration In both the fibrotic and the non-fibrotic areas of the kidneys acute fibrinoid necroses of glomeruli and arterioles were common

The kidneys of the controls showed no abnormality

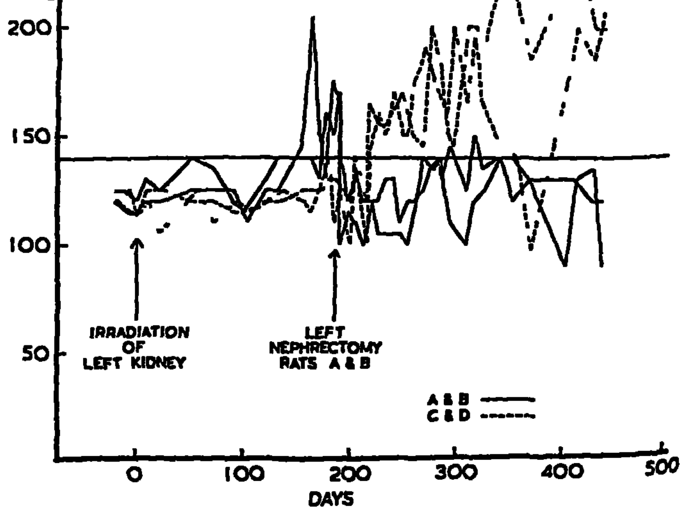

Fig 4—Blood-pressure of rats after irradiation of one kidney, with and without subsequent removal of irradiated kidney

---

[1] This dosage was measured before the recent reassessment of the röntgen (Kemp and Hall 1954, Smith 1955) and corresponds to 1175r on the new assessment

Conclusions—Following irradiation of the exteriorised kidneys in the rat, hypertension develops after a latent interval similar to that seen in man. Histologically a picture of irradiation sclerosis is produced which very closely resembles that seen in the human kidney

Experiment 2: One Kidney Exteriorised and Irradiated

Fibrinoid necrosis of arterioles and necrotic lesions in the glomeruli form a fairly constant and prominent feature of irradiation sclerosis Since it has been shown in other experiments, using the technique of renal-artery constriction, that these lesions are secondary to hypertension (Wilson and Byrom 1939), an experiment was devised to see whether this relationship could also be demonstrated in irradiation sclerosis For this purpose it was decided to irradiate one kidney in the hope that a comparison of the vascular lesions in the irradiated kidney with those in the opposite kidney might provide an answer to this problem

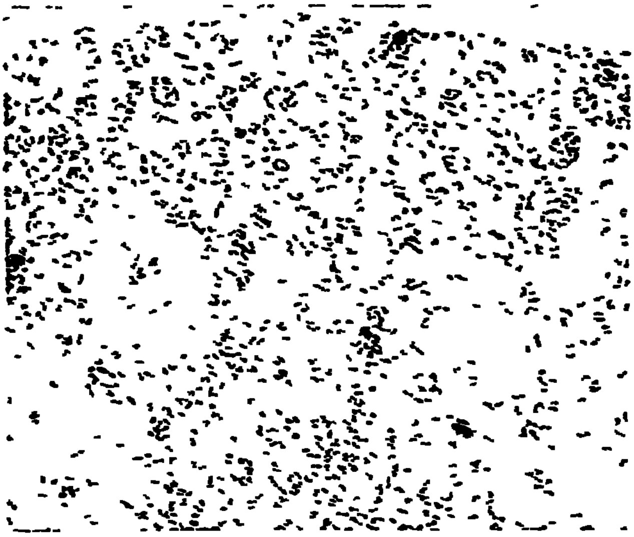

Fig 6—Experiment 2, irradiation of one exteriorised kidney of rat: irradiation sclerosis with severe fibrinoid necrosis involving large and small arteries. (Hæmatoxylin and eosin. × 58.)

The details of this experiment are shown in the table. Eleven rats were included in the series, and in six controls the operative technique was repeated but without irradiation The intervals from irradiation to hypertension were longer than in the first group with limits of 152 to 266 days (average 215 days) The maximum blood-pressure range was 175–235 mm Hg After the blood-pressure rose it remained high, but there were large fluctuations sometimes associated with hypertensive crises In two rats the irradiated kidney was removed shortly after the development of hypertension, and in these the blood-pressure fell promptly and remained normal throughout the observation period. Fig 4 shows this sequence compared with sustained hypertension in two rats in which the irradiated kidney was not removed

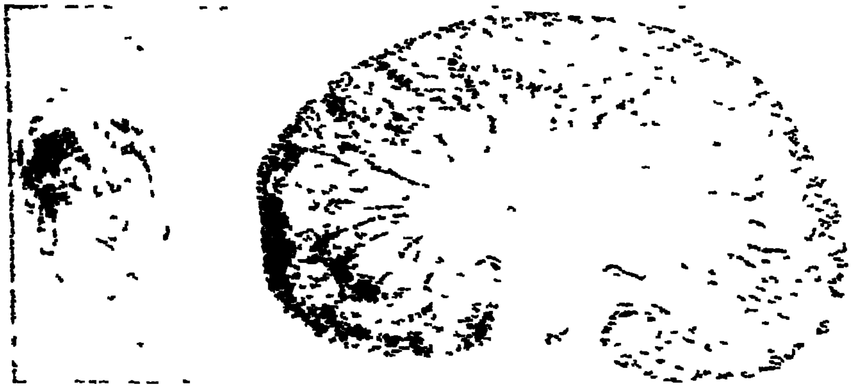

Fig 5—Experiment 2, irradiation of one exteriorised kidney of rat Irradiated kidney contracted, non-irradiated kidney hypertrophied (× 4½)

Pathological Findings in Kidneys—In nine rats of the irradiated group both kidneys were examined histologically after hypertension had been present 14–218 days In contrast with the previous experiment the irradiated kidney was grossly contracted in all the rats and the opposite kidney was considerably enlarged (fig 5)

Microscopically the irradiated kidney showed similar changes to those described in experiment 1, except that fibrosis was much more extensive and severe, and tubular atrophy and regenerative hyperplasia were more marked (fig 6) and in some instances neoplastic changes had developed The opposite (non-irradiated) kidney showed various degrees of acute and organised lesions (fig 7), which included fibrinoid necrosis of arterioles and glomeruli (fig 8), focal tubular dilatation, and hyaline droplet degeneration of the tubular epithelium These changes were identical with those observed in the opposite kidney after unilateral renal-artery constriction (Wilson and Byrom 1939, 1941)

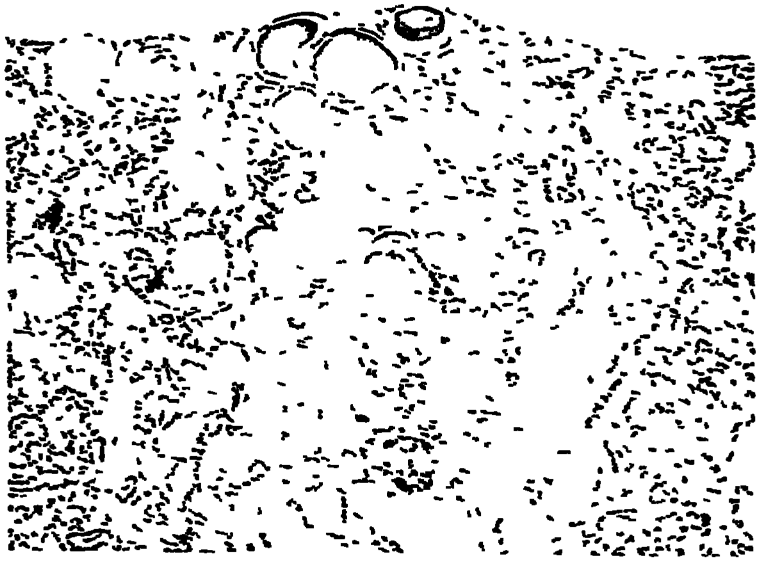

Fig 7—Experiment 2, irradiation of one exteriorised kidney of rat secondary hypertensive damage in opposite (non-irradiated) kidney (Hæmatoxylin and eosin. × 58.)

The extent and severity of the lesions in the non-irradiated kidney were roughly related to the degree and duration of the hypertension. In one rat the blood-pressure remained normal 200 days after irradiation and no lesions were found in the opposite kidney, furthermore fibrinoid arterial necrosis was not seen in the irradiated kidney of this animal although irradiation sclerosis was very severe.

When a comparison was made of fibrinoid arterial lesions in the irradiated and non-irradiated kidneys it was obvious that though similar in nature in the two kidneys, the lesions were of much greater severity in the irradiated kidney, and there was a constant tendency for larger vessels to be affected

In the two members of this series referred to above in which the irradiated kidney was removed as soon as hypertension was noted, examination of the remaining (non-irradiated) kidney showed no lesions in one case and a few scattered healed lesions in the other From a comparison with the non-irradiated kidneys which in other rats had been left in situ and which were exposed to hypertension for various intervals, it seems to be established beyond doubt that the structural changes observed in the opposite kidneys were secondary to the hypertension No lesions were found in the kidneys of the controls, and all the controls were normotensive at the end of the period of observation (430 days)

Comment—This experiment showed that, in the rat as in man, irradiation of one kidney produces irradiation sclerosis and hypertension It is shown that, if the irradiated kidney is removed soon after hypertension develops, the blood-pressure returns to normal If, however, the kidney is not removed and hypertension persists, hypertensive lesions appear in the opposite kidney and rapidly increase in extent In character they resemble the fibrinoid vascular lesions which are present in the irradiated kidney, but in the latter they are more extensive and involve larger arteries Moreover, in one rat the blood-pressure remained normal though interstitial fibrosis was severe, and in this animal fibrinoid vascular lesions were not seen in either the irradiated or the non-irradiated kidney

This experiment therefore provides evidence of two distinct pathological processes, separated in time, which lead to renal structural changes after irradiation—namely, interstitial fibrosis and hypertensive vascular damage Furthermore, from our observations in man it seemed possible that high blood-pressure and the vascular lesions resulting from it might occur independently of the interstitial fibrosis which follows irradiation The next experiment provided additional support for this hypothesis

Experiment 3 Irradiation of Both Kidneys in Situ

To reproduce more closely the conditions in man, the kidneys of the rat were now irradiated without operative interference by " band irradiation in situ " Details of the experiment are shown in the table Twelve rats were irradiated and controls received irradiation of the chest (five rats), or pelvis (three) or no irradiation (ten) Hypertension was noted 167–287 days (average 230 days) after irradiation—i e , somewhat later than in the previous experiments but comparable with the interval observed in man The maximum blood-pressure range was 155–200 mm Hg

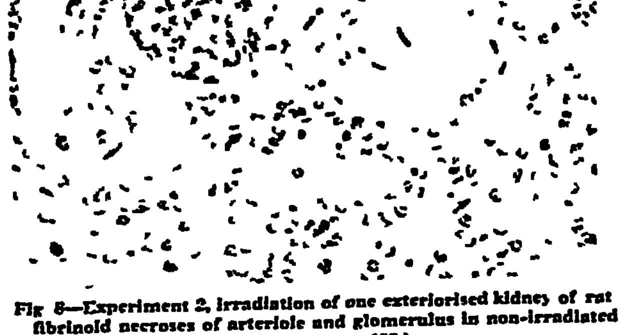

Fig 8—Experiment 2, irradiation of one exteriorised kidney of rat fibrinoid necroses of arteriole and glomerulus in non-irradiated kidney (Hæmatoxylin and eosin. × 185)

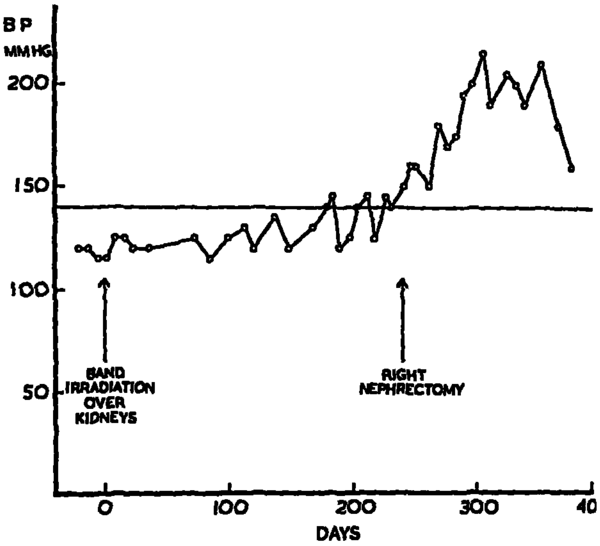

Fig 9—Blood pressure of rat after band irradiation of both kidn in situ

To follow the development of structural changes in t irradiated rats, one kidney was removed when two successi readings at weekly intervals showed a blood-pressure 145 mm or over After this operation the rats survived f periods ranging from 10 to 178 days, during which the ran of maximum blood-pressure was 155–230 mm Hg Fig illustrates a typical example

Pathological findings in kidney—The only changes fou in the *first kidney*, removed as soon as hypertension appeare were scattered focal glomerular and arteriolar necroses Th general architecture of the kidney was unchanged, and in som rats the kidney appeared normal apart from very occasion glomerular lesions (fig 10) The *second kidney* was examin in five cases, the intervals after first nephrectomy being 14, 2 34, 138, and 147 days, the postoperative maximum bloo pressures were 215–230 mm Hg in four of these ra Glomerular and arteriolar lesions with secondary tubul atrophy and focal interstitial fibrosis resembled the appearance in the first kidney but were generally much more extensive and severe and occasionally gave rise to gross disorganisation of the renal pattern These changes are illustrated in figs 11 and 12

A comparison with figs 7 and 8 indicates the remarkable similarity with the hypertensive lesions in the non-irradiated kidney in experiment 2 There was a rough proportionality between the severity of the hypertension before and after the first nephrectomy and the severity of the histological lesions in the two kidneys Thus in one rat in which the highest blood pressure was 160 mm Hg for not more than 10 days before nephrectomy, the first kidney showed minimal lesions In this rat hypertension persisted after nephrectomy for 138 days with a maximum level of 215 mm Hg, and the second kidney showed extremely severe changes

Among the controls, two of the five irradiated over the chest showed an occasional blood-pressure above 140 mm Hg, as did one of the three controls irradiated over the pelvis Scatter of radiation might explain these slight abnormalities In three rats, two of which received irradiation over the chest and one over the pelvis, isolated tubular segments appeared dilated and contained hyaline casts The corresponding glomeruli occasionally showed capsular thickening or adhesions These rats were 18–21 months old and had been normotensive throughout The lesions bore no resemblance to those in hypertensive rats and were not thought to be relevant No lesions were found in other organs in these groups

Of the rats which received no irradiation, all were normotensive throughout the 450 days of observation save one in which two readings were 145 mm Hg The kidneys in this group showed no abnormality

Comment—In this experiment irradiation of the kidneys in situ produced hypertension which was not accompanied by the irradiation sclerosis described in our previous experiments Histological examination of one kidney when the blood-pressure first became high showed slight focal necroses in arterioles and glomeruli—i e , changes which had all the characters of early secondary hypertensive lesions as described by Wilson and Byrom (1939) Longer exposure of the remaining kidney to hypertension led to various grades of renal damage indistinguishable from that found in the non-irradiated kidney when hypertension was produced by irradiation of the contralateral kidney in experiment 2 The renal structural changes observed in this experiment are comparable with those found in some patients who develop malignant hypertension after irradiation of the kidneys, as shown by case 2 (fig 2)

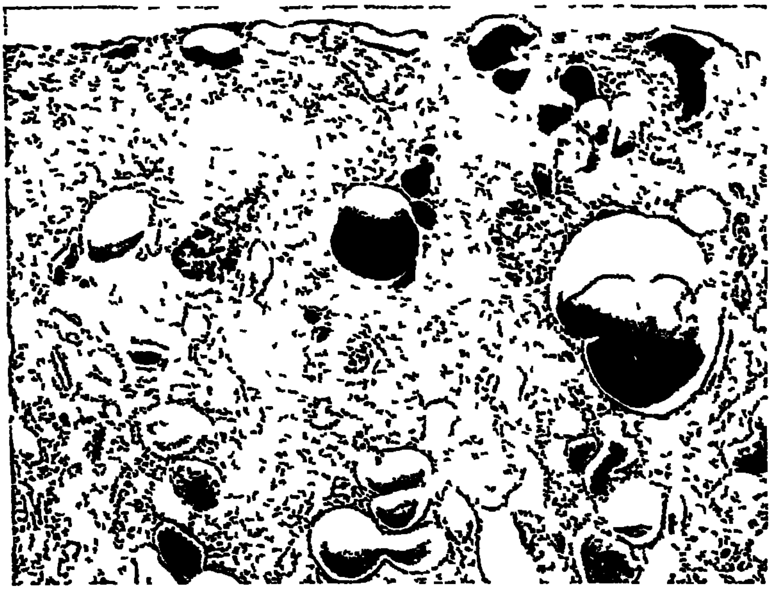

Fig 11—Experiment 3, irradiation of both kidneys of rat in situ structural changes in second kidney exposed to severe hypertension for several months (Hæmatoxylin and eosin × 58)

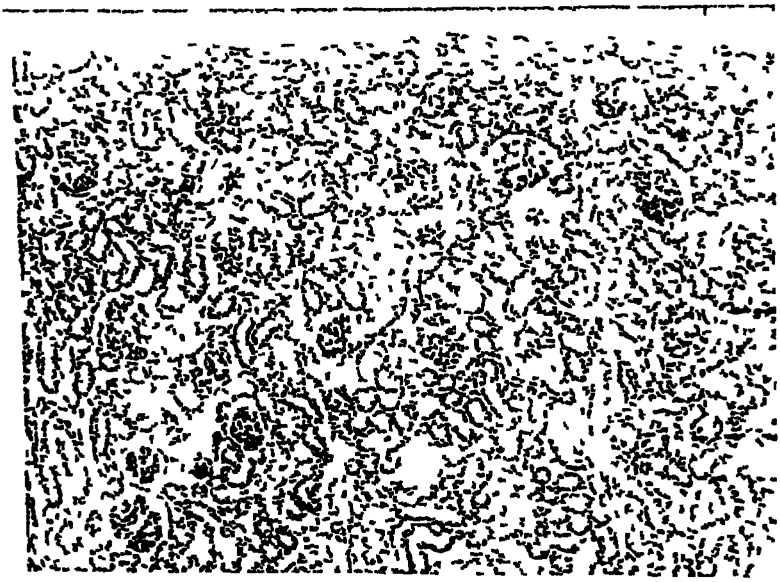

Fig 10—Experiment 3, irradiation of both kidneys of rat in situ normal appearance of first kidney removed at onset of hypertension (Hæmatoxylin and eosin × 58)

We considered the possibility that the rise in blood-pressure might be due either to renal capsular fibrosis or to hilar fibrosis causing compression of the renal artery, but we found no evidence of such lesions, and in no instance did the kidneys show signs of chronic ischæmic atrophy Furthermore, if hypertension were due to constriction of the main renal artery, we might expect, on the basis of the original experiments of Wilson and Byrom (1939), that the kidneys would be "protected" from hypertensive vascular damage

Discussion

From these observations in man and experiments in the rat we are led to conclude that irradiation of the kidneys has two distinct and independent biological effects (1) interstitial fibrosis and (2) hypertension Both in man and in the rat these effects may develop together or separately When they are associated, the structural changes in the kidney present a composite picture of the results of interstitial fibrosis and of hypertensive vascular damage The two effects have different time relations Under the conditions which give rise to interstitial fibrosis this process is far advanced when the blood-pressure first rises Hypertension, on the other hand, takes 4–9 months to develop in the rat, a latent interval similar to that observed in man

In the rat, as in man, there are many parallels between this and other forms of renal hypertension Thus irradiation of one kidney produces hypertension, and removal of the irradiated kidney may bring the blood-pressure back to normal Secondary hypertensive lesions appear in the opposite kidney, and there appears to be a relation between severity of hypertension and extent of these secondary lesions

The most important conclusion from these observations is that, both in man and in the rat, hypertension may be produced by irradiation of the kidney in the absence of the structural changes usually found in

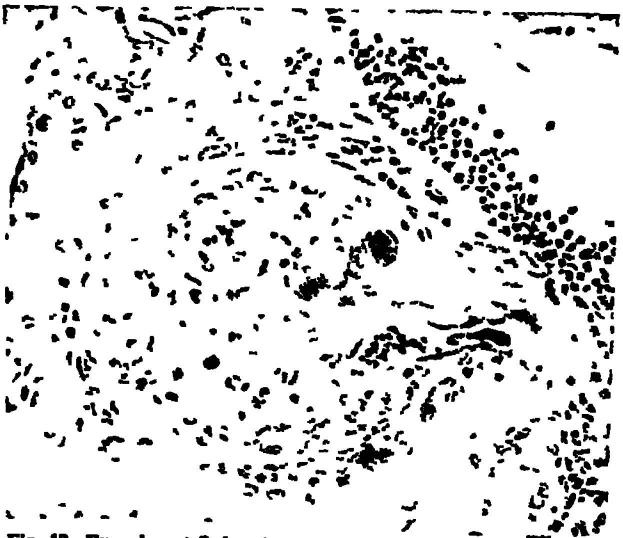

Fig 12—Experiment 3, irradiation of both kidneys of rat in situ fibrinoid necrosis of arteriole and glomerulus in same kidney as in fig 11 (Hæmatoxylin and eosin × 139)

irradiation sclerosis Later, structural changes do occur, but both in man and in the rat they closely resemble the lesions of human essential malignant hypertension, and they must be regarded as secondary to the high blood-pressure These experiments provide evidence, therefore, that renal hypertension can develop without any preceding anatomical lesion, at any rate as revealed by direct microscopy Certainly there are none of the anatomical changes in the kidney which are known to produce high blood-pressure in man or in laboratory animals

Our present experiments do not indicate how renal irradiation produces hypertension, nor do we know what factors determine the development of irradiation sclerosis on the one hand, or hypertension on the other, or indeed the two effects together Further experiments are being made to investigate these problems The latent interval of several months before hypertension appears is a regular and striking phenomenon both in man and in the rat Furthermore, we observed that, in rats which became hypertensive after irradiation of one kidney, fibrinoid necroses of the arteries were more severe in the irradiated than in the non-irradiated kidney and involved larger vessels , this suggests either that hypertension induces more severe lesions in an already damaged kidney (which is not supported by the histological findings in human kidneys when malignant hypertension is superimposed on pre-existing chronic nephritis) or that exposure to irradiation leads to greater vulnerability of the arterial wall In studies on radiation damage to the brain in rabbits (Russell et al 1949) fibrinoid arterial necrosis was found in the area of irradiation Dosage was much larger, and the post-irradiation interval rather shorter, than in our experiments Blood-pressures were not measured, but there is no reason to suspect that hypertension was present These findings suggest that, in the brain, acute arterial damage may result directly from irradiation of high intensity These observations agree with our own in suggesting that irradiation has a definite impact on the vascular system Perhaps the arteries of the kidney are rendered more susceptible to physiological stress, with the result that whatever factors control basal arteriolar tone lead to excessive vasoconstriction The long latent interval between irradiation and hypertension remains unexplained but may be related to the regeneration time of vascular tissue and the selective effect of irradiation on immature cells

The results here presented may have some relevance to the question of a renal mechanism in essential hypertension In his Croonian lectures of 1942, Sir Arthur Ellis said

> "The evidence that essential hypertension is due to primary renal vascular lesions is at present insufficient It is quite possible of course that the mechanism of production of essential hypertension is renal ischæmia, but if this is so it seems more probable that the renal ischæmia is at first functional, being due to some extrarenal factor, and is only later aggravated by renal arteriosclerosis "

Our present clinical and experimental observations seem to us to support the possibility that a functional vascular disturbance of the kidney could be the forerunner of essential hypertension

Summary

Observations in man and experiments in rats are described showing that X-irradiation of the kidneys may produce two biological effects—interstitial fibrosis and hypertension These appear to be independent of on another

Irradiation sclerosis of the kidney is a composite pictur of structural damage due to these separate processes

These observations explain the different histologic changes which may be associated with the syndrome o malignant hypertension, following irradiation of th kidneys in man

Evidence is provided that renal hypertension ma develop in the absence of any recognisable structur lesion

We are indebted to Prof D S Russell and the late Dr G W Boden for helpful discussion We wish also to thank Professo Russell for the necropsy findings, Miss Esme Nichol for technic assistance, and Mr Alan Perry, Lord Evans, and Dr F Ellis for permission to report cases under their care

PREGNANCY AND COARCTATION OF THE AORTA*

J F GOODWIN
M D Lond , F R C P
LECTURER IN MEDICINE, POSTGRADUATE MEDICAL SCHOOL, PHYSICIAN, HAMMERSMITH HOSPITAL, LONDON, W 12

COARCTATION of the aorta is not uncommon Blackford (1928) estimated its incidence at 1 in 1500 Males predominate over females in a ratio of 3 1 Pritchard's (1953) estimate for females was between 1 in 1000 and 1 in 3000 Whatever the exact figure, one may expect coarctation and pregnancy to coexist occasionally, and the improvement both of diagnosis and of surgical treatment is likely to focus attention more strongly upon management of the pregnancy in such patients Because there is some uncertainty about the influence of pregnancy on coarctation, I have attempted to evaluate the risks

Coarctation Considered Alone

The congestive heart-failure which may occur in infancy (Mustard et al 1955) need not be considered here

MORTALITY

Necropsies have shown that most patients with the "adult" type of coarctation die before the fifth decade of life

74% of Abbott's 200 patients (all of them aged more than 3 years) (Abbott 1928, Hamilton and Abbott 1928) and 61% of 104 patients reported by Reifenstein et al (1947) died before the age of 40

---

* Based on a paper read to the symposium on Non-Toxæmic Hypertension in Pregnancy, organised by the Institute of Obstetrics and Gynæcology and held at Hammersmith Hospital, London, on July 4 and 5, 1957

TABLE I—COMPLICATIONS IN 73 CASES OF COARCTATION OF AORTA

Local	Remote
Aneurysm of aorta	Cerebral vascular accidents 4 cases
Dissecting 2 cases	
Non-dissecting 4 cases	
Intercostal aneurysm 10 cases	
Manifest infection or vegetations in the coarctation 10 cases	

Total complications 30 cases (41%)
Associated cardiac lesions aortic-valve disease, 11 cases

Lewis (1933), Bramwell (1947), Campbell and Suzman (1947), Newman (1948), and Shapiro (1949) reported 94 cases of coarctation, of which 27 were fatal The average age at death from cardiovascular causes was 33, and only 7 had passed their 40th year when last seen

CAUSES OF DEATH

The causes of death are documented in the necropsies reported by Abbott (1928) and Reifenstein et al (1947) about 25% of patients died from aortic rupture or aortic dissection, 25% from bacterial endo-aortitis or endocarditis, 25% from congestive heart-failure, about 10% from cerebral vascular accidents, and 15% from other causes The highest average age at death from cardiovascular causes was 39

Campbell and Baylis (1956) reported 16 deaths in 130 patients followed for an average period of five years 7 patients died during or after operation, and the remaining 9 patients did not come to operation 6 of the patients who died were apparently in good health and died suddenly and unexpectedly, mostly in the third decade

Cleland et al (1956) reported 52 patients, of whom 40 came to resection Of the 12 unresected patients 4 died, 2 from heart-failure due to associated valvular lesions, 1 from subarachnoid hæmorrhage, and 1 from dissection of the aorta Since that paper was published, Mr Cleland has treated a further 21 cases by resection The complications in the total series of 73 patients are listed in table I Of the 61 resected patients 6 died, 5 of them from local complications (1 did not come to necropsy) Of the 30 patients with complications (whether lethal or not) 26 had complications which involved the aorta and the region of the coarctation

Local complications are common and hazardous, the more so because many are silent, and sudden death and a shortened life-span are distressingly frequent in coarctation, irrespective of pregnancy

ASSOCIATED CARDIAC LESIONS AND HEART-FAILURE

Any attempt to assess the hazards of coarctation must take into account the presence of added cardiovascular lesions

A bicuspid aortic valve was found in about 20% of necropsies by Abbott (1928) and in about 40% by Reifenstein et al (1947) Aortic regurgitation was present in nearly 25% of the 130 cases of Campbell and Baylis (1956) and tended to become more serious with increasing age Aortic-valve stenosis was present in 11% of Reifenstein et al 's series, and in 6 of Campbell and Baylis' patients Aortic-valve disease was present in 11 of the 73 cases in our own series

Mitral-valve disease, ventricular septal defect, and patency of the ductus arteriosus are less common

Cardiac lesions confer the added hazards of bacterial infection and heart-failure Cleland et al (1956) found heart-failure only in patients with severe valvular lesions 18 of 19 patients (Reifenstein et al 1947) and 7 of 8 patients (Campbell and Baylis 1956) who died of congestive heart-failure had additional cardiac disease Campbell and Baylis (1956) find that aortic regurgitation with coarctation may lead to heart-failure in the third decade, and they point out that infective endocarditis may accelerate such failure

HYPERTENSION

Hypertension is rarely severe, and, although systolic pressure may sometimes be high, the pressure is extremely labile Important hypertensive cardiovascular disease occurs only as an extreme rarity (Cleland et al 1956) Hypertension may, however, contribute to cerebral vascular catastrophes, and there is some direct relation between intracranial hæmorrhage and the level of the blood-pressure (Reifenstein et al 1947, Campbell and Baylis 1956) Moreover patients with coarctation tend to have congenital intracranial " berry " aneurysms

SURGERY

Resection of the coarctation, with or without the use of a graft, is now an established procedure The mortality is now 5–10%—usually 5% in cases without complications (Campbell and Baylis 1956) Gross (1953) reported only 2 deaths in his last 100 cases In our series (Cleland et al 1956), there were 6 deaths in 61 resected cases, including cases complicated by aortic aneurysm Resection lowers the blood-pressure (Gross 1953, Counihan 1956, Cleland et al 1956, Campbell and Baylis 1956)

Coarctation with Pregnancy

123 cases of coarctation and pregnancy have been published

Benham (1949) collected 53 cases from the literature, and Rosenthal (1955) collected 38 more published subsequently and added 5 cases of his own Porter (1955) added 1 case, Dixon and Hartley (1955) 2 cases, Gropper and Schroeder (1956) 1 case, and Espino Vela and De Castro Abreu (1956) 6 cases Campbell and Baylis (1956) mention 2 cases in their review of 130 patients with coarctation Halonen et al (1956) have published 15 more cases

To these may be added 13 cases of my own, including the 10 described by Cleland et al (1956) There is thus a grand total of 136 cases

MORTALITY

The mortality of pregnancy complicated by coarctation is 9 5% (13 cases) This mortality is in striking contrast to that of 29% in the combined series of 94 cases described by Lewis (1933), Bramwell (1947), Campbell and Suzman (1947), Newman (1948), and Shapiro (1949), and less than that of 12 3% in the 130 cases published by Campbell and Baylis (1956) The ages at death are not comparable in the different series but the average age at death in the combined series of 94 cases was 33 More-

TABLE II—PREGNANCY AND COARCTATION OF AORTA

Cases published by other workers	123
Personal cases	13
Total	136
Mortality connected with pregnancy	13 cases (9 5%)
Cause of death in 13 fatal cases	
Rupture of aorta	3 cases
Rupture of dissecting aneurysm	3 cases
Cerebral vascular accident	2 cases
Infective endocarditis on aortic valve	1 case
Unknown	1 case
Congestive heart-failure	2 cases
Pulmonary œdema	1 case
	13
Associated cardiac defects in 13 fatal cases	8 cases

(The 2 patients who died of congestive heart failure and the 1 who died of infective endocarditis had cardiac lesions in addition to coarctation)

Mortality related to total pregnancies 13 cases in 354 pregnancies (3 4%)

over, 7 of the patients of Campbell and Baylis (1956) died after operation and therefore cannot strictly be admitted to the analysis Nevertheless, the mortality-rate of coarctation in pregnancy probably does not exceed that of coarctation alone (table II)

In assessing the hazards of pregnancy it is important to know also the mortality-rate in terms of the total number of pregnancies There were 13 deaths in 354 pregnancies (mortality 3 7%) Many patients had multiple pregnancies without mishap, but it must be admitted that 7 of the 13 *patients died in their first pregnancy* *Of the remaining 6* patients, 2 died in their second pregnancy and 1 each in the third, fifth, sixth, and ninth pregnancies None of our 13 patients died (table III)

TABLE III—PERSONAL SERIES OF PATIENTS WITH PREGNANCY AND COARCTATION OF AORTA

Patients pregnant	13
Deaths	0
Patients with multiple pregnancies	12
Patients resected	10
Patients pregnant before resection	9
Patients pregnant after resection	2
Pregnancy terminated (2nd pregnancy, for aortic incompetence)	1

CAUSES OF DEATH

The normal hazards of coarctation are to be expected in addition to those of pregnancy The causes of death are listed in table II, which shows that the two commonest single causes were aortic rupture and aortic aneurysm As in previously published series, heart-failure was *found only when cardiac lesions were present* There were 3 such cases 2 of congestive heart-failure and 1 of pulmonary œdema In patients without cardiac lesions the deaths were due to rupture of the aorta and cerebral vascular accidents

Let us now consider whether pregnancy predisposes to these hazards of coarctation

Rupture of the Aorta

Aneurysm and aortic rupture are almost always due to medial necrosis of the aorta, but occasionally to infective endocarditis (Campbell and Baylis 1956) A rise in blood-pressure might predispose to rupture, but, as Reifenstein et al (1947) pointed out, the blood pressure is not especially high in those cases in which aortic rupture occurs Wide fluctuations in blood-pressure have been suggested as a precipitating cause of dissection in patients with *malignant hypertension* receiving hypotensive drugs (Beaven and Murphy 1956), and the blood-pressure is notably labile in coarctation, though probably not more so during pregnancy (Dixon and Hartley 1955) Other factors in pregnancy have also been suggested—e g, thyroid deficiency (Joule 1949) and hyperlipæmia (Schnitker and Bayer 1944)

Schnitker and Bayer (1944) reported that 24 of 49 females dying from dissecting aneurysm of the aorta (without coarctation) were, or had recently been, pregnant No proof, however, of the significance of any of these factors is forthcoming, and most authors have emphasised the importance of a rise in blood-pressure in pregnancy and labour causing the aortic wall to burst

Infection at the site of the *coarctation may lead* to an aneurysm, as in 1 of our patients Moreover vegetations may remain unsuspected upon the coarctation for a long time (Cleland *et al* 1956) and might cause serious disruption of the aortic wall before detection It is not known, however, whether pregnancy predisposes to such infection

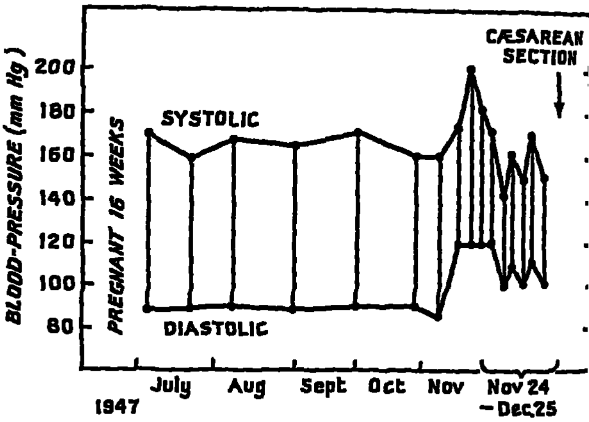

Fig 1—Blood-pressure during first pregnancy of a patient age 23 years with coarctation of the aorta

Hypertension in Pregnancy

It has been often assumed that, in coarctation, th blood-pressure rises in pregnancy and labour If it does the risks of aortic rupture and intracranial aneurysm ma certainly be increased, but Dixon and Hartley (1955 found, with coarctation, in 2 pregnant patients that th blood-pressure behaved as in normal pregnancy, fallin in the middle trimester and rising towards the end o pregnancy, except that the rise was not so high as it may b in the later months of normal pregnancy in the thre labours studied the blood-pressure did not rise appreciabl *above its upper level before pregnancy* Pritchard (1953 found the same in 2 pregnancies and labours

In two pregnancies in 1 of our patients the blood pressure showed the same tendency as that reported b Dixon and Hartley (1955)

The patient, aged 23, was first seen when sixteen week pregnant with *her* first child Her blood-pressure remaine stable throughout the greater part of pregnancy, the diastoli pressure remaining below 90 mm Hg It rose temporaril to 200/*115* mm *Hg shortly* before term but fell again befor cæsarean section was done (fig 1) In her second pregnanc her blood-pressure fell steadily and gradually and did not ris before term (fig *2*) *Two years later her systolic pressure* wa higher than at any time during her pregnancies except fo the temporary rise before her first cæsarean section

At no time in either pregnancy was her systolic pressur higher than was usual for her when not pregnant

These observations, the absence of evidence suggesting a tendency to medial necrosis of the aorta in pregnancy, and the similarity of the mortality-rates of coarctation with and without pregnancy suggest that pregnancy does not

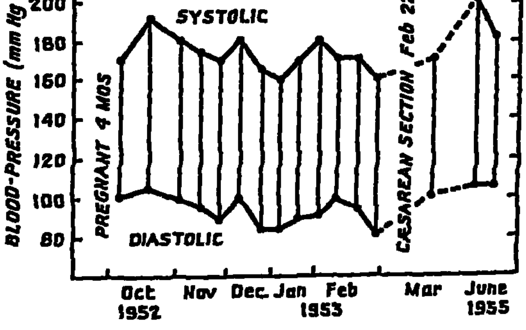

Fig 2—Blood-pressures during and after second pregnancy of same patient as in fig 1

confer an added risk to patients with uncomplicated coarctation.

Coarctation Complicated by Heart-disease

The presence of added heart-disease may radically alter the picture of coarctation, because the hazards of heart-failure and bacterial endocarditis are added. The rarity of heart-failure in adults in the absence of cardiac lesions indicates the importance of heart-disease. In pregnancy cardiac lesions assume an even greater importance. Of the 13 patients who died 8 had cardiac lesions, 3 of these died from heart-failure and 1 from infective endocarditis on an abnormal aortic valve. Appreciable valvular lesions are likely to increase in severity with the years, notably aortic regurgitation (Campbell and Baylis 1956).

It is not possible accurately to compare the risks of coarctation with added cardiac disease in the pregnant and in the non-pregnant, but it seems reasonable to suppose that the risks are likely to be greater in pregnancy. Certainly the hazard of heart-failure, which is most unusual in uncomplicated cases, is added to those of aortic rupture, infection, and cerebral vascular accident.

Of our own series of 13 pregnant patients, only 1 had important associated valvular disease—namely, aortic incompetence. For this reason her second pregnancy was terminated in the third month, and subsequently the coarctation was resected.

Management of Pregnancy

Views on management have varied widely.

Mendelson (1940) advised therapeutic abortion early in pregnancy and cæsarean section and sterilisation at term if the pregnancy is far advanced when the coarctation is detected.

Benham (1949) advised cæsarean section at term to avoid an increase in blood-pressure during vaginal delivery.

Pritchard (1953), however, analysed the maternal fatality-rate in the light of the type of delivery and found that it was almost identical in both cæsarean section and vaginal delivery (7·1% for cæsarean, 6·5% for vaginal). He advised vaginal delivery with a short second stage.

Dixon and Hartley (1955), in the light of their observations on the blood-pressure during delivery, were of the same opinion.

All writers lay stress on careful antenatal supervision, adequate rest if cardiac symptoms supervene, and prophylaxis against bacterial infection. No attempt has previously been made, however, to separate patients with important cardiac lesions from those without, and this point seems to be fundamental to the understanding of correct management.

COARCTATION WITHOUT ADDED HEART-DISEASE

It is now our view (Cleland et al. 1956) and that of others (Gross 1953, Campbell and Baylis 1956) that resection should be undertaken prophylactically in young persons. Early recognition and surgical correction of coarctation should therefore in the future reduce the problems of the management of pregnancy. Nevertheless patients with unrelieved coarctation will continue to become pregnant. It is doubtful, from published and personal experience, whether the hazards of uncomplicated coarctation are really increased by pregnancy, and it can be argued that the risks run in pregnancy are not greater than in the non-pregnant state, especially as the blood-pressure tends to fall rather than to rise during pregnancy and normal labour.

I therefore suggest that patients with uncomplicated coarctation should be allowed to go to term, and be delivered by the vaginal route, with a shortened second stage. Very careful watch must be kept during pregnancy for signs of aortic infection and of aortic aneurysm. Any increase in size of the aorta, unexplained pain in the chest or back, or pyrexia, will indicate the necessity for further investigation, including blood-cultures, so that, if an aortic aneurysm threatens to form, resection can be advised. Successful resection during pregnancy has been reported by Peterson et al. (1953), Miller and Falor (1952), and Tebow et al. (1954).

If resection is not required during pregnancy it should be advised at a suitable time after delivery. After resection further pregnancies can probably be contemplated without anxiety. Miller and Falor (1952) and Pritchard (1953) reported successful pregnancies after resection of coarctation, and 2 of our 13 patients were delivered successfully after resection.

If infective endocarditis occurs during pregnancy, a full course of chemotherapy, followed by resection, is indicated. If the pregnancy is less than twenty weeks old, termination may be advisable, but each case must be judged on its own merits. If an aortic aneurysm is suspected, resection should be done at once under full chemotherapy.

COARCTATION WITH HEART-DISEASE

When serious heart-disease is present—and especially if there is appreciable cardiac enlargement, which is very unusual in uncomplicated coarctation—a much more serious view must be taken. It is of the greatest importance to make the diagnosis early, so that the pregnancy can be terminated before the twentieth week. If the pregnancy has progressed further, the management should be that of any patient with heart-disease in pregnancy, except that resection of the coarctation may still be considered.

Considerable difficulty may be experienced in diagnosing slight degrees of aortic-valve stenosis due to a bicuspid aortic valve, since ejection systolic murmurs are invariably present in coarctation, may be exaggerated in pregnancy, and may closely resemble those of aortic stenosis. However, slight degrees of aortic stenosis are probably not important hæmodynamically, although they constitute an added hazard from infection. These difficulties underline the importance of very careful cardiological assessment early in pregnancy, and of consultation between cardiologist and obstetrician to plan management of the pregnancy and delivery.

It is not necessarily true that all cases have “ at least moderate cardiac disease ” (Pritchard 1953). Patients who have reputedly developed heart-failure in pregnancy have probably had appreciable disease of the aortic valve or other cardiac lesions previously unsuspected.

If pregnancy must be terminated because of added cardiac disease, sterilisation should not be carried out unless it is certain that neither the cardiac lesion nor the coarctation is amenable to future surgical correction.

Summary

The hazards of coarctation and the results of surgical treatment are briefly reviewed. The added risks of pregnancy are assessed in the light of personal experience and that of other workers. The behaviour of the blood-pressure during pregnancy in patients with coarctation is discussed.

Pregnancy is not necessarily an added hazard to the patient with coarctation, provided that complications are not present and that serious cardiac disease does not coexist.

It is suggested that pregnancy be allowed to continue in uncomplicated cases, very careful watch being kept for the onset of complications at the site of the coarctation, which would indicate the need for resection during pregnancy

In cases with appreciable heart-disease the pregnancy should be terminated at an early stage

I am grateful to Mr W P Cleland for his help, and to Mrs A Birbeck and the department of medical illustration, Hammersmith Hospital, for the illustrations

MANIPULATION IN THE MANAGEMENT OF CHRONIC LOW BACKACHE DUE TO "LUMBOSACRAL STRAIN"

R A Bremner
M B Edin, F R C S, F R C S E
SENIOR REGISTRAR, DEPARTMENT OF ORTHOPÆDIC SURGERY,
THE MIDDLESEX HOSPITAL, LONDON, W 1

A REVIEW of cases of chronic low backache seen in the orthopædic department of the Middlesex Hospital in recent years has shown that a very high proportion have been classified as "lumbosacral strain"

The term "lumbosacral strain" is not an ideal one, but in our present state of ignorance regarding the exact pathology of such cases it is concise and useful for classification The general pathological concept is that of a chronic localised disc degeneration, usually at the L5–S1 level, with associated derangement of the corresponding posterior joints and ligaments, from which pain presumably arises

In the early stages of the lesion the condition of the posterior joints is essentially a subluxation or "instability", with associated ligamentous strain, but in the later stages a true osteoarthritis, the outcome of long-standing mechanical derangement, develops and can be clearly demonstrated by oblique radiographs of the lumbosacral spine

The ætiology may well vary from case to case In some there seems to be an insidious primary degeneration of the disc, whereas in others a traumatic incident may be the cause of the damage (Newman 1952) However that may be, these cases form a fairly typical clinical group of large dimensions Cases presenting evidence of nerve-root involvement or of generalised lumbar spondylosis are excluded from this group

It is our belief that, in the great majority of such patients excluding the very few in whom symptoms are sufficiently disabling to warrant consideration of lumbosacral fusion, the long-term management lies in teaching them to "live with their back," with suitable adjustment of activities and posture With an intelligent patient, reassurance and advice along these lines may be all that is required, but the average hospital patient, sent for the advice of a "specialist", expects something more positive in the way of treatment

Of the many forms of active palliative treatment possible, "manipulation" is undoubtedly the most convincing to the patient Indeed, if it is not offered many will subsequently seek advice elsewhere In view, however, of the numbers involved and the fact that we are dealing with what is usually no more than a "nuisance disease", any hospital treatment should be as far as possible "definitive", so that clinic and physiotherapy department do not become inundated with these cases

The object of this investigation was an essentially practical one—to discover whether manipulation of the lumbar spine under general anæsthesia gives a sufficiently high proportion of immediate satisfactory results in this type of case to justify its routine use, with the narrow twin objectives of giving the patient a "good start" in carrying out the general regime suggested above and of providing an avenue of early disposal of these cases from the orthopædic clinic as "satisfied customers"

Clinical Material

The early results of manipulation in 250 consecutive cases diagnosed as lumbosacral strain, in which manipulation was done as the primary treatment, were analysed There were 84 males (average age 39) and 166 females (average age 36) of whom 116 were married and 50 single

Routine Management

"Orthopædic" manipulation of the lumbar spine was done under general anæsthesia with complete relaxation This was followed by an average period of two weeks' physiotherapy, to instruct the patient in simple spinal exercises and in correct posture and techniques of lifting and bending All the patients were treated as outpatients

Assessment of Results

Physical signs are few or absent, and therefore assessment must be largely subjective The following classification was used, based essentially on the patient's own report at the first visit following treatment

Group I, "*cured*" complete dramatic relief of all back symptoms

Group II, "*improved*"

(1) Much improved, to a degree where the patient felt that no further active treatment was required, although some residual symptoms persisted

(2) Some improvement, but symptoms *still present* which the patient considered significant, progressing to group (1) after further physiotherapy

(3) As in group (2) but adequate comfort attained only by wearing a lumbosacral corset

Group III, "*no change*'

(1) Not helped by manipulation or any further treatment

(2) Subsequently reporting benefit from the provision of a lumbosacral corset

Group IV, "*worse*'

(1) Made worse by manipulation and not helped by any further treatment

(2) Subsequently reporting benefit from the provision of a lumbosacral corset

The results obtained were as follows

Group	*No of cases*	
I	25 (10 0%)	(86 8%)
II (1)	136 (54·4%)	
II (2)	20 (8 0%)	
II (3)	36 (14·4%)	
III (1)	6 (2·4%)	(13 2%)
III (2)	18 (7 2%)	
IV (1)	4 (1 6%)	
IV (2)	5 (2·0%)	

Discussion

Although the primary aim was to assess the practical value of manipulation in the management of "lumbosacral strain", the composition of the group of 250 cases studied is of some interest. The ratio (1 to 1 8) of males to females confirms the clinical impression that this type of backache is more common in females than in males Were externally applied strain an important ætiological factor, one would expect the condition to be more common in males

Two possible predisposing factors in the female immediately come to mind the greater lumbosacral angle, which would increase the shearing strain on this region, and the possible effects of pregnancy and childbearing The latter possibility has not been studied in detail, but the ratio of 2 3 to 1 of married to single women does not suggest that childbearing has been an important ætiological factor in this series, in view of the normal ratio of married to single women in the age-group under consideration

There is no more controversial treatment in the management of backache than "manipulation" Opinions vary sharply from those of the "osteopathically" inclined, who would have us believe that virtually all backache can be cured with certainty by manipulation, often involving very specialised manœuvres, to those who hold that manipulation has no place in the reputable management of backache in orthopædic practice The latter are wont to attribute any success of the former to psychological influences Although this possibility cannot be completely ruled out, the patients in this series were not subjected to any psychological pressure In other words, no effort has been made to "sell" manipulation as a certain cure for all their ills Manipulation was done by different operators working on anæsthetised patients The technique of manipulation was that of general orthopædic manipulation of the lumbar spine, aiming to put the lumbar spine through a complete range of movement It is therefore reasonable to assume that the results obtained are in some way due to the physical manœuvre of manipulation and therefore capable of general repetition

Although only 10% of the patients were dramatically "cured", it was possible to discharge 64 4% (group I plus group IIa) at the first clinic visit after manipulation as "satisfied customers" In this group both our objectives have been achieved A further 22 4%, however, reported some improvement, hence manipulation was worth while from the patient's point of view in 86 8% of cases In only 3 6% was any harm done, inasmuch as the patient felt worse after the manipulation, and in 9 6% the manœuvre was a waste of time for all concerned

23% of the patients were ultimately fitted with a lumbosacral corset, and it might well be argued that this might have been more expeditiously applied as the primary management Unfortunately a review of the material has not revealed any common factor which might be assessed before manipulation to forecast the likely result The ratio of males to females in all groups closely paralleled the ratios of the totals The state of the pathological process, judged clinically and radiographically, did not prove any guide to the likely subjective improvement following manipulation, nor did any particular age-group respond especially well

We may conclude that manipulation of the lumbar spine under general anæsthesia, although entirely empirical, produced results in this group of patients which go far towards fulfilling the aims set out above for the active palliative treatment of "lumbosacral strain" in hospital practice Manipulation provides one satisfactory practical means of managing this ever-present problem in the orthopædic clinic

Summary

Long-term relief in cases of "lumbosacral strain" depends mainly on the patient's ability to adjust posture and activities to the limitations of the spine

Manipulation under general anæsthesia gives a sufficiently high proportion of immediate satisfactory results to justify its routine use as a palliative measure in the hospital management of such cases

I wish to thank Mr Philip Wiles and Mr Philip Newman, under whose care these patients were, for permission to publish this material and for help and advice in the preparation of this paper

SURGERY DURING LONG-TERM TREATMENT WITH ADRENOCORTICAL HORMONES

A J Popert
M.B Lond, M R.C.P
DAN MASON RESEARCH FELLOW

P S Davis
M.A, M.B Cantab, M.R.C.P
SENIOR REGISTRAR

RHEUMATISM DEPARTMENT, WEST LONDON HOSPITAL

Although the place of the adrenocortical hormones in the treatment of rheumatoid arthritis remains controversial, they are now often used in the long-term management of this and other diseases It is inevitable that, on occasion during such treatment, indications will arise for surgical treatment of the primary or some intercurrent disease There still appears to be a widespread belief that administration of adrenocortical hormones adversely affects healing and resistance to infection It is the experience of this unit, however, that the administration of moderate doses of these hormones adds no danger to the operation concerned and carries no additional risk of complications Our findings agree with many recent reports that most surgical wounds heal normally during continuous treatment with adrenocortical hormones

Material

We have records of 19 patients who have undergone thirty-six surgical operations while under treatment with adrenocortical hormones We are not concerned here with the indications for treatment with these hormones or with side-effects other than those bearing on the response to surgery The accompanying table gives the details The cases are divided into groups according to whether the operation was elective or emergency, and clean or septic Since 9 of the 19 patients had more than one operation, we have numbered both the patients and their operations

All the patients had chronic rheumatoid arthritis except case 2 (ankylosing spondylitis), case 3 (disseminated lupus erythematosus), case 18 (polyarteritis nodosa), and case 12 (breast cancer)

Dosage

Immediately before operation all the patients were receiving oral cortisone or an analogue or corticotrophin sufficient to suppress at least partly the symptoms of their disease The preparations given are listed in the table in the order in which they were used, the one being taken at the time of operation being the last mentioned Steroid therapy was continued over the period of operation in all but 1 case, and it has been our routine to give additional cortisone to patients receiving this drug or an analogue The table shows that most of the operations for which no additional cortisone was given were minor The precise schedule of this additional dosage varied somewhat, usually, for operations not involving the gastro-intestinal tract, 75–100 mg of cortisone acetate was given intramuscularly twenty-four hours and one hour preoperatively, or a single injection of 150 mg an hour preoperatively, oral administration being continued until the time of operation and resumed as soon as possible afterwards For partial gastrectomy 100–150 mg of cortisone was given intramuscularly twenty-four hours and one hour preoperatively and a further 100 mg twelve hours postoperatively intramuscular administration was continued for the next three days, with a daily dosage of 100, 100, and 75 mg, and oral administration was resumed on the fourth postoperative day

No dosage has been listed for the 7 patients receiving corticotrophin, because the variation in strength between the batches of corticotrophin at present available and the individual variation in responsiveness make the nominal dosage meaningless All these patients, however, showed clinical evidence of suppression of their disease, and all 5 patients in whom the urinary excretion of 17-hydroxy corticosteroids (Appleby et al 1955) was estimated showed evidence of adrenal stimulation, corticotrophin was continued over the operation, but no additional dose was given The management of patients receiving corticotrophin is discussed below

Complications

In twenty-six of the thirty-six operations the postoperative course and wound healing were normal Cases 5, 6 (operation 1), and 8 (operation 2) developed slight superficial wound infections, which responded rapidly to treatment and did not significantly affect healing, and case 9 had a hæmatoma

Serious complications occurred in cases 3, 13, and 14 (see below)

Discussion

Side-effects

Some of the earlier published reports (Ragan et al 1949, Baker and Whitaker 1950, Baxter et al 1951) emphasised the possibility of side-effects of corticosteroid therapy Among these several are important in surgery, notably defective healing of wounds and bone, impaired resistance to infection, modification of the clinical picture of the acute surgical condition, and suppression of normal pituitary-adrenal responses

These reports were based on experiments on animals given a relatively large dosage They have undoubtedly

* Cortisone was stopped on day of operation and for several weeks afterwards

† For dosage in cases treated with corticotrophin see text

influenced the attitude of many surgeons towards operating during treatment with adrenocortical hormones, although it was also shown that, if doses of the order usually given therapeutically were administered to animals, there was little evidence of these side-effects (Cole et al 1951) Some aspects of our own experience are discussed here in the light of these experimental findings

Healing

Thorn et al (1954) state that serious interference with wound healing is rare unless the dosage is large (more than 150 mg of cortisone daily) and prolonged and protein intake inadequate

Wound healing was normal in 17 of our 19 patients , the 2 exceptions were receiving corticotrophin and showed evidence of excessive adrenal stimulation at the time of operation

Case 3 —At the time of her first operation for pinning of spontaneously fractured neck of femur the patient presented many of the features of Cushing's syndrome, and her daily excretion of 17-hydroxycorticosteroids was high , in spite of this her wound healed normally, although the fracture did not unite When the pin was removed nine weeks later, she showed less evidence of hyperadrenalism, but wound healing was delayed Healing was again delayed after her third operation, when prednisolone 15 mg daily had been substituted for the corticotrophin, but she was found to be anæmic, and, once the anæmia had been corrected, healing was rapid , the slow healing after the second operation was also probably due partly to anæmia

Case 14 had a burst abdomen four days after partial gastrectomy His mean urinary excretion of 17-hydroxycorticosteroids over this period was 40 mg daily, and it is therefore likely that the defective wound healing was related to the excessive production of corticosteroids

Operations on bone were followed by normal healing in all except case 3 Three arthrodeses and a bilateral cup arthroplasty of the hip-joints were completely successful, and clinical and radiological evidence of sound union was obtained within the expected time

Individual variation in susceptibility to the various effects of the hormones appears to be considerable One can judge more accurately whether healing is likely to be delayed by inspection of the patient than by consideration of the dosage of hormones given This clinical approach can be reduced to simple terms

(1) Patients who appear normal will heal normally

(2) Patients who show the features of Cushing's syndrome may heal badly

(3) Patients who have definite rounding of the face but only slight other side-effects will probably heal normally, unless

(4) they also have anæmia, severe wasting, or gross abnormality of the plasma-protein levels, when they may heal badly

Surgery in Peptic Ulceration

It is generally agreed that the incidence of peptic ulcers increases in patients receiving adrenocortical hormones orally, and that the risks of perforation and of hæmorrhage are also somewhat increased However, it has been reported that ulcers healed with medical treatment although the administration of adrenocortical hormones was continued (Bollet et al 1955), and we also have observed this

In our experience surgical treatment can equally well be undertaken while treatment with adrenocortical hormones is continued, with confidence that healing of intestinal anastomoses will be normal

4 of our patients underwent operations for chronic peptic ulceration (partial gastrectomy 3 cases , vagotomy and gastroenterostomy 1 case) , in all the cases the postoperative course was uneventful and recovery rapid The end-results of these operations were uniformly satisfactory, and adrenocortical hormone treatment has been continued successfully

6 other patients required emergency surgery for complications 3 for perforation and 3 for hæmatemesis Cases 1, 11, and 15 all had the classical symptoms and signs of acute perforated peptic ulcer , none was much shocked, all were operated on early, and all made rapid recoveries, though 2 later had to have more radical surgery

3 patients had massive bleeding case 8 recovered quickly and well from emergency partial gastrectomy , but cases 13 and 14 died Both the patients who died presented gross clinical evidence of hormone overdosage, whereas case 8 did not Case 13 appeared to be in good general condition despite massive and repeated hæmorrhage, and he might have been saved if he had been operated on before he became severely shocked

Case 14 died from a succession of gastrointestinal hæmorrhages caused by widespread oozing from a thin friable mucosa For many days, in spite of almost continual hæmorrhage, his general condition seemed good , any patient not receiving adrenocortical hormones who endured such a severe series of hæmorrhages would probably have appeared more ill and would have been submitted to surgery sooner than this patient was As it happened, little could be done surgically to arrest the bleeding

Although these patients presented the classical signs of perforation or of hæmorrhage, their general appearance belied the severity of the condition , this may lead to dangerous delay in undertaking appropriate surgical treatment We therefore suggest that surgery should be considered earlier for patients under treatment with corticosteroids than the usual criteria would indicate

Surgery and Bacterial Infection

The earlier views of the dangers of corticosteroid therapy in the presence of infection have been considerably revised It is now accepted practice to use the hormones in combination with antibiotics in treating certain infections There is still reluctance to operate on an infected focus while these hormones are being given, but in 5 instances where operation was done in a septic field no unusual measures were needed, and resolution was rapid and uneventful

Case 18 had suppurative otitis media which repeated courses of antibiotics did not cure Operation was delayed for several weeks because the patient was receiving prednisolone, but after radical mastoidectomy the discharge ceased and the wound healed quickly by first intention

Case 17 had chronic suppurative maxillary sinusitis which had resisted repeated lavage Bilateral nasal antrostomy led to rapid resolution although treatment with corticotrophin was continued, and the infection has not recurred ten months after operation

Case 19 had severe orbital cellulitis with suppuration Drainage of the abscess, penicillin, and anticoagulants led to complete recovery within three weeks , treatment with corticotrophin was not interrupted

Case 11 had extensive dental caries and pyorrhœa Dental clearance was done in two stages under penicillin cover, and healing was rapid and complete At this time she was receiving prednisone 20 mg daily

Pituitary-adrenocortical Suppression

Acute stress, such as a surgical operation, in some way stimulates secretion of corticotrophin by the pituitary gland, and this in turn leads to increased secretion of adrenocortical hormones But therapeutic administration of these hormones inhibits the normal mechanism , and, after such treatment has been discontinued, pituitary and adrenocortical functions remain impaired for days and occasionally many months (Salassa et al 1953b) During this period the response to stress is subnormal, and any severe stress may cause death from acute adrenocortical insufficiency Death or severe shock from this cause has been reported by Fraser et al (1952), Salassa et al (1953a), Lundy (1953), Robinson et al (1953), Harnagel and Kramer (1955), Downs and Cooper (1955), Richman et al (1956), Hayes and Kushlan (1956), Allanby (1957), and Slaney and Brooke (1957)

It is therefore imperative that the administration of adrenocortical hormones be continued throughout the operation and postoperative period If the operation is more than minor, a larger dosage of hormones must be given to allow for the increased requirement which the patient's own pituitary-adrenal system will not supply This additional dosage can conveniently be given in the form of one or two intramuscular injections of cortisone, because absorption by this route is slow, and the maximal effect may not be reached before twelve hours For the same reason intramuscular cortisone alone cannot be relied on for the treatment of acute adrenocortical insufficiency during or after operation, should this arise, hydrocortisone in addition should be administered intravenously by continuous drip

The management of patients receiving corticotrophin is more difficult The great variation in individual response and in the potency of different preparations and batches of corticotrophin makes any system of nominal dosage meaningless Treatment can be controlled satisfactorily only if the urinary excretion of 17-hydroxycorticosteroids is measured regularly, as an index of the amount of adrenal stimulation Our practice has been to continue giving corticotrophin over the period of operation and to base any alteration of dosage on the daily excretion of 17-hydroxycorticosteroids As with the patients having oral hormones, hydrocortisone can be given intravenously if signs of acute adrenocortical insufficiency develop

Conclusions

Operations during long-term treatment with adrenocortical hormones *carry no increased risk of complications*, provided that there are no gross signs of overdosage with the hormones, and the administration of the hormones is not interrupted

Summary

Thirty-six operations done during treatment with either adrenocortical hormones or corticotrophin are reviewed

Wound healing was uneventful after thirty-three of these operations

Bone repair was normal apart from non-union of a fractured neck of a femur

2 patients died and 1 recovered after gastrectomy for gastrointestinal hæmorrhage

Three elective operations for peptic ulceration and three emergency operations for perforation were uneventful

Five operations in the presence of sepsis were uneventful

Postoperative complications were insignificant

Except in 1 case hormone treatment was continued throughout the operation and postoperative period

This work has been aided by grants from the Dan Mason Research Foundation of the West London Hospital Medical School and the Empire Rheumatism Council We wish to thank Dr W S C Copeman for permission to report these cases, Mr A L Walker, Mr G F G Batchelor, Mr H W Burge, Mr J C R Hindenach, Mr K G Rotter, and Mr G B Woodd-Walker, by whom most of the operations were done, Mr G N Golden, Mr W J Ferguson, Mr R A V Lewys-Lloyd, and Mr V J Downie for information about patients on whom they operated, *Dr Oswald Savage* and Dr H M Lloyd for encouragement and advice, and Dr Leslie Chapman for the steroid estimations

A HOLZEL
M D Prague, D C H
SENIOR LECTURER IN CHILD HEALTH

G M KOMROWER
M B Manc, F R C P
LECTURER IN CHILD HEALTH

IN THE UNIVERSITY OF MANCHESTER

HITHERTO the incapacity of some infants to metabolise galactose normally has not been discovered until signs and symptoms of galactosæmia have been produced by ingestion of milk The clinical syndrome, which is probably due to disturbance of normal carbohydrate metabolism consequent on an accumulation of galactose-1-phosphate in the tissues (Schwarz, Golberg, Komrower, and Holzel 1956) could be avoided if the child's abnormality were recognised before any milk was given

We report here a method of recognising the abnormality soon after birth The test is made on cord blood, and thus involves no risk or inconvenience to the baby The reagents and equipment used are readily available in hospital laboratories

Principle

The method is based on the observation that incubation of galactosæmic erythrocytes with galactose leads to accumulation of galactose-1-phosphate in the cells The amount of galactose-1-phosphate which accumulates in normal erythrocytes in such circumstances is much smaller

The erythrocytes are incubated first with galactose and then with glucose, the free sugar is washed out with saline solution, after removal of protein the total organic and inorganic phosphates are precipitated as barium salts, and the galactose- and glucose-1-phosphates are selectively hydrolysed to free galactose and glucose These sugars are then separated chromatographically, and the amount of galactose is estimated by comparison with known quantities chromatographed simultaneously

Method

Heparinised cord blood, within 1–2 hours of collection, is introduced in a siliconed graduated 15 ml centrifuge tube up to the 2 ml mark Another sample is taken for determination of the hæmatocrit A solution of 2% galactose in saline solution (0 02 ml) is added, the tube is stoppered, and the contents are mixed The blood is incubated at 37°C for 2 hours with occasional mixing Ice-cold saline solution is then added to about 12 ml and, after mixing, the cells are spun down at medium speed, and the supernatant fluid is removed The washing is repeated twice with 12 ml of saline The cells are then reincubated with occasional mixing for 2 hours at 37°C with 0 1 ml of 2% glucose in saline and enough saline to give a volume of 2 ml The cells are washed three times with 12 ml of saline to remove free glucose

The cells are lysed by shaking with 2 vols of water containing a little saponin, and freezing Ice-cold 20% trichloracetic acid (3 vols.) is added, and the mixture is kept in ice for 6 minutes with occasional hard shaking After the mixture has been centrifuged in ice-cold buckets for 2 minutes, its total volume is recorded, and it is poured through a sintered-glass filter To the filtrate, whose volume is measured, 2 drops of 25% barium acetate is added, followed by a slight excess of 40% NaOH (phenolphthalein being used as the indicator) It is important to carry out these last operations quickly and to keep the mixture cold while the pH is acid, since the galactose-1-phosphate is readily hydrolysed in acid solution The phosphates are precipitated quantitatively by the addition of 4 vols of ethanol and by being kept in the refrigerator at least one hour (or overnight)

The precipitate is spun down, the supernatant removed, and the precipitate washed once with 5 ml of-neutralised ethanol After addition of 1 5 ml of water the precipitate is broken up with a glass rod, and the mixture is neutralised to phenolphthalein with *N* HCl and then made 0 1 *N* acid by the addition of 0 1 vol of *N* HCl The phosphates are hydrolysed by immersion of the mixture in boiling water for 7 minutes

After cooling, about 0 5 ml of water is added, followed by a slight excess of *N* H_2SO_4 to precipitate the barium The mixture is neutralised with 2*N* NH_4OH and centrifuged The supernatant fluid is transferred to a small evaporating-cup, made by cutting off a test-tube of 1 5 cm diameter about 2 cm from the bottom The precipitate is washed twice with 0 2 ml of water, and the washings are transferred to the cup The solution, which contains the free galactose and glucose derived from easily hydrolysable phosphates, together with some other components, as well as ammonium sulphate and chloride, is evaporated to dryness in a vacuum desiccator over $CaCl_2$

The dry residue is allowed to absorb some moisture from the atmosphere to facilitate grinding This is done with a small glass rod with an enlarged rounded end in the presence of 0 1 ml of pyridine, which extracts the free sugars After thorough grinding, the "slurry" is transferred with a pasteur pipette to a hæmatocrit tube The residue in the cup is ground twice, with each time 0 06 ml of pyridine, to complete the extraction and to transfer the "slurry" to the tube After the contents have been mixed by shaking up and down the tube several times, the solids are sedimented by sharp centrifugation for 4 or 5 minutes

The height of the liquid column, excluding the sediment, is noted, and half is transferred with a capillary tube to the starting-line of a descending chromatogram This is run on a sheet of no 4 Whatman paper, 58 cm long, with a 10 cm long folded strip of paper stapled to the bottom Known amounts of galactose (5, 10, 20, and 30 μg) are placed alongside the sample Without prior equilibration the chromatogram is run overnight in *n*-butanol/pyridine/water (30/20/15 by vol) (Jeanes et al 1951) After drying in a current of cold air the chromatogram is dipped in freshly prepared benzidine reagent (0 5 g of decolorised benzidine in 5 ml of glacial acetic acid, 20 ml of acetone, 4 ml of 100% trichloracetic acid, and acetone to 100 ml , added in that order) (Harris and MacWilliam 1954) The chromatogram is heated for 2–4 minutes in an oven at 100°C until the paper begins to turn pale yellow

The amount of galactose in the sample is estimated visually by comparison with the known amounts, either in daylight or in ultra-violet rays, in which the spots exhibit a bright greenish yellow fluorescence From this the amount of galactose accumulating in 1 ml cells per 2 hours is calculated

The complete test can be carried out in 2–3 days but requires relatively little attention

Results

The cord blood of 18 normal babies and the venous blood of 2 babies with galactosæmia were examined by this method, with the following result

Normal blood (mean) 3 5 μg of galactose per c cm of red cells (range 0 7–9 8)		
Galactosæmic blood	case 1	58 μg of galactose per c.cm of red cells
	case 2	76 μg of galactose per c cm of red cells

Diagnosis of Galactosæmia in a Newborn

The cord blood of case 3, sib to case 2, was examined by the method described above In addition, a sample of this blood, without incubation with galactose, was analysed for galactose-1-phosphate to find out whether any galactose had accumulated in utero The results were

Galactose-incubated blood	108 μg	(±12) of galactose	per c.cm
Unincubated blood	35 μg	”	”
Hence accumulation of galactose-1-phosphate during incubation	73 μg	”	”

On the basis of this test a diagnosis of galactosæmia was made on the third day of life, in the absence of any clinical symptoms The baby, initially fed on glucose-saline solution, was put on the milk-free diet described by Holzel (1954), she weighs 11 lb 10 oz at the age of 17 weeks and is developing normally

Discussion

We have shown previously (Komrower, Schwarz, Holzel, and Golberg 1956) that a galactose-tolerance test may not be without danger to an infant suffering from congenital galactosæmia The laboratory test described here enables a diagnosis to be made without recourse to the galactose-tolerance test and in the absence of any clinical symptoms and signs of the disease, thus eliminating the possibility of interference in the physical and mental development due to the injurious effect of galactose

Obviously, the test cannot be applied to all newborn infants, so as to detect the sporadic case of galactosæmia , but it could be applied to every newborn infant with a family history suggestive of the disease

The margin between the behaviour of normal and galactosæmic erythrocytes is wide and should enable a firm diagnosis to be made on the basis of the described test

Our experience with case 3 shows that galactose-1-phosphate may accumulate in the tissues in utero, in spite of some restriction of milk intake by the mother during gestation No galactose was detected in the mother's venous blood on two occasions after the consumption of a pint of milk At parturition no galactose was found in the liquor amnii (less than 0 04 mg per 100 ml) We do not know whether the relatively small amount of galactose-1-phosphate present in the erythrocytes at birth is matched by a similar concentration in other tissues, but it is not unlikely that the liver may contain more Nor can we say at this stage whether such small concentrations are injurious

It is hoped that the institution of a milk-free diet from birth, as made possible by the new test, will prove to be of real benefit

We have found the new test, in a slightly modified form, useful for establishing the diagnosis of untreated cases (The modification consists in omitting the incubation of the cells with glucose or galactose) Thus a four-week-old baby, presenting with the usual symptoms, was found to have 210 μg galactose per c cm of red cells in the form of galactose-1-phosphate Since this phosphate disappears only very slowly from the cells, the diagnosis can be made even in the absence of galactose from the blood and urine

Summary

A diagnosis of congenital galactosæmia can be made, within 2–3 days of birth, by a test performed on cord blood The infant can be given, from the first, a galactose-free diet and can thus be saved from the damaging effect of extraneous galactose

The test is useful for establishing the diagnosis of untreated cases

A case is described in which the diagnosis was made in this way in a newborn infant Her erythrocytes contained galactose-1-phosphate at birth, which showed that some galactose had entered the tissues in utero, though it had not been detectable in the mother's blood

We wish to thank Dr K D Coorey for his cooperation in securing the samples of normal cord blood, and Miss I M N Simpson for her able technical assistance

TORSION OF THE STOMACH
AS A CAUSE OF VOMITING IN INFANCY

S Eek
M D
PÆDIATRIC RADIOLOGIST

H Hagelstein
M D
LECTURER IN PÆDIATRICS

UNIVERSITY HOSPITAL, OSLO, NORWAY

From the Children's Department, University Hospital, Oslo, Norway

Although an organic cause is evident in many cases of vomiting in infancy, many infants are still recorded as having neuropathic or habitual vomiting

From radiological examination of such patients we noticed for the first time, about five or six years ago, a characteristic shape and position of the stomach in some of the cases Since then we have found these characteristics with increasing frequency, and up to May 1, 1957, we had diagnosed this condition in 54 children (34 boys and 20 girls), ranging in age from one day to three years

The radiological findings are strikingly alike in all cases The body of the stomach is raised, with the greater curvature as the highest point and the lesser curvature as the lowest The posterior wall of the stomach points forward, and the pyloric antrum and pylorus with the duodenal bulb are directed more or less straight down The middle part of the transverse colon is interposed between the liver and the anterior abdominal wall and comes above and in front of the stomach, often even just under the diaphragm The following cases are illustrated in fig 1

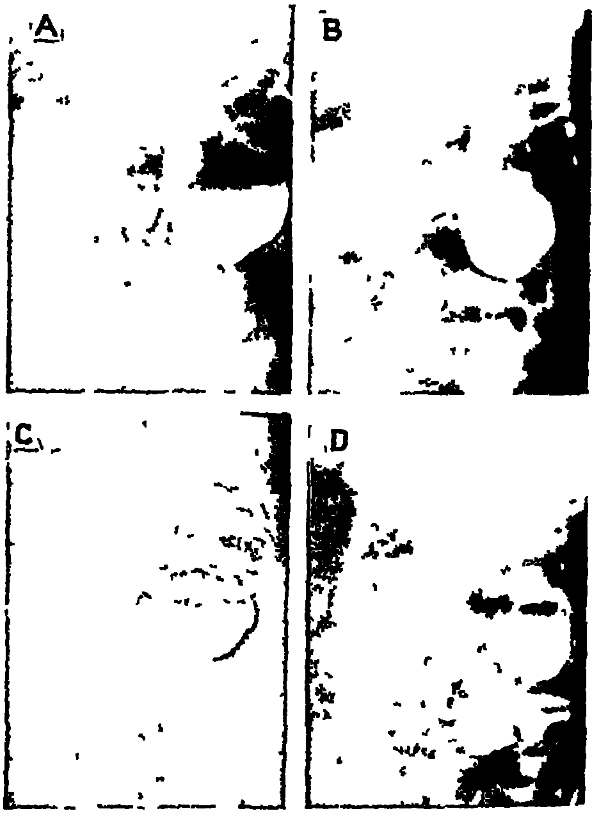

Fig 1—Findings in cases A–D See text

Case A—A girl, aged 6 weeks, with vomiting after feeds from the age of 2 weeks, never projectile Gained weight Immediate improvement when she was placed on her right side

Case B—A boy, aged $2^1/_2$ months, had from the age of 2 days uncharacteristic vomiting after practically all feeds Unsatisfactory gain of weight Vomiting ceased when he was placed on his right side

Case C—A boy, aged 4 weeks, had daily projectile vomiting from first day of life Gained weight Immediate improvement when he was placed on his right side

Case D—A girl, aged 3 weeks, had projectile vomiting from first day of life Loss of weight Immediate improvement when she was placed either prone or on her right side

Causation

Normally the stomach is fixed at two points—the cardia and the pylorus At the cardia it is fixed by the upper part of the hepatogastric ligament and by the gastrosplenic ligament At the pylorus the duodenum is fixed behind the peritoneum The rest of the stomach is suspended freely by the hepatogastric ligament The transverse colon is normally suspended below the greater curvature of the stomach by the thin and short gastrocolic ligament

In infants the lower thoracic aperture is relatively open and the liver easily mobile In the supine position the anterior edge of the liver descends,

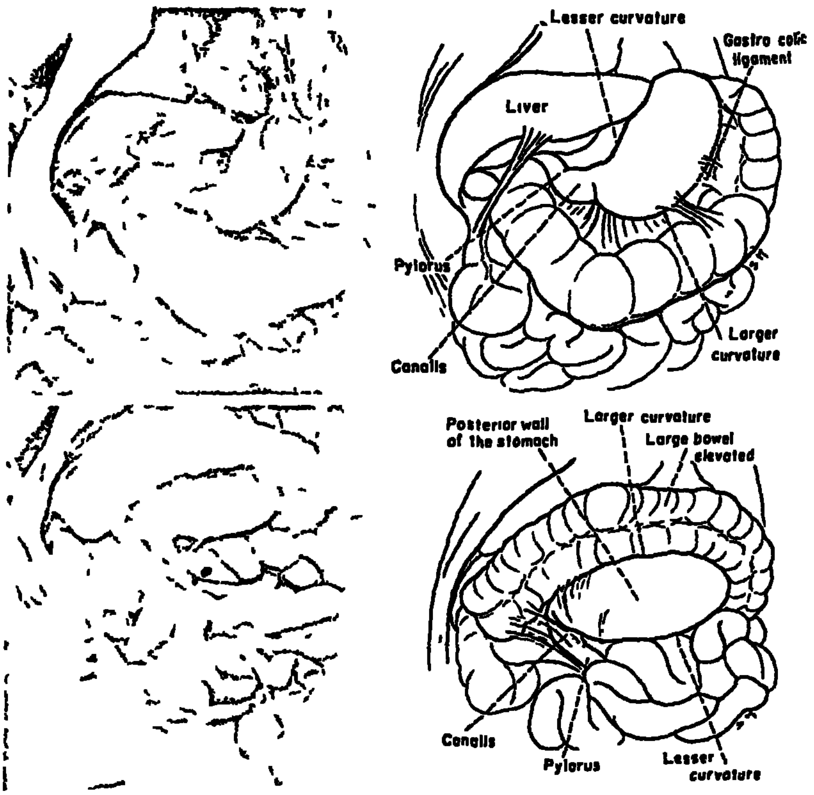

Fig 2—Artificial rotation of stomach post mortem

Above stomach and transverse colon in normal position but inflated with air Below air-filled transverse colon placed above and in front of stomach, rotating stomach through 180 and bringing posterior wall of stomach to point forwards, with greater curvature as highest point and lesser curvature as lowest point Pyloric antrum and pylorus with duodenal bulb is directed straight downwards exactly as in radiographs (fig 1)

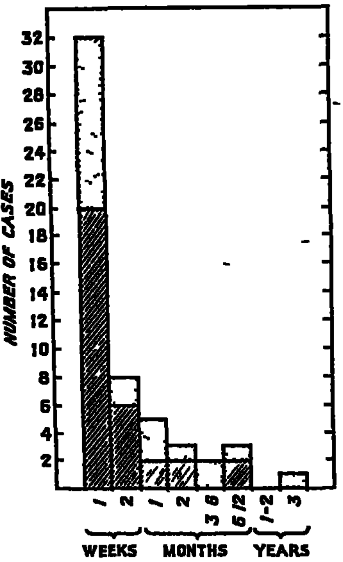

Fig 3—Age-incidence of onset of symptoms Hatched histograms, projectile vomiting

and a space may open between the liver and the anterior abdominal wall, into which a gas-filled transverse colon may easily rise In these circumstances the transverse colon pulls the stomach and twists it on its longitudinal axis with the cardia and pylorus as fixed points

This mechanism of twisting can be reproduced post mortem (fig 2) In our experience this twisting has never been more than 180° and it can be less The twisting may delay gastric emptying, interfere with peristalsis, and perhaps also disturb the circulation of the blood in the stomach

Symptoms

Vomiting beginning soon after birth is the main symptom (fig 3) Vomiting is often observed in the very first days after birth, but it may also begin later Our eldest patient was 3 years old The symptoms often start as gulps which increase to vomiting More than half the patients were observed to have projectile vomiting

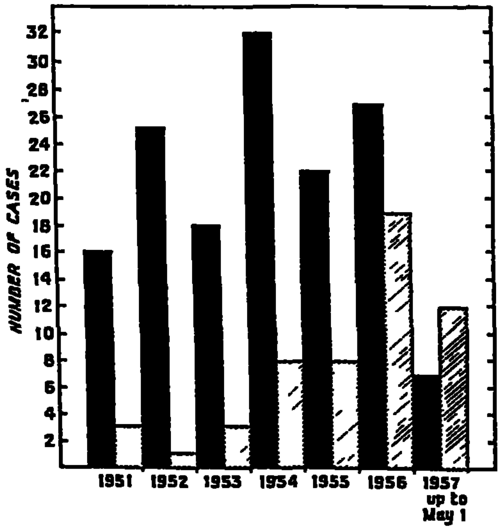

Fig 4—Incidence of twisting of stomach (hatched) and of congenital pyloric stenosis (black)

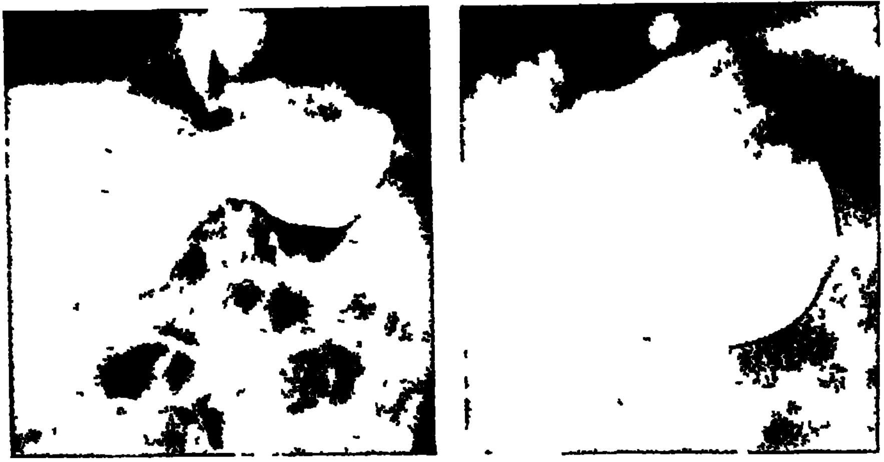

Fig 5—Stomach untwisted by holding baby head down Left before Right after

Vomiting did not always occur immediately after feeding, its force and frequency varied, but usually it occurred daily Of the 54 patients 18 gained weight satisfactorily in spite of daily vomiting, 21 gained little or no weight, and 15 lost weight

Patients with twisting of the stomach usually do not present so serious a clinical picture as infants with congenital pyloric stenosis, but it is often impossible to distinguish clinically between the two conditions In twisting of the stomach a pyloric tumour, of course, cannot be palpated Of the 54 patients 43 had vomiting as the only symptom in the remaining 11 the child was admitted to hospital for some other condition such as eczema, congenital heart-disease, epilepsy, or cerebral palsy

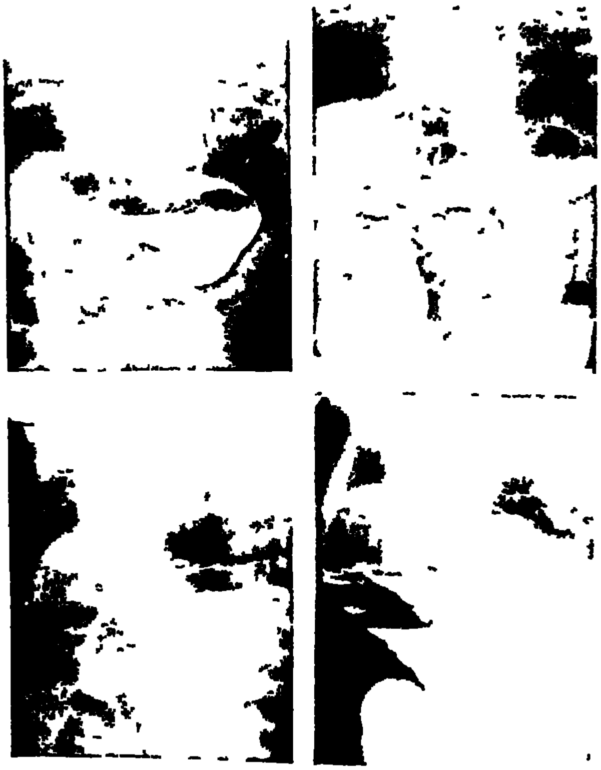

Fig 6—Unsuccessful attempt to untwist stomach by loading transverse colon with barium in a boy, aged 7 weeks Left before Right after Above left anterior oblique Below left lateral

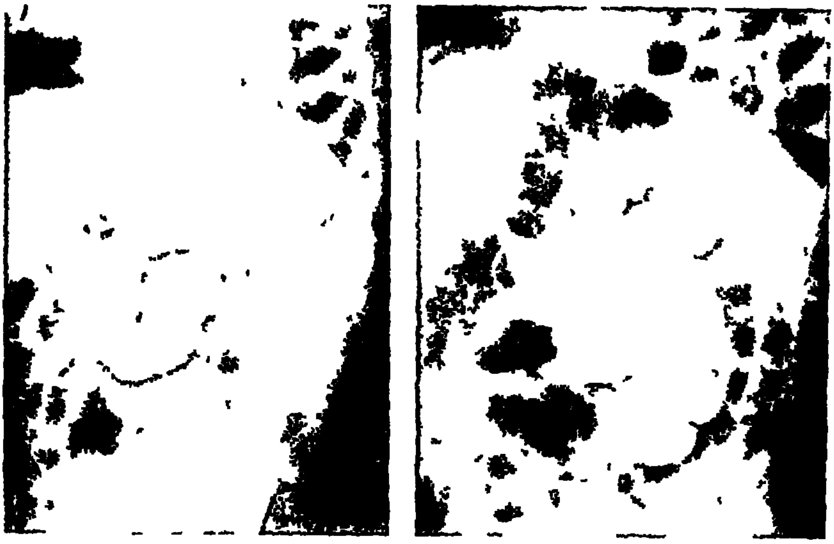

Fig 7—Twisting of stomach produced by inflation of transverse colon per rectum in a boy, aged 7 weeks, with increasing vomiting since age of 3 weeks

No projectile vomiting Unsatisfactory gain of weight. Immediate improvement when boy was placed on his right side Left stomach approximately in normal position before inflation of colon Right after inflation radiograph shows typical twisted stomach with transverse colon above it

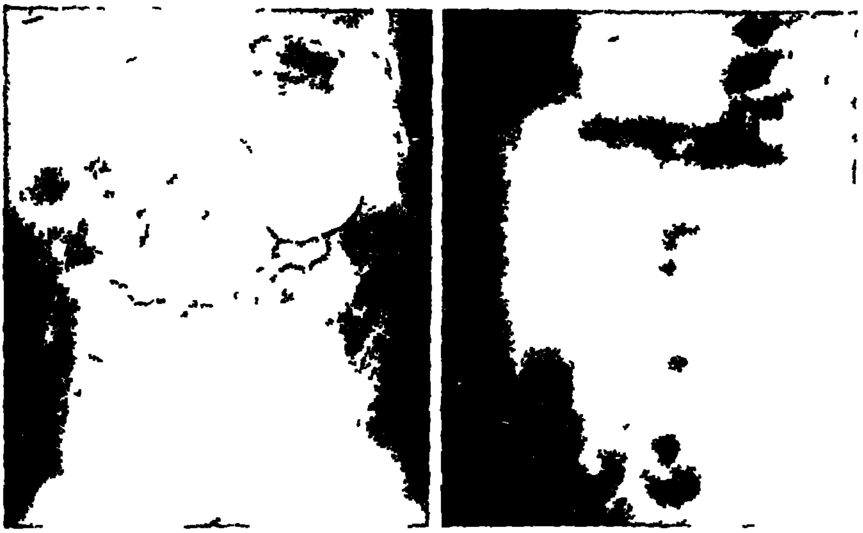

Fig 8—Intermittent twisting of stomach in a girl, aged 1 week, with vomiting from birth Left stomach normal in shape and position Right: typical twisted stomach three days later

Incidence

The condition is not rare In 1956 and the first four months of 1957 it was diagnosed in about the same number of cases as congenital pyloric stenosis (fig 4) The greater number of cases found in recent years is due to the care with which we have sought it We have not accepted clinical diagnoses such as habitual vomiting, nervous vomiting, and rumination, and every case of vomiting has been radiologically examined

X-ray Examination

Torsion is best displayed when the patient is examined in the erect position He is placed in a special cotton garment, suspended by four straps, which at the same time hold the head erect

The degree of twisting depends on the position of the transverse colon As stated, it has never exceeded 180°

We have tried to untwist the stomach by holding the patient head down to induce the transverse colon to move towards the pelvis This has only rarely been successful, as in the following case

Case E —A boy, aged 6 weeks, had vomited from the age of 2 weeks No projectile vomiting Satisfactory gain of weight. Did not vomit when placed on his right side Typical radiograph. When he was held head down, the stomach regained a normal position (fig 5)

We have also tried to untwist the stomach by filling the colon with barium, hoping that the weight of the barium might bring the transverse colon back into its normal position These attempts failed (fig 6)

In one case in which torsion was suspected the stomach appeared to be in its normal position on radiography, but we *confirmed* the diagnosis by *inflating* the transverse colon per rectum and thus twisting the stomach (fig 7) This goes to show that torsion of the stomach may sometimes be intermittent, therefore normal appearances on radiography are not conclusive, and the typical shape and position of the twisted stomach may be found at a subsequent examination (fig 8)

Treatment

The treatment is very simple The patient should be *placed* prone, with the upper part of his body lowered, or alternatively merely placed on his right side. Usually vomiting will cease immediately or become noticeably less In a few cases the vomiting may continue for some time In no case has it been necessary to untwist the stomach surgically

Comment

Since we became interested in this condition we have diligently tried to find references to it Torsion of the stomach in adults is well known (Dalgaard 1952), but the only mention of it in infants appears to be by Roviralta (1949), who called it "la plicature de la grande courbure de l'estomac" He made no mention of the cause

Summary

Torsion of the stomach is common in infants

A collection of gas raises the transverse colon to a position between the liver and the anterior abdominal wall , and the colon, being attached to the greater curvature of the stomach through the gastrocolic ligament, twists the stomach forwards and upwards

The chief symptom is vomiting, sometimes projectile, and usually beginning soon after birth

Treatment is simple the baby is placed either prone or on its right side

A NOTE ON THE RELATION OF APPETITE TO EXERCISE

R PASSMORE
M A , D M. Oxon
READER IN CLINICAL AND INDUSTRIAL PHYSIOLOGY, THE DEPARTMENT OF PHYSIOLOGY, UNIVERSITY OF EDINBURGH

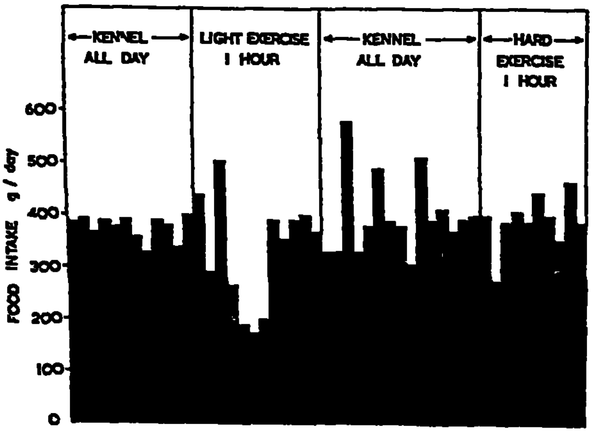
MEDICAL writers often discount the value of exercise in the treatment of obesity, because it is alleged that the extra physical activity will promote appetite, and the energy value of the extra food consumed will be the same as, or even more than, the energy value of the exercise There is, of course, no doubt that in physically active persons appetite balances, with remarkable precision, the energy values of the food eaten and the work performed But this may not be so in sedentary people

Mayer et al (1954) showed that when rats were made to walk on a treadmill for periods ranging from 1 to 6 hours daily, food intake was related to the duration of exercise and their weight was maintained constant If, however, exercise was restricted to less than an hour, there was no corresponding fall in food intake Indeed, more, not less food was eaten, and the animals gained weight I have long thought about ways and means of repeating this elegant experiment on man, but the psychological difficulties appear insuperable Recently, however, an opportunity arose to repeat their observation on a dog, which had become moderately obese during a period when it was kept in the animal-house and had free access to a liberal mixed diet

This dog was put on a diet consisting of equal parts of brown bread and a proprietary preparation of dog meat, minced together A weighed amount of food was put in the kennel each day at about noon, and removed as soon as the dog had finished eating The residue of food was then weighed This regime was continued for 49 days

During days 1–12 and 25–39 the dog remained in the kennel throughout On days 13–24 it had an hour's light exercise (walking on a treadmill on the level at 3 5 m p h), and on days 40–49 it had an hour's hard exercise (walking on a treadmill at 3 5 m p h up an incline of 1 in 10) The dog readily accomplished this and was not exhausted at the end

The figure shows that on some days when light exercise was taken the food intake was reduced, and that throughout the period of hard exercise, it was the same as in the two sedentary periods Average daily food consumption was 378 g during the first sedentary period, 331 g during the period of light exercise, 396 g during the second sedentary period, and 391 g during the period of hard exercise



There was a slight loss of weight during the sedentary periods (attributable perhaps to the limited access to food) but this loss was increased by the exercise, and over the whole period the weight fell from 25 0 to 22 6 kg The dog was very fit at the end of the studies

In this animal, clearly, a short period of exercise did not increase the appetite above the sedentary level The result is thus in line with the study of Mayer et al , and supports their suggestion that a certain minimal level of physical activity is necessary for the appetite to function with precision and to adjust food intake to requirements

If this hypothesis can be substantiated in man, it has great practical importance in the treatment of obesity It is not generally realised how sedentary is the life led by most urban people Even young military cadets spend 17³/₄ hours a day either lying, sitting, or standing (Edholm et al 1955) , the corresponding figure for coalminers is 18³/₄ hours a day and for colliery clerks 20 hours a day (Garry et al 1955) Military cadets and miners have two of the most physically active occupations, and yet about three-quarters of their life is sedentary The daily physical activity of many thousands of light workers (and housewives may be so defined—see Durnin et al 1957) may be below the threshold needed for appetite to function normally For this reason they may overeat and become obese If this is so, then perhaps the first duty of their physician is to prescribe a suitable regime of physical activities

I am indebted to the Medical Research Council for an expense grant

Preliminary Communication

AN ANTIBODY TO CASTLE'S INTRINSIC FACTOR

WE have succeeded in producing antibodies to preparations of human and pig intrinsic factor (I F) as the initial part of a scheme to demonstrate the site of secretion of I F

Three antigens have been used One was made from human gastric mucosa (substance E of O'Brien, Taylor, Turnbull, and Witts [1]) and the other two were partially purified preparations of pig pylorus, designated I F 1345 and I F II B2 In each case the antigen was dissolved in water and emulsified with a light paraffin oil, ' Bayol F ' (Esso Standard Oil Co), containing killed human *Mycobacterium tuberculosis*, and an emulsifying agent, ' Arlacel A ' (Atlas Power Co , Wilmington, U S A) Rabbits were injected with one of the three mixtures by multiple subcutaneous puncture This Freund adjuvant technique [2] was used because it is known to give high titres of antibody, which persist for long periods

Simple precipitation tests, using all three antigens and antisera, gave heavy precipitates from interaction of the human I F and the corresponding antiserum Both pig preparations and their corresponding antisera behaved similarly There was also some cross-reaction between I F 1345 and the rabbit anti-human-I F serum Results with the Ouchterlony

INHIBITION OF INTRINSIC-FACTOR ACTIVITY BY ANTISERA

Patient no	Preparation given	Percentage absorbed of 0 5 µg dose of ^{60}Co-labelled vitamin B_{12}
1	Vitamin B_{12} alone	5 2
	" " with 20 mg I F II B2	44·4
	" " with 20 mg I F II B2 + 20 ml normal rabbit serum	47 7
	" " with 30 mg I F II B2 + 20 ml anti-pig-I F serum	
	(*a*) supernatant	21 2
	(*b*) precipitate	7 2
2	Vitamin B_{12} alone	12 6
	" " with 20 mg I F II B2 + 20 ml normal rabbit serum	55 9
	" " with 20 mg I F II B2 + 20 ml anti-I F serum	
	(*a*) supernatant	0 0
	(*b*) precipitate	9 8
3	Vitamin B_{12} alone	18·0
	" " with 10 mg I F II B2	52 1
	" " with 20 mg I F II B2 + 20 ml normal rabbit serum	63 5
	" " with 20 mg I F II B2 + 20 ml anti-pig-I F serum	
	(*a*) supernatant	5 8
	(*b*) precipitate	37 3
4	Vitamin B_{12} alone	27 3
	" " with 26 mg substance E	60 4
	" " with 26 mg substance E + 20 ml anti-human-I F rabbit serum	2 9
5	Vitamin B_{12} alone	26 6
	" " with 26 mg substance E + 20 ml normal rabbit serum	39 3
	" " with 26 mg substance E + 20 ml anti-pig-I F rabbit serum	0 0

technique,[3] in which solutions of the antigen and antiserum are allowed to diffuse towards each other from cups cut in 1% agar in petri dishes, have suggested that in the case of I F 1345 the antigen consisted of more than one constituent Substance E gave only one band with its antiserum, but this was a very weak one and cannot be taken as conclusive evidence of homogeneity

None of the antigens used was pure I F, and the only means of determining whether antibody to I F was present in the antisera was by specific neutralisation of I F activity

I F activity was estimated by the fæcal excretion method of Heinle et al [4] in patients with pernicious anæmia controlled by treatment Amounts of I F known to possess demonstrable activity were dissolved in water and mixed with antiserum in the proportions suggested by previous precipitation tests The mixture, or the precipitate and supernatant separately, was administered with the test dose of ^{60}Co-labelled vitamin B_{12} Controls were done in the same manner, using normal rabbit serum I F activity could not be tested in the case of I F 1345 by the fæcal excretion method, since it already contained a relatively large amount of vitamin B_{12}

The results are shown in the table It can be seen that human and pig I F activity can be inhibited by specific rabbit antisera

Unless some means of splitting the antigen-antibody complexes differentially can be found, serological techniques are not likely to offer a possible method of I F purification, but, using the Ouchterlony plate method, they may provide a useful means of testing the homogeneity of I F preparations and add to the established criteria of purity

It is interesting that the rabbit is able to produce an antibody to I F It may be that I F is essentially an external secretion and causes sensitisation when it is introduced parenterally, or it may be that I F is partly or wholly species-specific Schwartz et al following up their original observation that patients with pernicious anæmia may become resistant to orally administered I F,[5] have recently [6] suggested that this phenomenon may be due to such sensitisation

New Inventions

A PLEURAL-BIOPSY PUNCH

THIS instrument enables a biopsy specimen to be taken from the parietal pleura, when an effusion is aspirated, without risk of damage to the lung It is large enough to take a satisfactory specimen (4 mm in external diameter) without causing more discomfort than ordinary aspiration under local anæsthesia Because the biopsy is clean-cut, the histological picture is undistorted

Fig 1 shows all the features of the punch except the stylet It consists essentially of two concentric tubes The short trocar point is sharp enough to penetrate the chest wall after a tiny incision has been made in the skin, but it does not puncture the lung if the effusion is completely aspirated Behind the point is a deep notch in the outer tube, which can be closed by twisting the back hexagonal grip clockwise, so sliding the pin on the base of the inner tube along the oblique slot in the base of the outer tube and advancing a sharp-cutting cylinder just past the notch with a rotary movement, thus cutting off and holding any tissue engaged therein In fig 1 the notch is seen half-closed A spring clip holds the pin in either the open or the closed position sufficiently firmly to prevent inadvertent movement

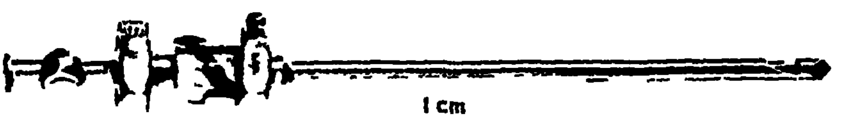

Fig 1—Pleural-biopsy punch with notch half-closed

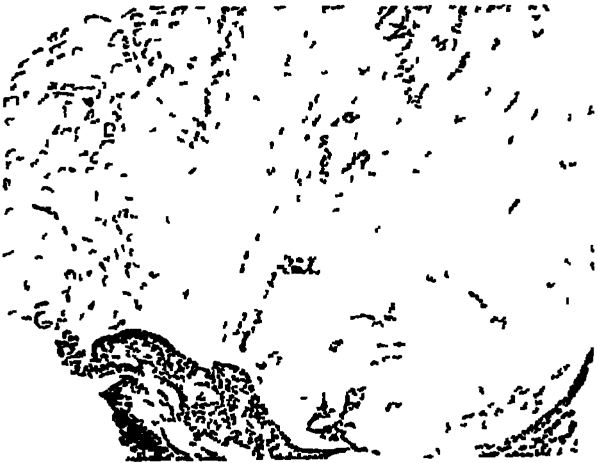

Fig 2—Pleural biopsy specimen showing intercostal muscle and thickened pleura infiltrated by carcinoma

Any type of syringe mount may be specified, so the punch can be used with apparatus for routine aspiration The two tubes can be completely separated for cleaning, and as all the parts are either stainless or heavily plated, they can be sterilised by boiling

Technique — The chest wall is infiltrated with local anæsthetic in the usual way, a tiny incision is made in the skin, and the punch is introduced with the notch closed, in which state it is airtight. The aspiration apparatus is then attached to the mount on the inner tube, the back hexagonal grip is twisted anticlockwise to open the notch, and the aspiration carried out. At the end of aspiration the notch is directed along the intercostal space by means of the indicator knob on the front hexagonal grip, the punch is slowly withdrawn, and sideways pressure in the direction of the notch is maintained until it is felt to engage in the chest wall The punch is then held firmly against the chest wall, the back hexagonal grip twisted sharply clockwise, and the punch withdrawn Finger pressure for two or three minutes stops any bleeding from the puncture The biopsy specimen is found either in the hollow point or inside the cutting cylinder

I have used the punch mostly as an aid in the diagnosis of pleural effusion of unknown origin in middle-aged patients

Fig 2 shows a biopsy specimen from a man, aged 56, who became very breathless in three weeks A very large yellow pleural effusion was aspirated several times After complete aspiration radiographs of his chest, bronchoscopy and bronchography failed to reveal the cause. Pleural biopsy was done with the next aspiration and showed thickened pleura infiltrated by carcinoma

I have also used the punch to obtain biopsy specimens from lung tumours in which there was good radiological evidence of adhesion of the lung The punch will take a biopsy specimen from any tissue into which it is inserted

Mestitz et al (1957) have related their experience with this punch, mostly in the diagnosis of tuberculous effusions In their series there were no serious complications in 116 biopsies I have had no complications in 30 biopsies

My thanks are due to Mr Holmes Sellors for his encouragement, and to all the consultant staff at Harefield Hospital, to Mr A L d'Abreu and Dr A Brian Taylor for allowing me to take biopsy specimens from their patients, and to Mr T F Dee for the photographs The Genito Urinary Manufacturing Company, 28a, Devonshire Street, London, W 1, made the instrument

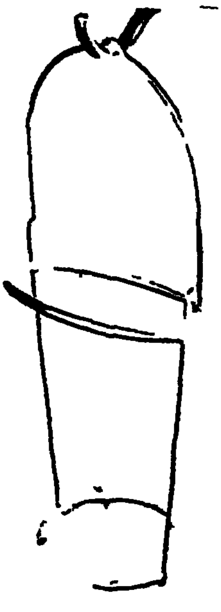
THE BRISTOL TRANSFUSION CRADLE

THIS cradle was designed to make transfusion-bottle changing an easier task, the frail wire clips supplied with transfusion sets are both awkward to fasten and unreliable when used for the second bottle



The cradle (see figure) contains two rings supported by cross-pieces with a loop for attachment to the transfusion stand The upper elliptical ring is set at an angle so that, after the upper part of the bottle has been passed through it, the bottle can rotate about a horizontal axis, its neck passing through a gap of $1^5/_8$ in in the lower ring

Cradles of this type have been in constant use for the past eight months and were found to save much labour

We are indebted to Mr A E Christmas, instrument maker at the Bristol Royal Infirmary, for assisting in the design, and Mr R. Bennett for making the trial prototypes The cradle can be obtained from Messrs Charles F Thackray Ltd, Park St, Leeds, 1

Reviews of Books

Essentials of Chemical Pathology

D N BARON, M.D, reader in chemical pathology, Royal Free Hospital School of Medicine, London London English Universities Press 1957 Pp 247 25s

IN twenty years the subject of chemical pathology has advanced from a sideline of clinical pathology to a major specialty in its own right, influencing the development of almost every field of medicine. These broad advances have been paralleled by a literature which at present consists mainly of advanced treatises or students' elementary textbooks Dr Baron has intended his book to provide medical students, housemen, and registrars with an adequate knowledge of chemical pathology to permit them to keep up to date with this ever-advancing subject.

The first part gives a general account of the normal and abnormal features of fluid and electrolyte distribution and of carbohydrate, fat, and protein metabolism There follow details of the applications of chemistry to the investigation of various systems The section on calcium, phosphorus, and bone, and those on water and electrolytes and on acidosis and alkalosis, are exceptionally good, but the kidneys could with advantage have been discussed more fully The chapter on the steroids is particularly useful, but a clearer account might have been given of the causes of difficulty in assessment of adrenal function. There is a remarkably complete account of differential estimations of serum-proteins, and such up-to-date topics as C-reactive protein, afibrinogenæmia, agammaglobulinæmia and fibrocystic disease are included

In an introduction, Sir Charles Dodds remarks that the author has refrained from quoting a large number of references, but the book covers so wide a field that many readers would welcome further reference to certain subjects

This is in no sense a laboratory manual, though some clinical procedures, as well as various methods for routine testing of urine, are described in detail It is perhaps a pity that Dr Baron's desire for completeness has led him to describe such out-of-date tests as Hay's test, the urea-concentration test, and the hippuric-acid tests, all of which are of little clinical value It is high time, too, that osazone and fermentation tests for the identification of glucose were abolished from chemical pathological practice, identification by paper chromatography or enzyme tests is more satisfactory

The statements that "The bilirubin which is originally produced from hæmoglobin is also called indirect, pre-hepatic or hæmobilirubin The modified bilirubin which has passed through the liver is called direct, post-hepatic, or chole-bilirubin" do not emphasise the need to drop this terminology The recent classification of the mechanism of the van den Bergh reaction by Lathe has led to the more logical use of the terms "bilirubin" and "conjugated bilirubin"

The book is perhaps too detailed for general use by the student, but it deserves to be widely read by the many doctors who nowadays seek the help of the laboratory of chemical pathology At 25s it is one of the best bargains among medical textbooks

Sigmund Freud Life and Work

Vol 3 The Last Phase, 1919-1939 ERNEST JONES, M.D, F R.C P London Hogarth Press 1957 Pp 536 35s

Dr Ernest Jones may rest content with his biographical labours Confronted with the peculiar difficulties that beset a psychoanalyst in this task, he has for the most part put aside the temptation to infer and to interpret. He has given us instead a well-documented and faithful story of the struggles and vicissitudes of Freud's life, it is a good historical account, which might have been written by someone quite incapable of making a subtle psychoanalytical dissection of what lay beneath the surface, in the way that Freud himself did in his essays on Goethe, Dostoevsky, and Leonardo

Half of the third and concluding volume is devoted to the last twenty years of Freud's life—a period of great physical suffering endured with noble stoicism, and of disappointments and upheavals which he met with unfailing humour and fortitude His character matched his intellectual power, and few who have read this biography will withhold admiration and respect, however little they may agree with the tenets of psychoanalysis In the account of this last phase, Freud's daughter Anna shines with a milder light in the background, a devoted and selfless helper The volume is appropriately dedicated to her

It is a pity that Dr Jones has given so much space to personal quarrels, such as that between himself and Rank It is clear that feuds among his followers distressed Freud and sometimes took up much of his time and thought, but the detailed account of suspicions and misunderstandings makes tedious reading

The latter half of the book consists of a review of Freud's contribution to a wide range of subjects, including religion, occultism, art, and literature This is naturally a subjective valuation, crediting Freud's work with a greater and more lasting impact than many who are expert in the respective subjects have been willing to concede It affords, however, a striking conspectus of the long creative activity of a fertile and very original mind

Chemotherapy and the Central Nervous System

HENRY MCILWAIN, PH D, D SC, professor of biochemistry, University of London, at the Institute of Psychiatry London J & A Churchill 1957 Pp 328 45s

SINCE the time of Ehrlich the term "chemotherapy" has usually been restricted to chemical treatment which destroys some infecting organism (bacterium or parasite), but by its derivation it ought to include all treatment by chemical compounds Dr McIlwain uses the term in the wider sense, and his book considers chemical compounds which have been used to produce all kinds of therapeutic effects in the central nervous system

His approach is mainly historical, starting from 1800 and leading up to the most recent developments Thus, successive chapters describe general anæsthetics and hypnotics, antipyretics, the distribution of drugs in the body and their metabolism, the action of drugs on the body and on the disturbing agent, drugs acting on infections (arsenicals and other compounds against trypanosomes and syphilis, sulphonamides, and antibiotics), and the theory of antimetabolites developed from them, anticonvulsant and drugs for the treatment of epilepsy, and drugs for nervous and mental disorders, both those which are mainly excitant (e g, amphetamine, pipradol) and those which are mainly depressant (e g, reserpine, chlorpromazine) Finally, there is a chapter which considers the general principles of discovering new drugs for action upon the central nervous system

The book does not attempt to give technical details or exact data, but rather considers general principles, and the author is to be congratulated on having told a complex story in a simple and intelligible style, which does not need a detailed knowledge of chemistry or pharmacology for its appreciation He will find ready readers among doctors who are interested in knowing the background of the drugs they use, and among research-workers, pharmacologists, and synthetic chemists engaged in the search for new remedies

Gynecologic Surgery and Urology

THOMAS L BALL, M.D, assistant professor of clinical obstetrics and gynecology, Cornell University Medical College London Henry Kimpton 1957 Pp 547 150s

BRITISH gynæcologists perhaps do not realise that in many centres in the United States gynæcology and female urology are almost one specialty Dr Thomas Ball's beautiful volume of operative gynæcology might well have been entitled Female Pelvic Surgery, since it includes some basic proctology in addition to urology and gynæcology The reader will b impressed with the accurate anatomy and the thoughtf and meticulous approach of the anatomically trained surgeo to each clinical problem, which is illustrated by some of th finest drawings to be found in any similar book

The scope is considerable and includes many importa problems which are not strictly surgical, such as the psychosomatic aspects of gynæcological surgery, and a particularl thoughtful chapter on backache in women The general substance of the book is in line with the best modern British gynæcological practice, and the style of the author is clear and at times, refreshingly racy The chapter on malignant tumours, radiation, and radical surgery is perhaps the best, and includes some of the more recent advances in radiation therapy

British gynæcologists should not be deterred by the price o this lavishly produced and generously illustrated book, for by spending it they will broaden their attitude to gynæcology and they will find much to stimulate and instruct them

The Sea My Surgery

JOSEPH MAGUIRE, M B London William Heinemann 1957 Pp 234 16s

Dr Maguire has been a ship's doctor for thirty years, and for fifteen of them he has been serving in the *Queen Mary* or the *Queen Elizabeth* Even the least gifted of writers would find it hard to write a dull book with that sort of experience behind him—and Dr Maguire is certainly not in that category He tells his story with all the gift for raconterie which on might expect from an old sailor who is also an Irishman

To remind us that, even on one of the Queens, a shi doctor's life is not concerned exclusively with tending f stars with headaches, there are several accounts of more d perate emergencies—sometimes fought out with hundreds miles separating the doctor and his patient, whose condit had to be diagnosed and treated by radio One of the m interesting chapters recalls a period when conditions were so luxurious Dr Maguire sailed in the *Queen Elizab* throughout the late war, when she was used for trooping S then carried up to 15,000 soldiers at a time, but in a mann which denied them most of the comforts the peacetime p senger expects (The better state-rooms on the main de for instance, which normally accommodated 2 persons, w reserved for colonels—26 to a room!) There are intrigu glimpses of the organisation which made possible this m transport of men, and which surmounted such tasks as cook 31,000 eggs for breakfast

The Disease of Tobacco Smoking and its Cure

LENNOX JOHNSTON, M B London Christopher Johnson 19 Pp 104 3s 6d

SMOKING has been shown to be partly responsible f bronchial carcinoma, pulmonary tuberculosis, corona occlusion, thromboangiitis obliterans, and tobacco amblyopia not to mention the fires and mine explosions it causes, and t road accidents attributable to cerebral ischæmia due to ca boxyhæmoglobinæmia There is little to be said in favour smoking, and the world would no doubt be a happier place it were abandoned Dr Johnston has been saying this wi some force for years, and he has now written a summary of t evidence against smoking, an account of his alarming expe ments on himself with nicotine, and a history of his campaig We wish him success, but we must unhappily forecast that t tone of his book will incense most smokers rather than convinc them of their errors They may be frightened into givin up their addiction, they will not be persuaded by thes methods

The book may better serve a purpose in helping those wh have decided to stop smoking, there are hints and encouragement, and suggestions for forming a stalwart mental attitud against smoking An appendix gives verbatim the recent statement by the Medical Research Council on tobacco-smokin and cancer of the lung

THE LANCET

LONDON 4 JANUARY 1958

Incidental Dangers of X-ray Therapy

Belief in the relative "radioresistance" of certain organs and tissues which may have to be included in therapeutic X-ray fields prevailed for many years But in the past decade that comfortable conviction has been rudely shaken, and to long-established hazards, such as radiation burns and bone-marrow aplasia, further disquieting possibilities have been added Major damage to the kidney, to the central nervous system, to the lung, and probably to the heart-muscle must now be included among the risks of radiation

The clinical and experimental work of Prof Clifford Wilson and his colleagues, whose report we publish this week, demonstrates that irradiation of the kidney may produce hypertension which, both clinically and histologically, is indistinguishable from malignant essential hypertension This discovery that renal hypertension can be induced without obstructing the renal circulation and in the absence of manifest renal damage is of great interest It opens new possibilities for the role of the kidney in the genesis of chronic hypertension, and particularly of essential hypertension, where a renal mechanism has hitherto appeared less likely because, in the early stages, there are no structural changes in the kidney These observations confirm and explain in a remarkable way the different clinical syndromes described by Luxton [1] in his account of radiation nephritis The pathological features of this nephritis were reported by Russell,[2] and the limits of renal tolerance to X rays were carefully assessed by Kunkler et al [3]

Boden [4] examined 161 patients who had been given X-ray therapy for malignant growths of the mouth and neck, and found 10 with radiation myelitis of the cervical spinal cord, which was fatal in 5 cases Boden [5] later reviewed 7 cases of radiation myelitis of the brain-stem, and thus confirmed and greatly expanded the work on isolated cases of Ahlbom [6] Smithers et al,[7] and Stevenson and Eckhardt [8] Cerebral damage from radiation has been similarly recognised clinically by Wachowski and Chenault [9] and Pennybacker and Russell [10] Radiation damage to the lung was first described by Groover et al [11] and was brought clearly again to our notice by Whitfield et al [12] who recorded 29 cases. Whitfield and Kunkler [13] described 4 patients with electrocardiographic changes following X-ray treatment to the thorax Furthermore, the threat of leukæmia from X-radiation seems real enough, evidence coming from studies of patients with ankylosing spondylitis treated with X rays,[14] from the incidence of leukæmia in children given X-ray treatment in infancy for enlargement of the thymus,[15] from the increased death-rate among physicians practising radiology,[16–18] and from the death-rate from leukæmia attributable to the atomic explosions in Nagasaki and Hiroshima [19–21]

Radiotherapy is of immense value as radical treatment for certain malignant growths, especially cancers of the skin, lip, tongue, and uterine cervix, and is used as palliative treatment for many other types of neoplastic disease There is also a sound basis for prophylactic irradiation of the abdomen after unilateral orchidectomy for seminoma [22]—a practice which drew attention to the nephritis caused by X rays

X-ray therapy having been in vigorous use for over thirty years, it may be asked why its clinical side-effects have not been investigated more closely Forssell [23] stated emphatically "A medical man who devotes his services to a radiotherapeutic clinic must forsake all else and be willing to devote life and soul to radiotherapy" Is the old adage relevant here—"Love is blind but the neighbours ain't"? The radiotherapist may seem somewhat uncritical of the side-effects which alarm his colleagues There are, however, important contributory factors Commonly a latent period of weeks or months divides the start of X-ray therapy from the development of symptoms of incidental X-ray damage It has been only too easy to dissociate such symptoms from the X-ray therapy and to attribute them to metastases or to an extension of the primary growth—and even to prescribe further X-radiation on that account Furthermore, a feature of X-ray therapy is the variation in susceptibility between patients, as between individual tumours Also, radiotherapy is a developing science, new techniques with incompletely known effects are constantly under trial But perhaps the main difficulty is that the radiotherapist's attention is focused on the malignant growth He knows that the patient's survival depends on its eradication, and, half-measures being fraught with peril, makes the primary treatment as radical as possible

It profits all concerned, especially the patient, if radiotherapists work in close association with clinicians "Combined clinics" are now widely established in which radiotherapist and surgeon or gynæcologist see the patients together, and seek to agree on diagnosis and treatment Radiotherapy should not be isolated It should be part of a general scheme, and those who conduct it should maintain constant contact with both physicians and surgeons in diagnosis, treatment, and

follow-up Much is already being done to avoid the incidental dangers of X-radiation—for instance, by using megavoltage and by "shielding" techniques But radiotherapy remains a powerful weapon which can be fatal to both friend and foe, and the whole resources of medicine are required to ensure that its edge is turned always against the invader

Influenza Vaccines

THE circumstances of the recent influenza epidemic have been unique in many ways From the time when the so-called Asian viruses first appeared and showed their ability to spread, it was clear that a world-wide epidemic could be expected Accordingly in many countries, including the U S A and this country, there was a short period during which vaccine could be prepared in readiness for the epidemic Plans were made in the U S A, and to a lesser degree in this country, to use vaccine on a larger scale than ever before To some extent these plans were disorganised by the fact that the epidemic got under way well ahead of winter—the usual season for influenza epidemics At the moment the epidemic is on the wane, but a second wave may come later in the winter

It is too early yet to judge how effective the influenza vaccine has been, this information can only come from controlled trials carried out under various conditions In a small trial [1] 70 volunteers in an American State penitentiary were vaccinated last July with either Asian vaccine or an inert fluid, in such a way that neither the volunteers nor the clinical observers knew which inoculation had been given to each individual Three to four weeks later 55 of the volunteers were inoculated with live Asian virus in the form of a pool of nasopharyngeal washings collected from Boy Scouts who took ill while attending a jamboree Volunteers first received an instillation of saline into their nostrils in order to clear away all mucus, and then the inoculum was sprayed into each nostril and into the oral pharynx by means of a De Vilbiss atomiser, and the oral pharynx was also swabbed vigorously with a swab dipped in the inoculum It was calculated that each volunteer received about ten thousand infective doses of virus, corresponding to one or two drops of nasopharyngeal secretion Altogether 78% of 23 volunteers in the control group developed influenza, compared with 44% of 32 volunteers in the vaccinated group Clearly the results of this limited trial, in which an artificial method was used for inducing infection, can be taken as only a very rough guide to what may be expected under natural conditions of exposure to infection Nevertheless the findings suggest that the vaccine is unlikely to have dramatic protective effects, and unofficial reports of its behaviour under natural conditions are in line with this conclusion

The results of previous trials of influenza virus vaccine have varied, in some epidemics protection-rates of 70–80% have been found, while in others vaccine has shown no beneficial action The most variable factor is the virus itself, which seems to have an almost unlimited capacity to mutate from one epidemic to the next, and the best protection-rates have been found when the virus used in preparing vaccine was antigenically closely related to the epidemic virus The virus responsible for this latest epidemic is antigenically remote from previous influenza-A viruses [2] It is therefore possible that a single inoculation of vaccine would not protect as well as two inoculations, and this is one of the questions which may be answered by trials now in progress This possibility was suggested by a vaccine study [3] among schoolchildren in this country Unfortunately it seems that knowledge gained from one vaccine trial cannot be readily used to predict the protective value of a new vaccine in a changed epidemiological situation, and clearly we do not know enough about the epidemiology of influenza and the best use of influenza vaccines to allow us to keep one step ahead of the virus At the moment, while influenza is relatively mild and the degree of protection given by Asian-virus vaccine is still unknown, the decision how widely to use vaccine will be dictated mainly by political and economic factors

Hospital and Home

IF hopes are seldom realised in full, neither are fears At the beginning of a year which will see the tenth birthday of the National Health Service, we can take comfort from its continuing state of flux Instead of settling in a solid mould, as was predicted, it remains malleable enough to be adapted to new circumstances and new ideas of what the public needs Already some remarkable changes are beginning

Medicine, of course, is in a highly dynamic phase, which refuses to be bound by calculation and prophecy Thinking of projects into which we have put our heart, some of us may reflect half ruefully on the effort we put for instance, into pressing Governments to take tuberculosis more seriously and provide a great many more beds for its treatment On which Dr BERESFORD's letter in our correspondence columns this week is sufficient comment, for he is suggesting that the larger sanatoria should now be made over to other purposes Again, in face of the shocking overcrowding of mental hospitals, it must have seemed to many that the urgent need was to relieve pressure by putting up new buildings But the paper by Dr CARSE and his colleagues (p 39) shows once more that such thinking is out of date From the varied experience of such enterprising places as Amsterdam, Nottingham, Manchester, Bristol, Bromley, the Maudsley, and now Worthing, a quite different system of looking after mental disorder is beginning to emerge—a system in which most of the patients will go on living at home while under treatment and will get the benefits of psychiatry, at day hospital or clinic, without risk of the desocialisation too often suffered in the past by those who have entered large and often isolated institutions Within ten years, at latest, we may be wondering what to do with the many mental hospitals which are plainly unsuitable for the proper practice of psychiatry within the same framework as the rest of medicine.

Both in tuberculosis and in mental disorder we see examples of the new tendency to treat the patient at home in his natural surroundings. Similarly it is clear that a great many old people who have been forced into institutions ought to have had the kind of help that would enable them to go on living independent lives, often far more happily. There is always a risk that, with any new movement like the present endeavour to keep patients out of hospital, one may end up by sacrificing people to the idea: there are some mental patients, and some old people, and indeed some children, who can be kept at home only at immense cost in strain to their relatives—no matter what aid they may get from doctor, home nurse, health visitor, or home help. Indeed, home care can be financially much more expensive than hospital care, and cannot therefore always be preferred even on economic grounds. Nevertheless we are certainly witnessing the development of fresh arrangements by which many more patients will visit the hospital instead of living in it. And we are also witnessing a change in the nature of the hospital itself. At last people are getting away from the rigid concept of a hospital as consisting of a collection of similar wards, each staffed by a complete hierarchy of trained nurses, to which every patient who needs specialised investigation or treatment must be admitted. Many years' experience has shown how much can be done in outpatient departments without entering the wards, and still more could be done if suitable patients could have hostel accommodation overnight. Similarly many patients necessarily admitted to ordinary wards could, as they recover, graduate to wards without nursing supervision, where some of them could virtually look after themselves while obtaining whatever treatment they need. What has been wittily called "cafeteria medicine" surely has a real future, for it is futile to waste the service of skilled nurses on people who do not in the least require them.

In returning thus to the old theme of keeping patients out of hospital, we return also to the question of where the centre of gravity of medicine really is or should be. Are the hospitals merely an appendage to general practice, where 90% of the patients are seen and treated? Or is the hospital the true temple, and the family doctors no more than mobile acolytes? We have repeatedly stated our opinion that, wherever the exact balance lies, grave damage will be done if the general practitioner ceases to regard himself as an all-round doctor capable of accurate diagnosis and treatment, and responsible for the care of patients rather than for the disposal of applicants. And in some ways the new trend towards keeping the patient at home, and bringing the specialist to his hearth, may help to restore the practitioner's position. On the other hand many of the present promising experiments—for example, the Worthing trial of domiciliary psychiatry, the Cambridge scheme for discharging patients early, with extra nursing care, the St Mary's Hospital pædiatric team which goes to illness in the home[1]—are essentially extensions of hospital work: the hospital is sending out pseudopodia, and though these may make useful contacts with general practitioners they do not necessarily increase the activity or scope of general practice. Likewise the development of hospital departments for looking after special groups of people in an area, such as the epileptic or the spastic, may lessen rather than stimulate the family doctor's sense of being in ultimate charge.

Those who care about the future of general practice should, we think, be paying close attention to the process by which the hospital is projecting itself ever further towards the home. We for our part welcome this development as often realistic and helpful, but we still believe that everyday medical care should be given by an independent family doctor, directly responsible to his patient, and not by a hospital medical officer however mobile. All too clearly, general practice on a high level is not going to be preserved unless those who have faith in it are prepared to translate that faith into works.

SYRINGES: CLEAN OR STERILE?

Of the many unsatisfactory ways of attempting to sterilise syringes in hospital, the commonest is boiling. Even in favourable circumstances this method does not eliminate spores, and circumstances may be so unfavourable that non-sporing organisms escape. Thus a doctor or nurse in a hurry may use a syringe after less than five minutes' boiling, or contaminated material may be put in the steriliser just before the syringe is removed. Some hospitals now have a central service, where syringes are autoclaved and wrapped for distribution to wards and departments; others (we hope all) will want to institute one. The Nuffield Provincial Hospitals Trust has done well to produce a little book[1] which sets out clearly and concisely all the information needed for the purpose. It represents the work of an operational research team who have investigated some existing syringe services.

The first chapter is so detailed that it amounts almost to a blueprint for building a department. The second describes the most economical way of running the department, and suggests means of greater economy when newer apparatus is to be had. The third shows that the capital outlay for a capacity of 500 syringes a day would at present be about £1600 and the running costs (including syringe and needle replacements) £3725 a year, or about *5d* a syringe. A service on a national or regional scale would not be more economical than one on a group or hospital scale. Capital depreciation is not considered, and the cost of "sterilising" syringes by boiling is only briefly discussed. A central service would make for some saving in that ward sterilisers are apt to be left boiling too long, with waste of fuel, and are costly to maintain; the saving would be appreciable if all sterilisation (not merely of syringes) were done centrally.

The safety, convenience, and possible economy of central syringe-sterilising services strongly commend the method to all hospitals, and anybody planning one now has useful guidance at hand.

BARBITURATES AND GLUCOSE

It has been recognised for some years that the injection of hypertonic glucose into an animal awakening from barbiturate narcosis will reinduce anæsthesia[1] This response has been investigated in man by Dhuner and Nordquist,[2] who were prompted by the chance observation that administration of cortisone to a patient recovering from an overdose of phenobarbitone returned him to a state of deep unconsciousness (Their report appears in the first issue of *Acta Anæsthesiologica Scandinavica*[3])

A series of 20 further patients was observed, of whom 18 had had an overdose of a single identifiable barbiturate and 2 an overdose of promethazine Of these 20, 13 received 50–100 mg of cortisone intravenously or intramuscularly and 7 9–12 g of glucose intravenously in a 30% solution immediately they had awakened from the intoxication Unconsciousness, assessed clinically in all cases and by electroencephalographic tracings in 6, was reinduced in some degree in 16 cases—in 8 to a level approximating to that on admission A control series of non-intoxicated patients who received similar quantities of cortisone or glucose showed no effects of any kind

Dhunér and Nordquist cannot explain these findings They found no change in the plasma-barbiturate level after injection of glucose, but an occasional fall (which was not correlated with the clinical effects) shortly after administration of cortisone They rightly stress the potential clinical importance of such reinduction of unconsciousness not only in the treatment of barbiturate or promethazine poisoning, but also in anæsthetic practice

GERIATRICS IN THE HOME

With the Ministry of Health again rightly pointing out that old people who are unwell should if possible be cared for at home instead of being admitted to overcrowded hospitals,[4] the report of a pilot experiment in geriatric reablement in the home should be of great interest not only to administrators but to every family doctor

This experiment[5] was undertaken by the geriatric unit of the Belfast City Hospital, with the help of £5000 provided from the Nuffield Provincial Hospitals Trust, and its basis was a belief that there are elderly invalids who are getting good home care but nevertheless risk delayed recovery, or even permanent bedfastness, through lack of reablement facilities which are usually to be had only in hospital If these facilities were brought to the home, might not the burden of ill-health—on patient and relatives alike—be lightened and the demand on long-stay hospital beds lessened? The report recounts how the need was established and how the cases for trial were selected Of 272 patients initially referred by their doctors, 85 were thought suitable, 37 of these being hemiplegics and 28 cases of arthritis Medical assessment by the visiting geriatric physician was the basis of the advice on nursing management and general care In treatment the mainstay was physiotherapy—with emphasis on what the patient and relatives could do for themselves After courses of up to 50 treatments (though often much fewer) it was judged that about two-thirds made a satisfactory recovery Though the cost of the treatment averaged 15*s* 9*d* for each visit by the physiotherapist, to get similar results with the patient in hospital would have cost considerably more

Dr Adams and his colleagues are certainly not pleading for unrestricted home physiotherapy Less than a third of the patients referred were in fact thought suitable, and in making this decision good home circumstances were considered as important as a medical condition capable of improvement The conclusion that "home treatment and rehabilitation has been successful within the limits defined" is qualified by its description as "a useful aid to comprehensive home care services for the aged" rather than an end in itself For most of the aged sick at home, who would be unlikely to benefit from treatment of this kind, the Belfast team believe that more could be done if the existing services provided by statutory and voluntary bodies were better coordinated They suggest that every area should have a counselling centre to which the general practitioner could turn, and which could provide a skilled social worker (preferably a health visitor) to assess the home situation, with power to focus all the necessary services where they are needed This valuable recommendation supplements the growing feeling that such, indeed, is an important function of the health visitor of today and tomorrow

PORTOPULMONARY ANASTOMOSES IN HEPATIC CIRRHOSIS

Over twenty years ago Snell[1] observed that in some patients with hepatic cirrhosis the oxygen saturation of the arterial blood was reduced That this was not due to any impairment of gaseous diffusion from the pulmonary alveoli to the capillaries was shown by Abelmann and his colleagues[2] in Boston These findings could only mean that a considerable volume of venous blood was diluting the arterial blood in the pulmonary veins, and, since there was no reason to suppose that this was coming from underventilated areas of lung, the most probable source was portal blood shunted into the pulmonary venous system Calabresi and Abelmann[2] therefore sought to demonstrate the anastomotic channels

Anastomoses between the pulmonary and azygos veins via the bronchial veins have long been known to exist, and the possibility that portal blood followed this route was investigated In 20 cadavers the portal vein was injected in situ with a radio-opaque lead gelatin mass too viscous to enter vessels below 40 µ in diameter The mass was coloured with methyl-green so that its distribution could be readily followed both by dissection and by radiography Of the 20 bodies studied, death had been due in 10 cases to cirrhosis of the liver with ascites and in 6 to congestive cardiac failure In the remaining 4 cases there was no significant cardiac or hepatic disease In each of the cirrhotic cases there were dilated and tortuous periœsophageal veins injected via the coronary and short veins of the stomach These periœsophageal veins anastomosed freely with veins in the posterior mediastinum, with pleuropericardial veins, and, via the azygos veins, with the superior vena cava Moreover, in 4 of the 6 cadavers in which a satisfactory injection was achieved, the posterior mediastinal veins anastomosed freely with peribronchial veins at the tracheal bifurcation and with the bronchial veins of the main-stem bronchi

1 Snell A M *Ann intern Med* 1935, 9 690

2 Calabresi P Abelmann W H *J clin Invest* 1957, 36 1257

In one preparation a vessel was found running directly from the posterior mediastinal plexus to a tributary of a right pulmonary vein, while in 2 of this group the injection had reached the pulmonary veins and the left auricle and ventricle. In the cases of congestive heart-failure all 5 cadavers adequately injected showed gross anastomoses between the portal system and bronchial veins via the periœsophageal, mediastinal, and pleuropericardial plexuses, but in no case did the injection mass reach the heart or main pulmonary veins. A somewhat similar result was obtained in the cases with no cardiac or hepatic disease, but the injected vessels were invariably fewer and smaller than in the cirrhotic and cardiac groups.

The pressures in the portal and pulmonary venous systems in health are approximately the same. It is therefore theoretically possible for blood to flow from one to the other whenever the pressure in either system is pathologically raised, and the anatomical findings of Calabresi and Abelmann strongly suggest that such a diversion of flow actually occurs. Their radiographic demonstration of a dilated azygos vein in 5 living cirrhotic subjects and 4 with congestive heart-failure—i.e., in all cases where satisfactory pictures were obtained—is further evidence of the functioning of this anastomotic system.

PAIN

THE possibility of pain appeared when life first began, and the capacity to react to injurious stimuli was the earliest protective mechanism to develop. The power to perceive pain came later with the appearance of a complex nervous system. In the most highly developed animals a great variety of extra- and intra-corporeal stimuli can produce a sensation of pain, and in man, among the internal stimuli, disordered thought and emotion can give rise to sensations of pain alleged to originate in a somatic region. In all ages there have been theories to account for pain, from the primitive idea that it is always inflicted from without, by enemies or spirits, and can be extracted by mechanical or magical means, to the highly philosophical hypotheses of some of the Greeks. Many of the Greek ideas seem remarkably like those of our own times, though in fact a superficial similarity of principle covers a wholly different background of knowledge and speculation. On the other hand, it is possible that the meaning was closer to our own than we think, because though certain words can be translated, the contemporary significance of them has been lost. Not until the anatomy of the nervous system was at least partially known could rational theories on the cause and perception of pain be developed, but we are still unsure of the peripheral and central mechanisms of pain.

As Dr K. D. Keele points out, in a fascinating account[1] of the knowledge, or anatomies, of pain from primitive times to the present day, we are apt to think that only the present or immediate past has made any notable contribution to the problem. It is salutary to realise that Galen believed the sensory and motor nerves to be separate, and that the brain received all sensations. He even performed the experiment of hemisection of the spinal cord and noticed the paralysis on the same side as the section, but failed to notice the contralateral sensory loss. In this field, as in so many, the ideas of Leonardo da Vinci were well in advance of those of his contemporaries.

Despite the great amount of work that has been done in the past 150 years, we are still unable to explain the diversity of pain sensations or to describe many of them, just as we still do not know where and how pain is perceived. As Keele says, there is now a strong tendency to return to the idea of a sensorium commune and say with Harvey that "we do not feel with the same sense by means of which we are conscious we feel ... but by another sense or sensitive organ ... by which we examine those things that reach us through each of the external sensoria."

ANTIBIOTIC PROPHYLAXIS

IN discussing the abuse of antibiotics we have deplored the routine employment of these drugs as prophylactics.[1] More often than not, the belief that antibiotics will prevent bacterial infections is unjustified, and their misuse in this fashion is potentially hazardous. Enumerating what he held to be the legitimate uses of prophylactic antibiotic therapy Garrod[2] pointed out that the suitable occasions are specialised and relatively uncommon. To use antibiotics for clean operations with the object of escaping wound sepsis or respiratory complications is a vain hope, as a gesture it represents lack of confidence by the surgeon in his own or his staff's aseptic technique. Moreover, even when there is a proper indication for antibiotic prophylaxis, it is often impossible to prevent bacterial infection in this way. There is good hope of success in preventing specific infections due to bacteria that are always sensitive to a particular drug—for example, in the successful prevention of group-A hæmolytic streptococcal infection and its complication, rheumatic fever, with penicillin, and of meningococcal infection with sulphonamides. Results are not so good, however, if cover is required against a variety of organisms that may be resistant to the agents used. Pulaski[3] in a recent brief review refers to reports of unsuccessful prophylaxis in these circumstances. Antibiotics failed to prevent bacterial complications in measles and in cases of poliomyelitis with tracheotomy. Among patients undergoing operations on the biliary tract, subtotal gastrectomy, or resection of the colon with anastomosis, postoperative complications were as common in those who received antibiotics as in those who did not, and the incidence of wound infections after appendicectomy for acute suppurative and acute gangrenous appendicitis was not reduced by parenteral tetracycline therapy.

Antibiotics are often prescribed as a prophylactic for unconscious patients, and Petersdorf et al.[4] have evaluated this procedure in a careful study of 72 comatose patients. Unconsciousness was generally the result of a cerebrovascular accident. Some of these patients received antibiotics either singly or in combination, others did not. No benefit was derived from the chemotherapy, on the contrary, patients given antibiotics were more susceptible to pneumonia, cutaneous staphylococcal infections, and bacteræmia due to gram-negative bacilli. Chemoprophylaxis did not reduce nasal or nasopharyngeal carriage of *Staphylococcus aureus*, and the strains isolated from the treated group were more resistant to antibiotics than those cultured from the controls. Replacement of the nasopharyngeal flora by gram-negative bacilli was commoner in those receiving antibiotics. Routine administration of antibiotics did not prevent infection of the bladder in patients with indwelling urethral catheters but often resulted in the infecting organism being a highly resistant proteus or pseudomonas Petersdorf et al concluded that, far from being beneficial, antibiotic prophylaxis in these patients was distinctly risky

[4] Petersdorf, R. G., Curtin, J. A., Hoeprich, P. D., Peeler, R. N., Bennett, I. L. *New Engl. J. Med.*, 1957, 257, 1001.

The danger of widespread chemoprophylaxis is not only to the patient himself but also to the hospital community at large, for every patient given antibiotics may become a source of highly resistant organisms In situations where infection is a risk the best policy is one of watchful waiting and vigorous treatment of specific intercurrent infections if they develop But, since prevention still is better than cure, there is also a need for some fresh reviews to be made of the "aseptic regime" as practised in our hospitals, especially in the wards and casualty departments

TOTAL ADRENALECTOMY IN MALIGNANT HYPERTENSION

As long as hypertensive disease remains in the benign phase the physician can afford to take his time in deciding on the best course of treatment, whatever his misgivings about the term "benign" But once the malignant phase is entered, he faces a desperate medical emergency in which every day counts, because the high blood-pressure has now begun to cause renal damage of a kind which will generate secondary hypertension and soon render the disease irreversible If left untreated this process is virtually certain to kill the patient within months On the other hand if the pressure can be reduced early enough and kept under control—not necessarily at a normal level—the malignant process can often be held indefinitely in check

One possible way of doing this is to remove both suprarenal glands But since the adrenal cortex is essential to life, and has complex and poorly understood functions which can be only partly restored by substitution therapy, its total removal cannot be contemplated without misgiving

It is true that the blood-pressure is low in adrenal insufficiency and high in certain rare forms of cortical overactivity in man, and also that the level of experimental renal hypertension can be lowered by adrenalectomy and restored by treatment with cortical extracts These facts and many others leave no room for doubt that the suprarenal cortex plays an important part in the normal control of blood-pressure But so do many other factors, and it would be unwise to conclude from the available evidence that the suprarenal cortex is vitally concerned in the pathogenesis of essential hypertension In these circumstances adrenalectomy must be regarded simply as one of a number of ways of lowering blood-pressure, neither more nor less empirical than administration of hexamethonium or reserpine None of these corrects the essential abnormality of hypertension, and treatment at present is largely a matter of steering an uncertain course between the opposing evils of excessively high pressure on the one hand and excessively low pressure on the other

How has adrenalectomy worked in practice? Professor Melville Arnott and his associates [1] have lately reviewed the published reports on this question Much of the evidence is difficult to assess because commonly adrenalectomy has been subtotal or has been combined with other measures, owing to a proper concern with helping the individual patient rather than answering a general question But with generous allowance for the inadequacy of the data and the serious condition of the patient, the results of adrenalectomy do not make cheerful reading The immediate mortality is disturbingly high, and of the survivors the proportion whose symptoms persist and who die later on is not encouraging Arnott et al felt that a more precise assessment was needed because of the evidence relating the suprarenal to hypertensive disease, which they regard as strong, and they decided to make detailed studies in a limited series of six patients with malignant essential hypertension who had failed to respond satisfactorily or were intolerant to intensive treatment with oral or parenteral antihypertensive drugs Their criteria in assessing response or intolerance are not stated, but severe renal failure was regarded as contraindicating adrenalectomy

After 20–30 days' rest in bed without other treatment, bilateral adrenalectomy was performed under general anæsthesia Cortisone treatment was started the day before operation, the dose being reduced as soon as possible afterwards, and detailed clinical and laboratory observations were continued for many days Of the six patients three died within 8 weeks of the operation one within 36 hours from a precipitous fall in blood-pressure with extensive cerebral damage, a second on the 6th day from ventricular failure following a steep rise of pressure, possibly due to too much cortisone, and the third from a cerebral thrombosis 53 days after the operation The remaining three patients are all alive, two after 2 years and one after 18 months, and in a satisfactory state although signs of mild adrenal deficiency have developed, and a slight increase in the dosage of cortisone quickly recalls a severe hypertensive state

Thus adrenalectomy may, like antihypertensive drugs, reverse the malignant phase in essential hypertension, but, as Arnott et al point out, it should not be undertaken unless medical measures have failed, and it should never be attempted in the presence of frank renal failure At the same time the experience of Arnott et al confirms earlier reports that total adrenalectomy in malignant hypertension is an extremely perilous undertaking which has no specific effect on the underlying hypertensive state, and many physicians may prefer to persevere with vigorous medical treatment

MINOR METAMORPHOSIS

At this New Year we have changed the type in which the text of *The Lancet* is printed Our object is to make it, on the whole, easier to read, without much loss of matter Having waited long but vainly for someone to design a new type which would be both suitable and very modern, we have reverted instead to one of the old masters of typography Christophe Plantin (1514–89) would scarcely recognise the type named after him indeed the original fount is now said to have been cut by Garamond or Granjon But the Monotype version of Plantin which we are now using is both traditional and well proven, having given good service since it was issued in 1913

To those who liked our pages as they were, we are grateful, but we hope that they may in time get used to the new ones Meanwhile they will recognise that occasional metamorphosis is a biological necessity for a journal as for other larval organisms The ultimate imago is beyond our present imagining

From Graylingwell Hospital, Chichester

FOR over a century, psychiatric practice in Great Britain has put its emphasis on inpatient treatment, and the public have come to believe that little can be done outside the mental hospital. Up till 1930 there were few outpatient clinics, little encouragement was given to seek early treatment, and positive action was taken only after the illness was fully established and admission under certificate to a mental hospital was unavoidable. Even today, for the great majority of mentally ill patients, treatment still means admission to hospital. The psychiatric units attached to teaching hospitals are primarily intended for teaching and research, and, though outpatient clinics at general hospitals provide some therapy, large numbers and shortage of time oblige them to refer to mental hospitals most of their patients who need treatment. Any mental hospital which cares to examine its records will find that from half to three-quarters of its admissions come from the clinics.

Faced with a continuing increase in the number of admissions, together with serious overcrowding, our mental hospitals will soon be unable to meet the demands made on them. Admissions to designated mental hospitals in England and Wales rose from 55,856 in 1950 to 71,699 in 1954, and to 78,586 in 1955. By 1955 these hospitals were overcrowded to the extent of 17,965 patients. Clearly immediate action is essential if the required treatment is to be given. One solution is build more hospitals, but this, however, is impracticable because of the cost and the difficulty of staffing. A possible alternative is to spread the load by greatly expanding outpatient treatment facilities.

In 1956 the South West Metropolitan Regional Hospital Board, with the financial help of the Nuffield Provincial Hospitals Trust, decided that Graylingwell Hospital should undertake a two-year pilot experiment by providing an outpatient and domiciliary treatment service based on the coast town of Worthing. The service began on Jan. 1, 1957.

The First Ten Months

The area covered extends about 9 miles eastwards, 9 miles westwards, and 8 miles inland, and covers a population of 160,000 people. All patients, except a few sent from the magistrates' courts, are referred to the service by their family doctors. We insist on this because we are convinced that a close and friendly liaison with the patient's own doctor is essential. No patient is admitted to Graylingwell from the Worthing area without being screened by the service, and thus ensures that hospital treatment is reserved for those cases in need of it.

Worthing and district were chosen for this pilot scheme because they are sufficiently remote (22 miles) from the parent hospital, Graylingwell, to show if it is possible to provide psychiatric treatment for large numbers of patients without the immediate availability of the resources of a modern mental hospital. Another reason was the variety of the population. There are people living in busy towns and others in hamlets and villages, some remote and isolated. There are retired, professional, business, industrial, and agricultural classes. Worthing itself has one of the highest proportions of elderly people of any town in England or Wales, and how far it is possible to treat as outpatients the aged who become psychiatrically ill is a matter of urgent concern to us.

The headquarters of the service are housed in a 20-bed unit, already belonging to Graylingwell, which is now also used as an active treatment centre and day hospital. There are no resident patients.

Working in the service are two full-time and one part-time psychiatrists (five half-days per week). There is always one trained psychiatric sister living at the treatment centre, and during weekdays there are also two staff nurses and two ward orderlies. Staff for the treatment of male patients is supplied from Graylingwell by the chief male nurse who, with the matron and their senior staff, visit the centre periodically. The social work is done by one psychiatric social worker and one hospital almoner. Occupational therapy is organised and supervised by one senior occupational therapist. The secretarial work is done by one medical secretary with part-time clerical help (four half-days per week) supplied by the hospital.

The Patients

In the first ten months the service dealt with 1192 patients (376 men and 816 women) of whom 1110 were new cases. The other 82 were patients who had had psychiatric treatment before Jan. 1, 1957, and are now receiving follow-up supervision and treatment through the Worthing service. 318 of the patients were sixty-five years of age or over.

The psychiatric outpatient clinic of Worthing Hospital is included in the service and 421 patients were seen there. This close link with a general hospital has already proved of great advantage. 339 patients were seen by appointment at the treatment centre. This part of the service is much appreciated by the family doctors because the patients are examined and a report sent promptly and there is no need to wait for a vacancy at the clinic.

Treatment

Over 1000 domiciliary visits were paid by the psychiatrists to 432 patients. Often more than one visit is necessary, and with the assistance of the social worker we are often able to help the patient and his relatives to sort out difficulties which are largely responsible for the breakdown. This work is exacting and time-consuming, but we believe it is sometimes better psychiatric treatment than to allow the patient to run away from his problems by sending him into hospital. No fee was received for any of these visits.

Patients cannot be effectively treated as outpatients unless extreme care is used in physical treatments. Each of our patients first has a thorough physical examination and a comprehensive laboratory investigation before treatment is begun. These were carried out at the department of pathology at Graylingwell Hospital.

Among the outpatients attending the treatment centre electroconvulsant therapy has been used extensively. The courses are short, averaging only 4.9 treatments. Although this is less than is usually given to inpatients, it has proved adequate and so far few patients have relapsed. As it is not necessary to enter hospital, patients are willing to be treated earlier in their illness and need only this shorter course.

Modified insulin has also been used to good effect in the treatment of tension states. The patients spend the day in the treatment centre, and to avoid complications only a low dosage is used, but the course is lengthened if necessary.

Individual psychotherapy is the main treatment for many patients, and is, of course, given to all patients attending the centre A weekly session of group psychotherapy is also held Details of the treatments given up to Oct 31 are

—	Electrical treatment		Modified insulin		Psychotherapy		Drug abreaction	
	M	F	M	F	M	F	M	F

Effect on Hospital Admissions

The number of admissions to Graylingwell Hospital and Summersdale Hospital (its non-statutory short-stay unit for recoverable patients) from the area served by the Worthing and District Mental Health Service during the first ten months of 1957 fell by 324 (59%), compared with the same period in 1956 (table I) Admissions from the rest of the catchment area of the hospital increased by 23, though 1956 was the year with the highest admission-rate in the history of the hospital, which suggests that the demand for psychiatric treatment is still increasing

TABLE I—ADMISSIONS TO GRAYLINGWELL HOSPITAL AND SUMMERSDALE HOSPITAL

—	1956	1957	Difference
Admissions from catchment area served by Worthing service	548	224	−324 (−*59%*)
Admissions from catchment area *not* served by Worthing service	603	626	+23 (+*4%*)
Total admissions	1151	850	−301 (−*26%*)

At Summersdale Hospital the impact of the scheme has been even greater (table II), the number of admissions fell by 221 (77%) This has not surprised us, for we have become convinced that if outpatient treatment is available these patients need only exceptionally enter hospital On the other hand, the reduction of 40% in the admission-rate to Graylingwell Hospital was unexpected, for this hospital receives the more advanced and acute mentally ill patients, and we were doubtful whether the service could help them much The reduction, however, has been steadily maintained over the ten months and it seems that an outpatient service can treat even these patients where the background is favourable

TABLE II—ANALYSIS OF ADMISSIONS FROM WORTHING AREA

—	Graylingwell Hospital			Summersdale Hospital			Total		
	M	F	T	M	F	T	M	F	T
1956	108	152	260	69	219	288	177	371	548
1957	69	88	157	22	45	67	91	133	224
Reduction	39	64	103	47	174	221	86	238	324

Elderly patients are especially reluctant to enter hospital and outpatient treatment has proved effective in this important group of patients The number of admissions among elderly patients fell by 55 (51 4%) in 1957 (table III)

The commonest psychiatric illness among these patients is depression. The attack can be severe and often it is the first psychiatric breakdown in a patient with a good stable personality If the condition is diagnosed promptly, suitably modified electrical treatment as an outpatient will bring about a remission But delay in treatment allows time for physical deterioration

TABLE III—ADMISSIONS AMONG ELDERLY PATIENTS

Age	1956	1957	Difference	
65–69	57	20	−37	−55 = 51·4% reduction
70–74	50	32	−18	
75–79	31	18	−13	−24 = 38 7% reduction
80–	31	20	−11	
Total	169	90	−79	= 46 9% reduction

Among patients aged seventy-five and over the admissions fell by 24 (39%), but we adopt a cautious attitude toward this age-group Though the reduction in the admission of elderly patients has been steadily maintained over the past ten months, the admission of senile patients fluctuates widely and the present reduction may be only temporary

Discussion

Our experience at Worthing has convinced us that for a large proportion of psychiatric patients, admission to hospital is unnecessary and outpatient treatment can be entirely effective Indeed, there is much to suggest that our mental hospitals have been carrying an unfair burden by being compelled to treat all types of patients without discrimination It should not be thought, however, that our experience has led us to the conclusion that the mental hospital is an anachronism and redundant indeed our respect for it has increased Now, however, we see it in its true perspective as a hospital for selected patients, mostly with a good prognosis, but needing special treatment and conditions which cannot be provided by an outpatient service

Each of us has had some difficulty in reorienting ourselves to this new form of psychiatric practice We had accepted the idea that it was good for a patient with a mental illness to be removed to the artificial environment of a mental hospital and placed under control before he received treatment In an outpatient treatment service it is never possible to divorce the patient from his family and background, and indeed from his own doctor We ourselves, therefore, have had to make some readjustments

Only a proportion of patients are suitable, and we have come to regard the following basic requirement as essential to successful outpatient treatment

Good Public Relations

The success of a district mental-health service depends on its public having learnt to accept mental illness as it would any other illness and to seek advice and treatment promptly In this respect, West Sussex is probably better off than many other parts of the country For some years frequent talks, followed by visits to the hospital, have been given to many groups of people, and psychiatry and the mental hospital is no longer a mystery Fear of Graylingwell has largely disappeared, as is shown by the fact that of the 1347 patients admitted last year, 85% were either non-statutory or voluntary patients The Worthing service has itself done much already to encourage patients to seek treatment promptly

Cooperative Patients

At the treatment centre and at the clinic we must have full cooperation from the patients Usually this is willingly given, the patient does not want to enter hospital, but he does want treatment Where insight is defective, however, admission to hospital may be necessary if treatment does not quickly bring about noticeable improvement

Favourable Home Background

Our patients are not in hospital under trained observation, but they are at home with their families *Unless the relatives* are prepared to work with us and to accept some responsibility for the patient, the case is unsuitable for outpatient treatment. Usually the relatives are most helpful, but we have to make sure, too, that they themselves are not exposed to unreasonable strain If the pressure becomes too great, the patient must be admitted to hospital

Reasonable Risk

The commonest risk, of course, is that of suicide by a depressed patient. If such a patient is living alone it would be an unreasonable risk to treat him as an outpatient. On the other hand, if there is a favourable background and his history is reassuring, he may well be so treated. Each case must be treated on its own merits, but where there is any real doubt inpatient treatment is necessary.

Risk from a patient acting dangerously towards others is less common, and where such a tendency does exist we advise admission to hospital.

Another risk we have to assess is that arising from the physical condition. A patient may be referred to us suffering from a psychiatric illness which will benefit from treatment, but his physical condition may be such that it would be too risky to treat him as an outpatient.

Effective Range of Treatments

We retain in the Worthing service only those patients who can benefit from the treatments which we are able to offer. In our opinion the clinical results from outpatient treatment are equal to those of hospital treatment. We are unable, however, to provide deep insulin-shock therapy or prefrontal leucotomy and when patients need these forms of treatment we arrange for their immediate admission to hospital.

The medical practitioners have had also to make some readjustments because the procedure for the treatment of psychiatric patients has been changed. Formerly the doctor referred his patient either to the Worthing Hospital outpatient clinic, or, through the duly authorised officer arranged for his immediate admission to hospital. Either way, apart from a psychiatric report, he often lost all personal contact with his patient until he received a second report informing him that the patient was being discharged. Today, for more than half the psychiatric patients in our area, treatment is given on an outpatient basis and the patient remains in the care of his own doctor. In general the new method has been welcomed. The family doctor is now working with the psychiatrist, and, while there must sometimes be difference of opinion, so far we have met no serious difficulties. If a serious difference of opinion should arise, we would leave the final decision to the patient's doctor. We have enjoyed meeting the doctors at the treatment centre or on domiciliary visits, when we are able to have friendly discussions about the diagnosis and treatment of their cases. Though formal reports are still necessary, this constant personal contact with the patient, his family and background, and his own doctor has offered us conditions which make possible the practice of individual psychiatry—the ideal of every psychiatrist.

The effect of the district service on Graylingwell Hospital is already noticeable. The fall in admissions has considerably eased overcrowding. This, we believe, could be entirely removed by the provision of outpatient treatment services in the rest of the hospital's catchment area which is now under consideration.

Conclusion

The Worthing and District Mental Health Service is a two-year pilot experiment. It is essentially a research project, for this service is the first of its kind to be undertaken by a county mental hospital. It has been in operation only ten months. In our opinion, however, we already possess sufficient evidence to prove that such an outpatient service can do much to ease the strain on the mental hospital, and this was the object for which it was designed.

The Worthing service has revealed many aspects of clinical psychiatry which could be the subject of fascinating research for many years to come. Even at this early stage however, it may also be indicating a blueprint for future psychiatric practice: each catchment area will have at its centre an efficient mental hospital, with satellite outpatient treatment services which ensure that only those patients are sent into hospital who really need to be there.

HIGHER EDUCATION IN AUSTRALIA

FROM AN AUSTRALIAN CORRESPONDENT

Since the war, Australia has become one of the most rapidly expanding countries in the world. The population has grown at a rate of 2½% per annum over the past ten years, and there has been an equally startling growth of secondary industry, supported by a steady advance in primary production. At the same time Australia has come to play a much greater part in the political and economic affairs of South East Asia and the world at large. It follows that in the future she will require an increasing supply of university graduates to meet her professional, cultural, and technological needs.

In 1956 Mr Menzies invited a committee, headed by Sir Keith Murray, chairman of the University Grants Committee in Britain, to investigate the position of the Australian universities and to suggest how these could best play their part in the development of the country. This committee's report shows a disquieting situation. Far from being ready to meet the immense future demands upon them, the universities of Australia are evidently tending to stumble under the burden of their present reponsibilities.

DIFFICULTIES OF AUSTRALIAN UNIVERSITIES

Their peculiar difficulties are often insufficiently appreciated outside Australia, and indeed have scarcely been realised by a majority of Australians. There are nine universities and two university colleges. Apart from the postgraduate National University at Canberra, which is a Commonwealth affair, the major universities are primarily the responsibilities of the States in which they operate, and so far New South Wales is the only State which has more than one. It is thus inevitable that regional problems should arise. The economies of the States vary widely, and the facilities and finances of the State universities are far from comparable. Nevertheless, many difficulties are common to all Australian universities, and the committee has considered some of these at length.

The basic problem is the weight of student numbers, particularly in the first year.

The Australian universities have set their faces against any form of pre-selection of students, and in consequence everyone who can pass the matriculation examination is automatically admitted to the first year in the faculty of his choice. The pressure is perhaps greatest in the departments of physics, chemistry, and mathematics, which provide the basis of so many professional curricula, but many arts departments are almost as badly affected.

Where classes are 800 strong and practical work is replicated in six or seven sessions, the individual is necessarily submerged, and it is almost impossible to organise the personal attention which is one of the most important things a university can offer. There is an appallingly high failure-rate in the first year, and the student comes to regard the examination as the chief motivation for his efforts. The attitude so acquired is unfortunately difficult to eradicate in the later stages of his education, when the desperate struggle for survival has abated somewhat.

At some universities very many part-time and external students are enrolled. Because of the awkward requirements of laboratory and practical work, such students are found in greatest numbers in the faculties of arts, where they create special difficulties For example, a great deal of teaching has to be done in the evenings, and lectures and seminars have to be duplicated

Yet the principle of unrestricted entry is deeply ingrained by tradition The previous educational experiences of matriculants are so varied that it is thought essential to give them all a chance under identical conditions before presuming to choose which of them are fitted to continue their education further Indeed, the committee, after considering the situation carefully, did not suggest any modification of this admissions policy

TEACHERS AND BUILDINGS

If student numbers are not restricted, efficient and meaningful education can be provided only where accommodation, equipment, and staffing are adequate, and in these respects the situation appears not only alarming but critical

In most universities "temporary" buildings have been put up in an attempt at expansion, like all temporary buildings they have become permanent in an unpleasant sort of way, and a secondary growth of further "temporary" accommodation has sprung up around them

This situation arises partly because the universities live under an administrative system which does not allow them financial security for more than a year ahead Anything beyond ad-hoc planning is thus a desperate venture Little has been done for many science departments since the day they were first equipped, and laboratories are often woefully ill-matched to the tasks now laid upon them

Even more important is the difficulty of attracting and keeping staff of the requisite high quality, particularly in the sciences The salaries paid are grossly out of line with the corresponding salaries in industry or in such bodies as the Commonwealth Scientific and Industrial Research Organisation, and superannuation conditions in many universities are unsatisfactory Australian universities are also rendered unattractive by their isolation, both from each other and from the rest of the world As the committee point out, Perth is as far from Sydney as London is from Istanbul To make such conditions acceptable to the right sort of candidate it is therefore necessary to have not only competitive salaries and terms of employment but also well-organised and well-financed schemes of study-leave and travel

The lack of adequate staff is one cause of the scarcity of honours and postgraduate students, which is a serious omen for the future Concentration on the pass degree as the chief end of education means that most Australian students of above average ability go elsewhere to complete their honours courses, and are often lost to the country

These disabilities have a readily understandable immediate cause—lack of money Enough money, wisely applied, could transform the situation as regards accommodation and staff The reason for the lack of money is also not hard to discover Quite simply, the average Australian is not preoccupied with education He has as yet little conception of the vital part the universities must play in the economy of his country, and the universities themselves have done little to make the situation clear to the public

With time this lack of interest in the universities will right itself, but time is short If the universities cannot cope with their present problems, how can they deal with the appalling overload they face in ten years' time? In 1967 the university student population is expected to be more than double that of 1957, and the prospect calls for immediate action

RECOMMENDATIONS

The committee have made a number of recommendations designed to remedy the present disabilities and to render the universities fit for their future task

The most important recommendation is the creation of a University Grants Committee on the lines of the British one This would consist of a full-time chairman and seven part time members and would function as an informal body without legislated status Two members would be drawn from the professions or industry, and the remaining five would be academic members covering the five main groupings of arts, social sciences, pure sciences, applied sciences, and medicine and dentistry Grants for recurrent expenditure would be made triennially, and would not be earmarked for particular purposes On the other hand, non-recurrent grants would be given annually, and for specific purposes only

The committee have recommended an extensive programme of financial first-aid for the next three years, while the University Grants Committee is finding its feet They suggest that a total sum of nearly £A12½ million should be devoted to building programmes in the various universities, and that the Commonwealth Government should contribute towards these on an equal financial basis with the States, except that in Western Australia and Tasmania the Commonwealth contribution should be 25s for every £1 spent by the State About another £A1 million should be spent on equipping these buildings, and the Commonwealth Government should contribute 16% of this sum An immediate increase in academic salaries is recommended, the rise being at least £A500 for professors and corresponding amounts for other posts There should be an examination of the conditions of service to see how these might be made more attractive

The committee recommend the creation of a new university in Melbourne to serve the needs of Victoria This university would contain a medical faculty, which would ease the pressure on the present university and ensure an increased supply of doctors to a State whose medical requirements are said to be far from satisfied The committee also suggest the creation of another medical school in New South Wales, possibly in relation to the New South Wales University of Technology The medical school at Sydney has been dealing with vast numbers for many years, and this plan would undoubtedly help matters, though, as the committee suggest, it might be necessary to change the name of the University of Technology to avoid the implication that its medical graduates are technologists Tasmania submitted a claim that the committee should consider the founding of a third medical school there, but in the opinion of the committee Tasmania cannot afford a medical school until the present disabilities of the university have been put right It did, however, recommend the development there of a faculty of agriculture Tasmania is now the only State without a medical school, for the medical school of the University of Western Australia began operations this year It is to be hoped that the unsatisfied aspirations of potential Tasmanian doctors will be met by the creation of the second medical school in Melbourne

The Commonwealth Government has already accepted these proposals But the detailed planning and development of individual universities is, as Mr Menzies has said, a matter for the States, and these have not yet pronounced on the report It is expected that they will implement at least the building part of the committee's proposals, but clearly this will be of little use unless they also accept the salary increases and the other suggestions about the employment of university staff

This historic report should mark the beginning of a new deal for the Australian universities and of recognition by the average Australian that he has in higher education not only an invaluable tool and a vital safeguard to his country's future, but also a priceless and irreplaceable cultural asset

Points of View

DISAPPOINTMENTS IN DERMATOLOGY*

R. E. Bowers
M.D., B.Sc. Lond., M.R.C.P.
DERMATOLOGIST, NORTH GLOUCESTERSHIRE AREA

Some claim that they can recognise a consultant's specialty at sight, and I am told that the gynæcologist, neurologist, pathologist, and ophthalmologist present little difficulty to the initiated. To identify a solitary dermatologist might be less easy, but on his way to a consultation he can always be recognised by the expression of anxiety on the face of the practitioner who has called him out. My object here is to examine some of the reasons for this unhappy state of affairs, and to illustrate them from a few everyday problems

* * *

The first skin clinic I attended as a student—it was also the last—was puzzling I recollect a kindly physician who fingered the most alarming lesions, and then ran his hands over his face and through his hair These lesions bore incomprehensible names, and so did the remedies applied to them, my pathology and pharmacology textbooks had not mentioned them One particularly nasty sight was recommended to me thus "Take a good look at this, you'll never see another" This seemed strange, I was even more puzzled when the next patient proved to have the same disease

The outbreak of war brought these undergraduate studies to a premature close; but I still remember the frustration of those few hours, and many of us must have had a similar experience which has determined our subsequent attitude to the whole subject It has made us view dermatology as a study apart from the rest of medicine having neither pathology nor therapy, beginning nor end.

An eminent pathologist has defined a hæmatologist as a man who makes a living by applying a series of different names to a succession of identical blue globules An existence spent in the dubious differentiation of a succession of identical pink papules is all that is accorded in many circles to the dermatologist. Yet in most skin diseases, a careful history, a careful examination, and a considered diagnosis are as vital as in the rest of medicine

Samuel Butler said that life is the art of drawing sufficient conclusions from insufficient premises but there is no point in neglecting our premises altogether The careful history and examination are never wasted, even if they do not give the answer, and you have to refer the patient to a dermatologist who makes a diagnosis of Pityriasis Lichenoides et varioliformis Acuta, your attention will have assured the patient that you are interested in him, and will give him confidence while you see him through the course of this disease, which may last for months, is not influenced by treatment, and is of unknown ætiology

* * *

Let us imagine that we are confronted by a patient with a rash. At sight we can make a diagnosis of eczema, which statistically is bound to be correct nine times out of ten, or of dermatitis, which is the same thing for all practical purposes except in a court of law But before we can attempt to treat the patient we must make an ætiological diagnosis too

Here lies one of the difficulties on the hands it might look the same, whether caused by 'Dettol,' diesel oil, 'Distaquaine' or divorce, on the face almost identical appearances may be given by sensitivity to cosmetics, chrome salts, or just conscience. Moreover, there may be multiple factors, a nurse may not show her sensitivity to streptomycin until she has some emotional upset, and her cure will involve mental readjustment as well as avoidance of the offending drug But a clinical and environmental history will usually sort out these possibilities, for instance, sudden relapses and good remissions, particularly on exposed parts, point to contact dermatitis, perhaps from cosmetics or other chemicals, a chronic course, especially with a family history of eczema, asthma, or hayfever, makes one suspect a constitutional eczema.

Remember that it is not necessarily an expression of defeat to diagnose constitutional eczema· the diagnosis is often made for sound reasons, in the same way as one detects a constitutional asthma And just as one tells an asthmatic to avoid murky and dusty atmospheres, so one may ask people with inborn eczema to avoid wet or dirty employment without meaning that their eczema was initiated by such work.

Now comes the next cause of disappointment. we have obtained a fair idea of the diagnosis from the history and appearance of the presenting lesion we become bold, and neglect to make a thorough examination of the patient. This is a very risky short cut. For example it can be very humiliating to have your case of "? varicose eczema with œdema" returned to you for treatment of his heart-failure.

Sometimes the patient makes mistakes—often deliberate—about the distribution of his lesions, or he may fail to mention that patch of psoriasis on his abdomen which would give us the clue to his extremely scurfy scalp, or he may be satisfied in his own mind that his broad syphilitic condylomata are really piles, and that this is neither the time nor the place to discuss anything except his distressing and abrupt loss of hair Or perhaps the old lady may be concealing huge chronic leg ulcers, they are being treated by her kindly neighbour with some penicillin cream, so that what presents to you as an eczema of the face is really a sensitisation-eruption

Here I should like to pause for a while to consider the phenomenon of sensitisation, or allergy if you prefer it, as applied to the skin. It is easy to understand how a chemical such as caustic soda or turpentine can cause inflammation after only one or two contacts This is called primary irritation, it is easily recognised, easily avoided, and often correctly diagnosed by the patient.

But the idea of secondary irritation, or sensitisation, is much more difficult

In this case we are dealing with a comparable inflammatory response, but it is one which appears only after repeated contact with something which is not necessarily a primary irritant, even in heavy concentrations The acute eczema which may result from repeated contact with primulas is one of the most familiar examples of this, but the number of potential sensitisers is almost infinite They may be very hard to suspect, for the patient, once sensitised, may react to minute concentrations, and the cause may be some old and trusted friend such as a cosmetic which was thought to be vital to the continued integrity of the skin. I have heard quoted the case of a lady who developed patches of intractable eczema over the face and sternum, she was known to be sensitive to black hair dyes, but all attempts at ætiological diagnosis were foiled until it was observed that one of her male friends had a suspiciously black moustache.

Most of the remarks I have made so far apply with particular force to the difficulty of diagnosing occupational eczema; but I think the frustration which most of us have experienced in dealing with occupational dermatitis merits rather special examination

---

* Based on a paper read to the North Gloucestershire branch of the British Medical Association, in April, 1956

The problem is complicated by its relationship with the Law For reasons which are no longer valid, a man disabled by eczema gets more sick pay if it is attributed to his work than if it is idiopathic To decide which it shall be is almost as difficult as to use the McNaughten rules, and the effects of the decision may be almost as disabling, even if somewhat less spectacular

It is a curious paradox that the more sane a murderer appears to be, the greater is everyone's wish to prove him mad so that he may escape the worst penalties In the same contrary manner, the more chronic and disabling, and hence the more idiopathic, the patient's dermatosis, the greater is everyone's *natural desire to call it occupational*, and thus to mitigate his poverty But its persistence through months or years of idleness is really one of the strongest possible pieces of evidence against its occupational origin

I do not deny that true cases of dermatitis from primary or secondary irritants arise in industry these are comparatively easy to recognise, and to confirm by patch testing they subside soon after the patient stops work, and do not return when he goes back to work away from the suspected chemical But unfortunately such cases are a minority, in the majority of those that I see, all the medical probability is against an occupational cause, *and in favour of a constitutional origin*, with or without a psychological overlay But medical probability is a very different thing from legal possibility, and where the possibility exists, we incline to give our patient the so-called benefit of the doubt and to allow him his compensation The position is especially difficult where a constitutional predisposition seems to have been touched off by an occupational factor

The subsequent history of such patients can be very depressing Their eczema, being wholly or largely constitutional, might in any case persist for a long time, their natural desire to blame somebody for it is focused by our certificate on to their employers, and some degree of neurosis is almost bound to develop, especially in those who are maladjusted, or unhappy at home or in their work

In such cases a solicitor may be consulted at this stage, and *the probable results are so well known to most of us that they* need no further elaboration The dreary medical examinations, the dreary days in court, the expert witness obliged to admit that the dermatosis might be attributable to the occupation, and the final state of pensionable unemployability and pruritus, would all have inspired Dickens to great heights, if only the compensation laws had reached their present pitch of perfection in his day

It is therefore unfortunate that, as the Law stands, we may well be forced into certifying that the patient has a legal possibility, against the weight of the medical evidence We may have to do it, but we should realise what we are doing, and try to make it clear to the patient and his relatives

In the long run, the only way out of this difficulty is to get the compensation rates altered—to abolish the illogical difference between the rates for sickness and occupational dermatitis Cases of genuine occupational dermatitis could then be determined on reasonable medical grounds , they should be made notifiable to the factory inspectors or public-health authorities, whose duty it would be to investigate the working conditions, with the *dermatologist's help* if required, and to advise suitable precautions to prevent similar cases The patient's right to a common-law action on the grounds of negligence would remain unchanged, but there would be fewer initial stimuli to such an action The money saved could be devoted to retraining eczematous patients in work where their eczema was not a grave handicap

* * *

But enough of this theorising, practical men such as ourselves want to know what therapy is available Disraeli defined a practical man as one who practises th blunders of his predecessors , and dermatological literature is full of blunders which we can detect in the light of modern knowledge They nearly all have one facto in common—namely, overtreatment

An example of heroic treatment, which no doubt seemed perfectly reasonable when it was suggested, is contained in Radcliffe Crocker's *Textbook of Diseases of the Skin*, in recommending the use of thyroid extract in psoriasis, he writes

> "The dose should not be more than five grains a day *to begin with*, which in a week may be increased to ten grains and in a fortnight to fifteen grains *if* it is well borne, five grain tabloids are the mos convenient form of giving it The risk of disagreeable symptoms is out of proportion to the advantage of taking larger doses, which should never be given unless the patient is in bed and under supervision Bramwell, however, got up to forty tabloids a day Headache, sleeplessness or giddiness, and the pulse rising over a 100, should be the signal to stop it or to diminish the dose Patients get thinner while taking it Less frequent symptoms are nausea, vomiting, failure of breath, diarrhœa, and general rheumatic pains "

That was in 1905, but the contemporary scene gives little cause for complacency, and the road we have travelled over the past few years is strewn with discarded remedies, some harmful, some harmless, and nearly all very expensive Yet we continue to believe in miracles when rest and other *inoffensive remedies are far more likely to be successful*

In this realm many of our disappointments are the result of a mutual misunderstanding between ourselves and the drug firms When introducing a new therapeutic substance to the profession in general, it is occasionally possible for the manufacturer to cite reports of full convincing trials taken from the pages of a reputable journal, it is reasonable for such a drug to be brought to the practitioner's notice, and little harm follows provided that the possible toxic effects are emphasised to him But often *the samples dispensed and the literature provided should* imply no more than an invitation to practitioners to cooperate in a careful clinical trial, and to use new remedies from the makers on any other basis would do discredit to the outpatient department of an animal hospital In dermatology it is the cause of many sensitisation reactions and of much disappointment to all concerned

It happens for two reasons the first is that we may not have time to demand to see full reports of thorough clinical trials which may or may not have been performed the second is that our patients with eczema include a high proportion of chronic cases They are abnormally likely to react swiftly and unfavourably to local applications, they are the type of patient who is unlikely to have been included in a short clinical trial Patients with chronic eczema are not necessarily curable it is not kind to give them repeated disappointments, it is less than *kind to give them repeated attacks* of contact eczema, which can only make them worse in the long run

Virtually all the true contact eczemas are *self-limiting*, and many other forms of eczema tend to undergo spontaneous improvement if the patient can have physical and mental rest One of the commonest disappointments arises from neglect of this fact, we try to take short cuts Rest in bed, oily or watery calamine to taste, and heav sedation if necessary, are far more effective than an uncontrolled resort to the remedies on our *blotting-paper* The skin cannot be bludgeoned into healing, even by hydrocortisone it is a very mischievous animal—*when it is attacked*, it defends itself A skin which has produced an eczema is already in a state of turmoil, it is very likely to become sensitised to almost any local application, and must be treated with the utmost respect

* * *

One of the most urgent symptoms in dermatology is hing, and the preparations which claim to relieve this mptom give us many disappointments The antiuritics of the -caine group are some of the most noxious nchocaine, amethocaine, benzocaine, and a number of milar substances have no place as local applications in zema, they are potent sensitisers, and they distract tention from the fundamentals of treatment, if by any ance they should appear to give temporary relief

In the same category come the anti-histamine ointents, which have no curative effect on the eczemas, and hose antipruritic action should be reserved for insect tes They are only weak antipruritics but they are werful sensitisers

If a patient's itch is severe enough to demand these cal antipruritics, then what he really needs is rest and dation, if he gets unduly clamorous, then it is possible at he is mentally ill and that he needs expert psychiatric well as physical treatment The really bad case of zema, with gross œdema, generalised weeping, and vere exfoliation, is fortunately becoming rarer now at syphilis is being treated without arsenic, and gold being recognised by the rheumatologists as one of the aser metals, but such patients can usually be relieved ramatically by the use of systemic cortisone or corticorophin I mention this parenthetically, lest anyone hould think that I am advocating a policy of masterly nactivity, even in these severe cases , their active treatnent is anything but disappointing

The administration of anti-histamines by mouth calls or some consideration, for it has been strongly advocated n the eczemas

One may say at once that it does not fall into the same reprehensible category as the topical application of the same substances, but unfortunately the anti-histamines have no specific effect on eczemas however they are given Their sedative action may be useful, but similar effects can be obtained at a fraction of the cost by the use of barbiturates, chloral, or bromides In this connection it is worth noting that quite heroic doses of sedative may be needed for instance, a husky man or hysterical woman with eczema can often take sodium barbitone gr 10–15, or a corresponding dose of amylobarbitone, four or five times daily for some days before severe drowsiness supervenes

At this point many will register strong disagreement they have seen dramatic relief from the oral use of anti-histamines in eczema I agree with this, it comes about in this way eczematous people tend to have other allergic diseases, including urticaria, the wealing in urticaria can often be produced by damage to the skin, so a potentially urticarial subject who gets eczema may also have an urticaria, brought forth by each eczematous lesion, and by scratching Therefore anti-histamines, which we all agree are effective in urticaria, are well worth giving by mouth in this sort of eczema, where we can see wealing

But these are all rather minor details Our patients may disappoint us, and be disappointed, for more general reasons

First and foremost is the fact that skin lesions are visible, therefore more than ordinary powers of persuasion are needed to delude the patient into thinking he is cured if he isn't Moreover, it is impossible to prevent his relatives, neighbours, and factory ambulance man from trying their hand at treatment, which makes our task very difficult

Acting in the part of Cleopatra, Sarah Bernhardt stabbed the slave who bore to her the tidings of Mark Antony's defeat at Actium, she stormed, raved, wrecked some of the scenery in her frenzy, and finally, as the curtain fell, dropped in a shuddering convulsive heap As the applause died, a middle-aged British matron was heard to say to her neighbour "How different, how very different from the home life of our own dear Queen" It is well to remember that the patient's life is different from ours he has not seen many dermatoses, and he and his friends fear them all In virtually every case of eczema one must give an assurance that it is not infectious, and that it must not be subjected to homely therapeutic trials, and sometimes one should say specifically that it is nobody's fault, or even that it is not a venereal disease These small assurances may save us from the frustration of attending a patient who seems to fear us what he really fears is that we may have discovered something about his past, and that we won't tell him

Lastly, unlike the general physicians, when we have failed to cure our patient, we cannot hand him to the surgeons for removal of the offending organ with the confident, cheerful, and very truthful assurance that he will be made worse before he is better

It is often asserted that skin patients never get better, that they never die, and that the dermatologist never gets up at night In defence of my craft, I can only plead that we have no monopoly of incurable patients, and that their immortality must do us credit Getting up at night we regard only as a distressing symptom needing skilled investigation we are proud and thankful that we do not suffer from it

I am very grateful to Dr H J Wallace and to the late Dr J M Ellis for invaluable help in the preparation of this paper

Conferences

LIVER DISEASE

THE annual meeting of the American Association for the Study of Liver Disease was held in Chicago on Oct 31, with Dr G KLATSKIN (Yale) in the chair

Acute Hepatic Necrosis

Prof HEINZ KALK (Kassel, Germany) described a biopsy study begun in 1923 The first needle biopsy was made in 1934, and since then 4134 had been done, mostly under direct vision More recently the liver had been photographed through the peritoneoscope Professor Kalk emphasised the advantage of biopsy under direct visual control, blind biopsy might miss patchy or localised lesions

He had seen more than 90 patients in hepatic coma Most of them, unlike those in American and most British series, had acute hepatic necrosis, in 3 rather unusual cases, studied two, four, and six weeks after an episode of coma, the liver was normal On the other hand he had also seen some patients whose livers showed scars of a preceding necrosis, but who gave no history of such an illness, this patchy scarring might easily be missed by blind biopsy Such " scar " or " potato " liver was often associated with normal liver-function tests These " scar " livers he believed to be clinically distinguishable from " cirrhosis ", but by biopsy alone the distinction was not always easy In the acute stage of necrosis the liver was red and swollen with a rounded edge, later, scars appeared and in time became pale and shrunken, the surrounding liver remaining brownish In his experience the left lobe was almost always more severely affected than the right, after recovery the right lobe might hypertrophy and overgrow an atrophic left lobe In time necrotic tissue was replaced by non-specific granulation tissue, scarring resulted if the reticulin framework was destroyed, as the lobular architecture could not be replaced Fibroblasts were then replaced by "scar" tissue, and the deeply grooved " potato ", or " scar ", liver resulted

Once the episode of acute necrosis was past the prognosis was good, though transitory ascites might arise at four to six weeks The real danger facing these patients was not progressive liver-failure but portal hypertension, fortunately they were particularly suitable for shunt surgery In some patients a mixed lesion of " scar liver and cirrhosis " developed, and in these the prognosis was bad, the common end-result being hepatic coma

Some patients had repeated small episodes of necrosis and scarring, leading to a final picture almost indistinguishable from Laennec's cirrhosis In cirrhosis, however, he believed that the initial lesion was inflammation of the supporting-tissue at the periphery of the lobules, leading to secondary death of the parenchymal cells and a uniform, fine granulation In acute necrosis, on the other hand, the primary lesion was death of the parenchymal cells in the centre of the liver lobules, followed by secondary scarring

Cholestatic Jaundice

Dr F W Hoffbauer (Minneapolis) suggested that there could be no hard-and-fast rule as to whether cholangiography was necessary in the diagnosis of intrahepatic cholestatic jaundice (I H C J) If surgical assistance was decided on, he favoured a very limited incision under local anæsthesia, and cholangiography A decision whether or not to proceed to laparotomy should be made in the light of the radiographic findings Biopsy specimens must be taken from the liver at the beginning, not the end, of operation to avoid the histological appearance of " retractor hepatitis "

Secretion of Bile

Dr R W Brauer (San Francisco) believed that bile was actively secreted by the parenchymal cells of the liver The concentration of electrolytes was about the same in the bile as in the blood, but the concentration of bile-pigments and bile-salts was much greater in the bile than in the blood, and there were also more complicated molecules present, such as alkaline phosphatase and mucins The bile canaliculi, he considered, did not behave like the renal tubules—i e , they did not concentrate or actively secrete into the bile—but they did permit equilibration between capillary blood and bile so that small molecules such as water, salts, and glucose could move freely from bile to blood or in the reverse direction Dr Brauer concluded that in I H C J the primary lesion was in the membrane dividing the liver-cells from the bile canaliculi Differential diagnosis from main-duct obstruction was difficult

Dr H E MacMahon (Boston) thought that a definition of I H C J must include all cases with jaundice with no mechanical obstruction of the main bile-ducts and no active hepatic necrosis, and should exclude cases of Laennec's cirrhosis This was not a disease entity but a syndrome comprising different conditions Histologically there were two distinct stages at first the bile-ducts proliferated, later they tended to become scarce and might even disappear altogether, as he had seen following the administration of chlorpromazine The histological picture of I H C J could result from main-duct obstruction, besides cholangitis, cholangiolitis (or primary biliary cirrhosis), acholangitic jaundice, fibroxanthomatous jaundice, mucoviscidosis, occasionally carcinomatous and Laennec's cirrhosis, and hæmachromatosis Clearly the histological diagnosis was difficult and could not be made by the pathologist alone

Professor Kalk said that in the initial stages of I H C J inflammation was conspicuously absent, and he preferred to call the condition a hepatosis

Bile-duct Atresia

Dr R C Harris (New York) had studied by serial biopsy 7 patients with intrahepatic bile-duct atresia At birth the atresia was not complete, but by 2 years all bile-ducts had disappeared Clinically these 7 cases fell into two groups In 4 the course was of long-continued obstructive jaundice, and hypersplenism developed The other 3 cases were more typical of cholangiolitis, and the blood-cholesterol levels were very high Histologically there was little fibrous tissue in the portal tracts This was either a disease of the ductules or possibly a metabolic error, perhaps similar to galactosæmia

Aldosterone in Cirrhosis

Dr J M Stormont, Dr S J Wolfe, Dr B Fast, Dr J Crabbe, and Dr C S Davidson (Boston) had found that patients with cirrhosis had a high urinary excretion of aldosterone compared with normals, but not higher than normals on a low-sodium diet Amphenone was given in an attempt to inhibit aldosterone secretion This drug produced mental changes similar to those in impending hepatic coma, but did not reproduce the typical electroencephalographic changes Some protection against this side-effect was obtained by the simultaneous administration of prednisone In 2 out of 4 patients the secretion of aldosterone was blocked, with consequent sodium diuresis, the other 2 patients did not respond, suggesting that other factors were involved in sodium retention in hepatic cirrhosis

Hepatosplenography

Dr J G Teplick and Dr J E Berk (Philadelphia) discussed attempts to find a non-toxic medium for hepatosplenography Barium sulphate given intravenously to rabbits and dogs outlined the liver and spleen clearly in two hours but could be readily detected in the reticulo-endothelial cells eighteen months later Iodised oil 45%, emulsified in water with 'Tween 80', was also given intravenously to laboratory animals, this outlined the liver and spleen in about two hours and was clearing by five days Toxic reactions were observed, though these were mostly minor and transient If a smaller particle emulsion (10–100 μ) could be prepared this might be a safe contrast medium for intravenous use

Portal Hypertension

Dr C M Leevy and Dr M L Gleidman (Jersey City) had studied patients with portal hypertension by means of liver biopsy and measurement of the wedged hepatic-vein pressure before and after medical treatment Portal hypertension arising in the course of hepatitis and fatty liver responded rapidly, and œsophageal varices regressed as fat was mobilised from the liver Corresponding with this there was an increase in the hepatic blood-flow In patients with active cirrhosis the pressure might fall to normal and varices disappear, but not all patients showed this improvement and those who did not should be offered a portacaval shunt

Wilson's Disease

Dr J M Walshe and Mr S B Osborn (London) reported their work with radioactive copper in Wilson's disease Their results showed that penicillamine mobilised copper more powerfully than dimercaprol, that a normal person concentrated copper in the liver faster than patients with Wilson's disease, and that the specific activity of the urine copper fell sharply in the normal about the time cœruloplasmin-bound copper appeared in the circulation

Dr I H Scheinberg (New York) agreed that penicillamine was an extremely powerful " decoppering " agent, but its activity appeared to fall off after several months of continuous administration He had treated 4 patients with it for nearly a year, and 2 had done well

Liver-function Tests

Dr G M Mindrum and Dr H I Glueck (Cincinnati) reported that in most patients with cirrhosis and many with hepatitis the concentrations of factors V and VII were reduced, even when the prothrombin level, estimated by the one-stage method, was normal In patients with severe cirrhosis and, temporarily, in patients with hepatitis the prothrombin level was often less than 50% of normal and did not respond to parenteral vitamin K Using a two-stage assay for measuring " true " prothrombin, these workers found that this was an excellent prognostic test, especially if the two-hour response to vitamin K was measured The test was not influenced by variations in the levels of factors V and VII

Dr K S Henley, Dr H S Wiggins, Prof H M Pollard, and Dr E Dullaert (Ann Arbor) had estimated the transaminase content of parenchymal liver-cells They made a suspension of parenchymal cells in citrate and estimated the levels of glutamic-oxaloacetic transaminase (G O T) and glutamic-pyruvic transaminase (G.P.T.). They found that the G.O.T. was mostly retained in the cells, while G.P.T. escaped into the suspending medium. This correlated well with the clinical observation that estimation of G.P.T. was a better index of liver injury than estimation of G.O.T.

Dr C. L. STERKEL, Dr J. A. SPENCER, Dr S. K. WOLFSON, and Dr H. G. WILLIAMS-ASHMAN (Chicago) had studied serum-isocitric-dehydrogenase (I.C.D.) levels in patients with liver disease and compared these with serum levels of G.P.T. and lactic dehydrogenase (L.D.). In patients with acute hepatitis, the serum-I.C.D. was much increased; this increase was not found in other forms of hepatic disease except cases of extensive carcinomatous infiltration of the liver. With recovery the serum-I.C.D. returned to normal. The serum levels of L.D. followed no such consistent pattern. The G.P.T. was also increased in acute hepatitis only, and returned to normal with recovery. The advantage of the I.C.D. determination was that it was easier and more specific for liver damage; the level had proved to be normal in 250 other patients with a wide variety of disease-states.

Medicine and the Law

The N.H.S. Tribunal

SOME interesting, and on the whole encouraging, facts are given in the report of the chairman of the National Health Service Tribunal for the three years ending six months ago.

The tribunal's main function is to consider representations that the continued inclusion of a practitioner—i.e., doctor, dentist, chemist, or optician—in the appropriate list would be prejudicial to the efficiency of the service. It also has the secondary function of considering applications for reinstatement.

During the three years 13 new cases arose in which it was asked to direct the removal of a practitioner from the appropriate list, and all 13 requests came from executive councils. In addition, it received 8 applications for reinstatement. This total of 21 cases compares with 33 for the period 1948–51 and 29 in 1951–54.

The total number of cases actually dealt with by the tribunal in 1954–57 was 23: some had been carried forward from the previous triennium, and some had not been finally disposed of by July 4, 1957. In 6 cases, the tribunal directed the removal of the practitioner's name from the list, but in 5 others the case was withdrawn on the practitioner undertaking not to practise under the N.H.S. There was only one appeal to the Minister, and that failed.

The 6 cases in which the tribunal directed the removal of a practitioner's name included 3 doctors.

The chairman, Sir Reginald Sharpe, Q.C., welcomes two recommendations of the Franks Committee on Administrative Tribunals and Inquiries. These are that the right of the practitioner to appeal from the tribunal to the Minister should be abolished, and that the appeal from the decision of the executive council in minor cases should lie to the tribunal instead of to the Minister as at present. This latter recommendation, if put into effect, will much increase the tribunal's work: between 1950 and 1954, the number of appeals from executive councils to the Minister averaged 125 yearly. The addition of this amount of work would clearly make the tribunal much less of a part-time body than at present, but on the whole it seems preferable that such appeals should be dealt with by a properly constituted tribunal with recognised rules of procedure rather than by an official of the Ministry, however capable and impartial.

Sudden Illness and Dangerous Driving

At 10.45 one evening, a man drove his motor-van across a road junction at a fast speed and came into collision with a car. The van then carried on for a short distance and overturned. On a charge of dangerous driving the defendant contended that he became unconscious as a result of being overcome by a sudden illness and that he was not therefore liable at criminal law. The Justices found that the defendant must have exercised skill in driving in order to reach the road junction, but they were of opinion that by the time he reached that point he was not capable of forming any intention as to his manner of driving, and they dismissed the charge. The prosecutor appealed.

The LORD CHIEF JUSTICE, giving judgment, said that the Road Traffic Act, 1930, contained an absolute prohibition against driving dangerously and no question of intention entered into the offence. The Justices probably meant that the defendant was in a state of automatism, but the defendant's evidence was consistent with his being overcome with sleep and falling asleep was not a defence to dangerous driving. There was no evidence that he was suffering from anything amounting to a "blackout" nor that he had ever had such an attack before. Accordingly, the appeal would be allowed.

Mr JUSTICE DEVLIN, agreeing, said that if the onus lay on the defence to produce some evidence of automatism, they had failed to do so, with the result that the Justices had come to a wrong conclusion in law. The defendant had not set up a defence of insanity, and unless there was evidence which showed that his irrationality was due to some cause other than disease of the mind the Justices were not entitled simply to acquit.

Mr JUSTICE PEARSON, agreeing, said that if the defendant was driving at all he was driving dangerously; therefore the question was whether he was driving. Normally, a person in the driving-seat of a car was, prima facie, driving unless there was evidence to show that he was rendered unconscious or otherwise incapacitated from driving the car. For example, the person has an epileptic fit or is reduced to a state of coma or is completely unconscious through the onset of some disease, or he is stunned by a blow on the head by a stone thrown up from the road, or he is attacked by a swarm of bees, so that he is prevented from exercising any directional control over the car. In each case he would not be driving. If a man falls asleep in the driving-seat, after he has fallen asleep he is no longer driving, but at the point at which he is falling asleep he is failing to perform a driver's elementary duty of keeping himself awake and so is driving dangerously. Similarly, if a man knows he is liable to have an epileptic fit, but nevertheless drives, it is a question of fact whether driving, in the circumstances, could be considered dangerous. The answer might depend on the degree and frequency of the epilepsy. Here there was evidence that the defendant was driving, and if the burden of proof was on the defence they failed to prove an extraordinary mischance rendering it impossible for the defendant to control the car or direct its movement.

In England Now

A Running Commentary by Peripatetic Correspondents

Now is the time for all fat men (and women) to come for the aid of their doctor Having clambered on and off their weighing-machines with wheezings of *horror*, *gastronomic* recidivists occupy most of one's after-Christmas consulting-room space and time decrying the injustice of the Great Scheme of Things

A doctor whose lunch has consisted of answering the telephone through a mouthful of antacid tablets is tempted to be cool with these beach-ball-like malcontents who plough through the menu sideways as well as downwards, and yet swear by all their Metabolites that they eat nothing at mealtimes and less than that in between After these unlikely and interminable affirmations they depart, their toffee-papers *drifting after them like autumn leaves behind a bus, while the* exhausted physician remembers wistfully 'Fatty' Cortez, who, stout as he was, at least stood silent on top of his peak in Darien—if only because he was out of breath

The treatment of such aggrieved and adipose clients varies, because if the doctor is himself dyspeptic or recovering from seasonal roisterings, the patient is liable to collect a diet that would make a hunger-striker feel he was outraging the Sumptuary Laws (More subtle is the prescription of a menu so recherché that an import licence becomes necessary and the foodstuffs so abominably expensive that the patient loses weight worrying how to pay for them) It should be remembered that patients also lose weight if their food is rendered inedible, and it is not difficult to suggest to them an itinerary which includes hotels whose cooperation in this respect can be relied upon

I remember a squadron mess in 1946 where for this reason we all lost considerable weight, and the mess secretary's solution was to engage a civilian who claimed to have been cook to Field-Marshal Montgomery Twenty-four hours and an attack of gastroenteritis later he confessed that *his* Field-Marshal Montgomery was an East Coast trawler

* * *

Now that radio brings its annual deluge of Christmas greetings from all parts of the world, the basic similarity of this great festival in different lands cannot pass unnoticed Certainly, in America, celebrations have a very English flavour You have the same feverish preparations, parties, carols, and traditional turkey This year proved exceptional in only one respect, for the sun shone brilliantly in a still blue sky Against this summer background, it was difficult to accustom oneself to heavily decked Christmas trees But at night, when the soft glow of coloured candles brought warmth and friendliness to hundreds of windows in every street, and the strains of *Good King Wenceslas* could be heard in the distance, the weather no longer seemed to matter

* * *

When, a few days before Christmas, a parcel labelled "football" arrived for Jonathan (aged 10½), I thought it prudent to inspect the contents before passing them on to Santa Claus for delivery My prudence was justified, for the parcel contained an obviously very fine and expensive (association) football in a state of collapse After struggling with and breaking the frayed suture I managed to extract the bladder, in doing so I removed the skin from the backs of three of my fingers and a portion of what appeared to be a collar from the neck of the very special seamless bladder An exciting few minutes were then spent, fruitlessly, trying to inflate the bladder with my car foot-pump Next morning I took the football, bladder and all, to a well-known sports shop in the West End, and asked the muscular young assistant to put it into working order He looked at me with scorn "We don't blow footballs up here, sir," he said "Not even on Christmas Eve?" I asked "No, and you won't get very far with that bladder" Besides a part of the collar, I had removed a section of the bladder wall

When I had bought a new bladder, an adaptor for filling the bladder from a pump, a new suture looking like a bitterminally amputated bootlace, and a large blunt needle for lacing up the latter, I had spent enough for quite a handsome present for Jonathan, but I felt well equipped to cope with the situation Arriving at hospital, I met a younger colleague who a year or so ago had been one of the stalwarts of the United Hospitals soccer team Just the man for the job, I thought, and handed *him the football and my purchases It took him an hour* and a half, with the aid of the laboratory motor pump, to assemble the football ready for use

At 2 a m on Christmas morning I was awakened by a musical tinkling A late carollers' percussion band? No, just the football sailing out of the children's bedroom window

* * *

I rang up the clinic and asked for an urgent appointment for that afternoon The first thing the secretary wanted to know was the patient's name, I countered by saying that I first of all wanted to know if it would be possible for her to be seen that day, *regardless of what her name might be* To this the secretary replied that it all depended on whether or not her surname began with any letter between A and K as they had a new system I could not help but reflect on the marvels of modern medicine when the urgency of a complaint could be influenced by the chance of one's initials

* * *

Quid pro quo is the basis of our relationship with Joe He is our plumber and I look after his dad

The trouble with our house is that four generations of doctors have lived in it The earlier three were either pioneers of the do-it-yourself movement or victims of evolutionary skill in Joe's forebears The trouble with Joe's dad is that corrosion and hard waters have played hell with his own piping systems, which are also of the 1875 vintage Our intercepting trap in the front garden vies with the old boy's prostate for retention symptoms His long-standing hyperpiesia contrasts with the chronic low pressure in our lavatory cistern Joe and I often shake our heads over the imperfection of each other's professional responsibilities Mind you, we do deliver the goods from time to time Ten minutes' work with a set of drain rods or a Higginson syringe can provide thankful relief for both of us Joe's skilful version of an unwanted teddy bear to bring down a leg round the bend made him all square for a similar little job I did for their Elsie It does not pay us to be too critical of the ins and outs of each other's households

Most of our common problems have been physiological, and restoration of function has been our guiding principle—removal of physical obstruction, speeding the circulation, adjusting the pressure on valves and cisterns, soothing the intima, relieving the air-locks and gases, heat-exchange systems, and temperature regulators But physiology cannot take us all the way, and this week anatomy reared its ugly head

Our kitchen range packed up, and my better half wants one of those newfangled stoves put in the opposite corner of the room We handed the place over to Joe, and went to cook snacks over a bunsen in the dispensary Someone was fairly letting fly in the back regions, and then there came a knock on the surgery door Joe requested a domiciliary consultation in the kitchen, so down I went The extent of the laparotomy was more worthy of a necropsy than an operation with a hopeful prognosis The scene was vaguely familiar pipes everywhere, swabs and buckets, overalls and puddles, even to the tea on the trolley Joe was worried about that there big pipe in the middle it did not seem to go nowhere, and maybe only his great-grandad knew where it came from but it was certainly too much in the way in 1957 I suggested radical excision Joe looked horrified, for empiricism was not his line Impatiently I snatched a pickaxe from the floor and buried its point into the lumen of the mystery aorta A trickle of rusty fluid seeped out, but nothing more untoward happened I commanded Joe to cut the section out and hammer up the patent foramina in the wall We have known each other too long for him to disobey, but he gave me a nasty quizzical look If our village gets snowbound again this winter, I doubt if Joe will let me pick up a scalpel to his dad He distrusts my modus operandi

Letters to the Editor

COLITIS FROM GANGLION-BLOCKING DRUGS

SIR,—Kitchin et al [1] refer to diarrhœa as a troublesome complication of treatment of hypertensive patients with mecamylamine This side-effect needs to be stressed because the ganglion-blocking drugs are generally believed to produce constipation, and hence may be overlooked as the cause of diarrhœa Their continued administration may have disastrous results

In the past few years we have encountered three cases of severe diarrhœa and shock in patients treated for a long time with oral pentolinium

The first patient died after operation and at necropsy was found to have a large sloughing ulcer of his cæcum and ascending colon A second patient was found at operation to have a gangrenous cæcitis, which was treated by cæcostomy She recovered after a stormy illness A third patient developed similar features, but began to improve with the prompt cessation of the ganglion-blocking drug and the administration of intravenous fluid and electrolytes Her symptoms recurred after she was given, inadvertently, another dose of the drug She eventually recovered

This severe bowel disturbance was tentatively attributed at first to a high concentration of the ganglion-blocking drug in the bowel, and therefore seemed less likely with a drug which was rapidly and completely absorbed in the upper part of the small bowel, as was presumed to occur with mecamylamine However, there are indications that mecamylamine may also cause colitis

We have recently encountered in a patient under treatment with mecamylamine severe diarrhœa and shock leading to anuria and death At necropsy there was widespread ulceration of the large bowel Another patient taking mecamylamine developed severe diarrhœa which became so bad as to amount to fæcal incontinence This stopped two days after she ceased taking mecamylamine

The ganglion-blocking drugs have now proved their worth in the treatment of severe hypertension, but it is prudent to remember also the dangers of their use and to take these into account, particularly before embarking on treatment of patients with the milder forms of hypertension

SANATORIA BEDS

SIR,—A year has passed since my plea [2] for the preservation of the small sanatoria was published in your correspondence columns

This year has seen a further drop in the number of patients requiring or willing to accept sanatorium treatment for tuberculosis Nowadays admission to sanatorium is rarely indicated A spell of a few weeks following diagnosis to teach the patient how to take the drugs, and see they are tolerated, is useful, particularly with the less intelligent patients Seriously ill patients with tuberculosis are not often seen, but would have to be admitted, as would the homeless, the vagrants, and those who prove too difficult to manage at home

Undoubtedly all these groups of patients are much better handled in small sanatoria than in the large institutions, which tend to have strict rules and regulations that prove irksome to patients who, in the vast majority of cases, feel well Should the rules and regulations be broken the patient may be discharged and refused admission in the future Furthermore, the traditional " dos and donts " taught in these institutions, which have little scientific basis, tend to induce a state of hypochondriasis in certain patients

Surely efforts should now be made to close the large sanatoria which are showing an increasing number of empty beds, but which interested parties and ill-informed administrators strive to maintain Sentiment should be disregarded in this matter, as many of these larger units could be readily adapted as general hospitals or geriatric units, for which the need is so much greater

The more homely atmosphere and less stringent regulations of small units would more than compensate for the possibly slightly increased cost per bed and, furthermore, would prove easier to adapt to the changing needs of tuberculosis

Bournemouth O D BERESFORD

CHEST X-RAY EXAMINATIONS AND RADIATION HAZARDS

SIR,—I have read with interest the article by Dr J B Clark and Dr R Grenville-Mathers (Dec 21) But is it not " straining at a gnat and swallowing a camel " to concern ourselves unduly with the use of chest X-rays for diagnostic purposes in chest clinics whilst patients undergoing treatment by an artificial pneumothorax or, worse, an artificial pneumoperitoneum are subjected weekly for a period of years to fluoroscopic examination involving a dose of radiation greater than that received during almost all diagnostic chest X-rays (excepting, of course, tomography)? All the greater is the alarm when one recalls hearing the advice given casually " Give him a P P " rather than do nothing

Hastings A W ANDERSON

RESPONSE OF MEGALOBLASTIC ANÆMIA TO PREDNISOLONE

SIR,—The article of Dr Doig and his colleagues [1] on the effect of prednisolone in megaloblastic anæmia was of interest, since I have investigated the effect of adrenal corticosteroids on the absorption of vitamin B_{12} in several patients with pernicious anæmia It seemed worth while to evaluate the action of the corticosteroids, since a beneficial effect could explain the spontaneous remissions of pernicious anæmia that have been described [2]

One patient with pernicious anæmia in relapse received 40 mg of prednisone daily for 2 weeks There was no hæmatological response, the bone-marrow remained megaloblastic, and the serum-vitamin-B_{12} level of 0 $\mu\mu$g per ml remained unchanged The fæcal excretion of radioactive ^{60}Co B_{12} in this patient was 98% before prednisone and 86% while receiving prednisone In three additional patients with pernicious anæmia in remission, the fæcal excretion of ^{60}Co B_{12}, compared with control studies, was decreased by 9–12% while receiving corticosteroids

There are several mechanisms by which the corticosteroids might produce a remission of megaloblastic anæmia due to vitamin-B_{12} deficiency—by a direct effect on the bone-marrow, by increasing the secretion of intrinsic factor, or by facilitating the absorption of B_{12} by a presumed non-specific effect on the intestinal mucosa as in the treatment of idiopathic sprue

The decrease in fæcal excretion of radioactive B_{12} found in the patients receiving steroids is small, but may be significant A slight increase in the absorption of vitamin B_{12} could result in the delayed hæmatological response observed by Doig et al Obviously, further studies are necessary to elucidate the action of corticosteroids in megaloblastic anæmia due to vitamin-B_{12} deficiency

INTELLIGENCE OF DRIVERS

SIR,—On each of two recent journeys on the Great North Road I found a large motor-van coming towards me in my lane on a dual carriageway which, though recently opened, was properly marked The lack of perception on the part of their drivers calls to mind the number of drivers of goods, and even public-service, vehicles who failed to reach the standard on psychological tests required by the Army during the late war

Mental subnormality in a driver is a more serious matter than is generally realised At present a mental defective under any form of statutory care is debarred from holding a driving licence—provided he writes "no" in the proper place on a form which has already provided the basis for a satirical sketch on B B C television and is probably as clear to him as an income-tax form is to some of the rest of us Once discharged from statutory care this same defective can apply for his driving licence, and, unless the licensing authority has been informed of the circumstances, get it

It is to be hoped this subject will receive proper attention in the legislation which is to follow the report of the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency But what of those still dangerously lacking in mental ability who escape the notice of the authorities ?

PEPSINOGEN IN URINE AND BLOOD

SIR,—Your annotation (Oct 19) touches many aspects of this fascinating subject and invites comment As one who, you suggest, put forth the claim that uropepsinogen excretion quantitatively reflects gastric pepsin output, may I make a comment ?

The entrance of pepsinogen both into the lumen of the stomach and into the blood, whence it finds its way into the urine, represents only one example of what Dr Hollander and I[1] have elsewhere called the exocrine-endocrine partition of digestive enzymes The evidence regarding this partition ratio was of a statistical nature, but, more important, the evidence was obtained under clearly defined basal conditions This latter point is often overlooked in the by now voluminous literature on the subject

The studies by Hirschowitz et al to which you refer are valuable for exploring the effects of corticotrophin and cortical steroids on this exocrine-endocrine partition Recent work by Rider and colleagues[2] indicates that irradiation of the stomach may alter this partition, and Spiro et al[3] have emphasised the effects on it of inflammatory lesions of the stomach

All these investigations have enlarged the number of variables which must be taken into account, but do not necessitate "complete revision of ideas on the relation of these levels to gastric pepsin output" They cannot invalidate the many articles, some cited in your annotation, which document the clinical usefulness of this measurement

Mount Sinai Hospital,
New York.

HENRY D JANOWITZ

THE REINFORCEMENT OF TENDON-REFLEXES

SIR,—To reinforce, say, an ankle-jerk, ask the patient to hook the fingers of his two hands into each other and tell him that you are about to ask him to pull one hand hard against the other Then say "Are you ready ?" Then, without giving the expected command, strike the Achilles tendon, and you will obtain as much reinforcement as if you had given the command

That is what I was taught years ago, and I have proved the truth of it many times, or at least I think I have Perhaps, relying on clinical impressions, I have deceived myself In the excellent paper by Dr Buller and Dr Dornhorst (Dec 21), it would have been valuable to have fig 3 supplemented by tracings to show the reflex 0 2 or 0 3 seconds after the mere inquiry "Are you ready ?" If reinforcement were demonstrated, it would not invalidate these authors' view of the role of the small motor nerves, but it would, I think, invalidate their statement that there has to be a movement involving effort

London, W 1

JOHN PENMAN

B P AND PROPRIETARY PREPARATIONS

SIR,—*The time is ripe for reassessment of the policy of* the Ministry of Health and Treasury in regard to proprietary medicines The report of the Cohen Committee (which is the basis of official policy) concedes that the pharmaceutical industry has contributed a (comparatively) small *number of outstanding drugs not yet in the B P* Apart from these, everything *B P* is "good enough", and there is no need for manufacturers to introduce "slight variants" (to quote a recent critic) of official remedies

Such an attitude is contrary to the whole course of scientific and industrial advance Progress does not consist only in a few outstanding discoveries, but also in the cumulative effect of a host of small advances and improvements As I have pointed out elsewhere, the motorcar of today does not differ fundamentally from its predecessor of fifty years ago 4-stroke engine, carburettor, clutch, gear-box, transmission, differential, &c But in performance and comfort it has been transformed by constant modification and improvement in detail Similarly in pharmacy Progressive manufacturers are continually seeking to produce "something better" than *B P* They spend large sums, not only on *fundamental research to discover* new drugs, but on formulation research and process research to find better ways of making, using, and combining existing drugs *Modern* drugs are extremely complex and often yield their maximum efficacy only under carefully controlled conditions A wide range of new excipients have been introduced, affording immense scope for experiment and modification The effect of a medicine is not measured by the percentage of the active ingredient The choice of excipient, the physical state of the ingredients, and other factors may materially enhance the drug's therapeutic efficacy To give only one illustration there are no less than three hundred different emulsifying agents at the disposal of the manufacturer from which to select the one best suited to a particular purpose

The Pharmacopœia Commission have not the staff or resources *to do much research* Advances *come* almost invariably from the industry's research laboratories, and may *be reflected in B P standards and* formulations some years later

The existence of standards, whether *B P* or B S I, is a challenge to a manufacturer to go one better, and it would be a bad thing for medicine, for the N H S, and for the export trade if this were not so

It is really time that the *Ministry* and its fellow critics ceased to represent the *B P* as "best possible", and took to heart *the conclusion in Mr J P Martin's* recent book

Social Aspects of Prescribing that, in selecting proprietary medicines as the principal cause of the high cost of the pharmaceutical service, they are barking up the wrong tree

In a world which is becoming increasingly proprietary-minded the constant denigration by the Ministry of British proprietary medicines may react to the detriment of British exports

Horsham, Sussex. F F MARCHBANK

LEAD POISONING

SIR,—Dr Gillet in his letter of Dec 14, referring to my article of Nov 30, has asked for evidence of the route of entry of the lead

No direct evidence was obtained Ample opportunity for ingestion and inhalation existed Because inhalation is generally regarded as more toxic, this route was considered the more important

Some confirmation of this seems indicated by the fact that the husband and two elder boys who spent little time in the shack presented no evidence of lead absorption, but the wife and younger children who spent more time in the shack did

As far as contamination of food goes, all members of the family would have been at somewhat equal risk

CONTROL OF ARTIFICIAL RESPIRATION IN POLIOMYELITIS

SIR,—Dr Walley's paper of Dec 7 raises a number of interesting points in the application of intermittent positive-pressure respiration (I P P.R.) One which has had little attention to date is the interaction, under these conditions, of respiratory factors with metabolic processes in the acid-base balance of the body

Case 1 of Dr Walley's series was clearly in a state of respiratory acidosis due to pulmonary atelectasis This was corrected But the figures cited for blood pH, carbon-dioxide tension, and total carbon dioxide show that the patient then passed, perhaps insidiously, into severe metabolic acidosis Death was stated to have been from anuria

Metabolic acidosis associated with renal failure is by no means an uncommon cause of death among patients undergoing I P P R The factors contributing to it have yet to be fully understood The acidosis may result not only from abnormal metabolic events, such as ketosis in the initial stages of the illness, but also from impairment of the renal mechanisms which sustain the normal pH of the blood.

In conditions which require long-continued artificial respiration an extra burden is imposed on renal function in two ways Firstly, the inevitably increased catabolism of tissue protein requires the excretion of an excess of nitrogenous degradation products This osmotic load may be further reinforced by injudicious feeding with high-protein mixtures Secondly, fixation of the ventilatory volume to a predetermined empirical figure eliminates the partial respiratory compensation which normally follows a metabolic disturbance of the plasma-bicarbonate level [1] Hence there must be increased strain on the renal pH-regulatory mechanisms

The elasticity of renal function may be further reduced by anoxæmia, by toxæmia, and possibly also by changes in the visceral venous blood-flow due to hæmodynamic "back pressure" from the positive endobronchial pressure used for respiration There is some evidence that hepatic function may be modified by this back pressure [2] A high inflating pressure or a shortened expiratory pause, either of which may be needed to maintain an increased respiratory minute volume, results in a raised mean intrathoracic pressure

Disturbances of electrolyte balance can occur in a variety of conditions which may necessitate artificial respiration Suppression of urinary excretion of the sodium and chlorine ions has been described in bulbar poliomyelitis and other intracranial lesions,[3] and of the chlorine ion in tetanus [4] If present, these disturbances add to the complexity of the metabolic picture

Dr Walley has rightly emphasised the importance of blood-gas analysis in the control of long-continued artificial respiration, and in so doing has pointed to other problems

PRODUCTION OF FIBRINOLYTIC ACTIVITY WITHIN ARTERIES

SIR,—May we reply briefly to Prof McFadzean's letter of Dec 21?

Firstly, we apologise if our reference to his and his colleagues' work was misleading

Secondly, Professor McFadzean believes that local anæsthesia increases fibrinolytic activity in the vessel from which blood is obtained. In our investigation a local anæsthetic, lignocaine, was used for the arterial punctures, no anæsthetic being used for venepuncture Since we found arterial-blood fibrinolytic activity to be less than venous-blood fibrinolytic activity, we do not see that the second part of Professor McFadzean's letter is relevant to our findings

Finally, we have tested venous-blood fibrinolytic activity with and without lignocaine anæsthesia, and find no difference.

RADIATION AND LEUKÆMIA

SIR,—The report [5] by Court Brown and Doll on "leukæmia and aplastic anæmia in patients irradiated for ankylosing spondylitis" is outstandingly valuable for the estimate that it gives of the increasing incidence of leukæmia with increasing radiation dose in these patients It has in addition, however, been regarded as indicating the probable absence of a threshold for the induction of leukæmia by radiation, despite the authors' warnings that their information on this point was inadequate to justify a definite conclusion

In view of the importance of this subject it would be valuable to have the authors' estimate of their evidence on this question It is obvious that the regression line used in the report is inappropriate to a study of possible thresholds since it is "calculated from the rates for the (various) dosage groups and made to go through the point corresponding to the incidence in the absence of treatment." It would, however, be valuable to know the line of best fit to the points for the irradiated patients only, and so to obtain an estimate for the dosage at which the incidence of leukæmia is no greater than in unirradiated subjects It is clear that such an estimate of a "threshold" may be highly inexact and the confidence limits of the estimate would be helpful in demonstrating this It is clear also that no reliable deduction can be made by the extrapolation of a regression line in this way The need, however, is to assess what inferences as to the likely size or existence of a threshold are indicated, and what are probably excluded, by the observations on which the report is based

NITROUS-OXIDE BYPASS ON ANÆSTHETIC APPARATUS

SIR,—There are still numbers of anæsthetic machines in use which have a bypass providing a rapid flow of nitrous oxide as well as one for emergency oxygen The two controls are alike, though at opposite ends of the row of flow-meters It can easily happen in the stress of an emergency that the wrong bypass is opened when it is intended to inflate a patient's lungs with oxygen At least one fatality has been caused in this way I suggest that lives may be saved if every anæsthetist who uses a machine that has a nitrous-oxide bypass takes steps to have it removed

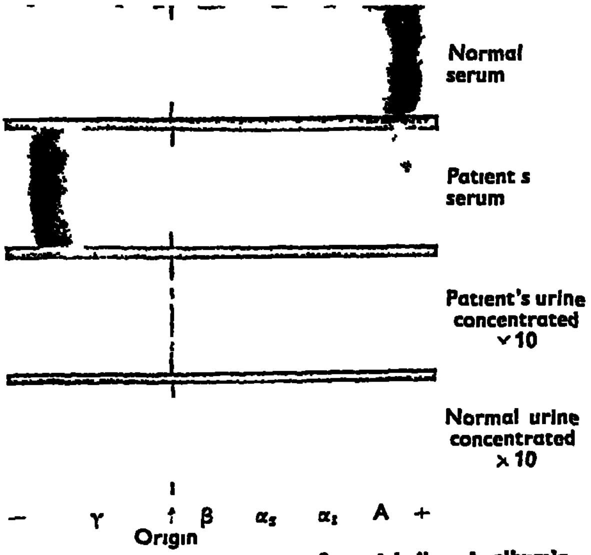
UNUSUAL URINE PROTEIN IN *MYELOMATOSIS*

SIR,—Mr Cummings,[1] in describing the urinary-protein electrophoretogram from a case of myelomatosis in which there were three bands in the γ-globulin region, reported that this was the only instance in some 40 cases in which he had found more than one band in this region In Dr Gobert-Jones' case[2] two bands were present in the γ-globulin region

We have recently investigated a patient in whose urine there are apparently four distinct proteins The electrophoretic pattern shows two distinct bands in the region corresponding to the γ-globulins, a fainter one in the region corresponding to the β-globulins, and a fourth which is albumin (see fig)



Normal serum

+
Origin

Electrophoretograms —α_1, α_2, β, γ-globulins, A, albumin

A man, aged 47, presented with aching limbs and symptoms of anæmia In addition to the urine and serum findings, smears of a marrow aspirate and radiographs were typical of multiple myelomatosis The urines were concentrated ten times by freeze-drying and resolution in *0 05 M* barbitone buffer (pH 8 6) Both the urines (0 05 ml) and sera (0 01 ml) were electrophoresed on Whatman 3 mm paper in a horizontal bath using 0 05 *M* barbitone buffer (pH 8 6) for thirteen hours at a current of 1 2 milliamps per strip

We are at present studying the relative value of different urine tests in differentiating myelomatosis proteinuria from that found in other conditions As an aid to our study we would welcome specimens of urine containing protein from cases of proved or suspected myelomatosis

TROPICAL EOSINOPHILIA

SIR,—In their preliminary communication of Sept 7, Dr Gault and Dr Webb reported what appears to be the anterior end of a nematode larva in the liver in a case of tropical eosinophilia, they have also shown gross pathological changes in the liver

It is increasingly being realised that, in tropical eosinophilia, tissues other than the lung are commonly affected Chaudhury,[1] in his series of 167 cases of tropical eosinophilia noted enlargement of the liver in 52 cases, symptoms other than pulmonary (mainly gastrointestinal) in 42, splenomegaly in 14, and enlargement of lymph-nodes in 5 Gupta and Rao[2] have reported eosinophilic nodule of the breast in a case of tropical eosinophilia

The work of Danaraj et al[3] with a filarial complement fixation test, and that of Gault and Webb, strongly support the view that parasitic infection plays an important part in tropical eosinophilia, and that most of these cases are probably of filarial origin Filariasis exhibits itself in a wide variety of diverse and apparently unrelated clinical conditions Apart from the well-recognised clinical features, various other manifestations, such as mastitis, parotitis, thrombophlebitis, rectal bleeding, pruritus, erythematous or papular eruption, have been thought to be due to filarial infection[4] Janssens[5] noted various nervous and psychic manifestations of filariasis This variety of clinical conditions may be explained on the basis of lymphatic blockage and vascular allergy

It seems, therefore, that tropical eosinophilia is just one of the many manifestations of filariasis In spite of the fact that filariasis is so widely prevalent, our knowledge of the disease is woefully deficient

B S RAHEJA

A FUNCTIONAL NECESSITY

SIR,—Once again *The Lancet* has advocated the permanent creation of a new grade of hospital doctor intermediate between senior registrar and consultant The letters of Mr Holmes Sellors, Dr Rowland Hill, and Professor Strachan must have made it clear that the representatives and leaders of the consultants are opposed to such a plan I should like you to know that the same is true for the senior registrars and registrars The B M A Hospital Junior Staffs Group (formerly Registrars Group) provides representative machinery to which all members of these grades have access, and the problem of hospital staffing has been our chief concern for the past four and a half years Everywhere and always, the majority opinion has been against a permanent subconsultant grade Of course, there are some now in urgent distress, men around 40 in the major specialties, with higher qualifications, long specialist experience, and satisfactory records who are threatened with dismissal Plans for a subconsultant grade may tempt some of them as a straw tempts a drowning man If a few should even clutch at it, that would not be an argument for providing straws instead of proper lifesaving gear Nor would the fact that straws are cheaper

---

[1] Chaudhury R N *J Indian med Ass* 1956 27 195

[2] Gupta I M Rao, M S N *Indian J med Sci* 1957 11 729

[3] Danaraj T J daSilva L S Schacher J F *Proc Alumni Ass Malaya* 1957 10 109

[4] Raheja B S [illegible] (in the press)

[5] *Ann S belge Méd trop* 1952 32, 229 See *J Indian med Ass* 1954 23 269

In considering plans for future hospital staffing much confusion arises unless it is recognised that there are two quite separate problems An immediate solution is needed to mitigate the hardships of the ageing time-expired senior registrar and this must be followed by a long-term solution which will ensure that similar hardships, or others as bad, do not occur again It is absolutely vital that the short-term plan should be consonant with the long-term one, and that the long-term one should be based on serious consideration of what is best for the hospital service, not dictated by the short-term plan To do otherwise is to sacrifice the future to the present.

You do not clearly define the grade of assistant consultant which you propose Evidently it is to be a permanent feature of the service, inferior in status and remuneration to the consultant grade and to offer a career up to retirement in all specialties Immediately, one wonders what work there could be in hospital, suitable for a man over 40 with higher qualifications and long specialist experience which is not consultant work. Dr Rowland Hill says none at all The examples you suggest (presumably the best you could think of) should convince all that he is right

It is widely known that much work which should be carried out by consultants is at present done by senior registrars and even registrars Is it possible to believe that the work allotted to the proposed new grade would be anything less or that the men in the grade would be suitably occupied if it were? It could only be a grade of underpaid, dissatisfied, depressed consultants The financial convenience to the Government of such a grade is obvious Once introduced, nothing could withstand continual pressure from the Treasury to increase the proportion of subconsultants

What then are the correct solutions? As always, close examination of the problem suggests the answer At present, there are too many *senior registrars in the major* specialties in relation to the incidence of consultant vacancies (over 200 each in medicine and surgery compared with an average of 20–30 consultant retirements annually) On the other hand, many senior registrars and registrars are doing work which ought to be done by consultants The correct long-term solution is to create new consultant sessions to cover this work, and discontinue some of the senior registrars' posts thus vacated By these two processes, a proper ratio between the senior registrars and consultants could be established which would allow reasonable prospects of advancement after four years as senior registrar It would also relieve the bottleneck between registrar and senior registrar, and make possible the attainment of a consultant post around 32 years, as envisaged by the Spens Committee

Such an agreement could not be implemented overnight (though there is nothing to prevent the Ministry of Health accepting it in principle forthwith) In the meantime, the present generation of time-expired senior registrars are existing insecurely from year to year on an arrested salary, growing ever older and accepting ever more independent responsibility Their needs as well as their contribution should be recognised by the granting forthwith of security of tenure and a rising incremental scale to those retained after four years This would lift their burden of insecurity, and substantially relieve their financial hardship Yet it in no way interferes with the final solution, or even commits either side as to its nature

ROGER BREARLEY,
Chairman
Liverpool B M.A Hospital Junior Staffs Group

SIR,—The interest taken in your leading article of Nov 30 is further evidence of the urgent need for a satisfactory solution of the problem of hospital medical staffing The S H M O Group of the B M A is profoundly dissatisfied with the present position but is very suspicious of any attempt to create an alternative grade in view of the following grave errors and inherent injustices of the present position

(1) The initial formation of a vague "subconsultant" grade

(2) The expansion which has occurred in spite of the superficially fair document RHB 50/96

(3) The small effect and unbalanced reviews of gradings

(4) The Ministry's continued refusal to allow further reviews

(5) Decreasing possibility of obtaining consultant status

(6) Insidious threat of "clinical supervision" of fully trained staff

For a new grade to be acceptable to S H M O s there would have to be adequate safeguards to prevent a repetition of such past mistakes

All your correspondents have stressed the urgent need for an increase in the consultant establishment, and indeed if the needs of the country in this respect were adequately met the greater part of the problems of the senior registrars and S H M O s might well be solved

The present plight of the senior registrars is desperate and that of the S H M O s is little if any better This state is primarily due to the large amount of consultant work which is being done by these two grades Unofficially this is both well known and is an accepted fact, the time is long overdue for official recognition and action

Certain obstacles have to be overcome to provide a satisfactory solution It is my personal view that ways to do this have evolved from the work of various committees and the efforts of many earnest people The difficulties are as follows

(1) No sudden increase should be made on the country's financial burden

(2) Early selection for permanent consultant status

(3) Adequate and satisfactory opportunities for those who for one reason or another are not so selected

The first step should be to stop creating new senior registrars until the existing ones and S H M O s have been virtually absorbed by the formation of one consultant grade commencing at a salary scale lower than the present consultant minimum (relative), thus avoiding the financial strain of the necessary increase in the present consultant establishment

The salary scale should rise by regular increments to a predetermined level, such as not less than 80% of the present consultant maximum (relative) Attainment of the highest level would depend on responsibility and individual worth Such a solution would affect the present merit-award system in that ability and outstanding merit could be rewarded at all levels for permanent staff

"Supervision" is the cause of much uncertainty and concern, especially as it has never been accurately defined. Fully trained staff on a permanent contract should only be appointed where theoretical knowledge is sound and sufficient experience has been obtained to realise when to take counsel with a senior colleague The administrative division of duties by the senior consultant in a specialty is reasonable and would apply to all specialists in his area, but this would not be supervision of actual clinical work

There should be worth-while alternatives for those registrars for whom there are no available openings when they have finished their trainee period A loss of so much specialist skill would be personally bad and economically unsound

Reorganisation of the public-health and school services could provide a number of attractive posts if liaison with hospital work was developed, and group general practice, as has been so frequently suggested, should be enriched by recruiting from the registrar pool

The present hierarchy who control negotiations on the future of hospital staffing all come from the top end of the consultant ladder and are therefore not acutely aware of the economic difficulties of their juniors Adequate representation of all levels of hospital staff is therefore of paramount importance to obtain a satisfactory solution

Leicester G WARING ROBINSON

UNNECESSARY IRRADIATION IN CHEST RADIOGRAPHY

Mr H FISHER, technical manager of Sierex Ltd, writes

"The article by Mr Clarke[1] refers only to cones for limiting the radiography field No mention is made of the numerous adjustable diaphragms which are on the market, particularly those fitted with a light device for projecting the X-ray field on to the patient Our adjustable light diaphragm, which has come into widespread use in the past years, contains four sets of lead plates which are arranged so as to give optimum cut-off of the X-ray beam The use of such a diaphragm, which also has an accurate light centring device, obviates the need for special precautions—e g, protective screens—for the patient in order to shield the gonads or other vulnerable parts

The cut-off which we can obtain with our diaphragm is equivalent to the cut-off obtained with a lead-rubber sheet as used during normal radiography with a divided cassette, so that the use of such a diaphragm would obviously give optimal radiographic results as well as affording maximum protection to both patient and operator"

Public Health

Statistical Review of England and Wales

IN part I of his Statistical Review for 1956,[2] the Registrar General records the detailed statistics of deaths from all causes and notifications of infectious diseases in that year, by age, sex, area of residence, and time of year

Deaths—The death-rate of 11 7 per 1000 living was the same as that in 1955 The death-rate in the age-group 0–4 was the lowest on record

Stillbirths and infant deaths—The stillbirth-rate remained steady at 23 per 1000 (the rate for every year but one since 1948) The infant-mortality rate fell from 25 per 1000 in the previous year to a new low level of 24 per 1000 The number of deaths from pink disease was 75 in 1947 and 1 in 1956

Cancer—The number of deaths from cancer was 92,710—an increase of 1370 compared with 1955 Deaths from lung cancer increased by 914, the total being 15,615 in men and 2571 in women There were 2315 deaths from leukæmia in 1956, 2224 in 1955, and 1419 in 1946 18% of all deaths were due to cancer

Infectious diseases—There were 5375 deaths from tuberculosis (6492 in 1955), 8 from diphtheria, 15 from scarlet fever, and 30 from measles—all low records There were 114 deaths from acute poliomyelitis

Cardiovascular disease—Arteriosclerotic heart-disease caused 74,790 deaths in 1956, 70,597 in 1955, and 32,487 in 1946 Over 14% of deaths were due to this condition 20,398 deaths were attributed to hypertensive disease, compared with 20,920 in 1955 and 16,757 in 1949

Bronchitis—19,852 men died from bronchitis, the highest figure since the war, except for 1951, the figure for women was 9818

Violence—21,870 (21,460) persons died by violence—5915 (5743) in home accidents, 5236 (5170) in road accidents, and 5282 (5000) by suicide (figures for 1955 in parentheses)

Obituary

THOMAS PEEL DUNHILL

G C V O, C M G, M D Melb, Hon F R C S, F.R.A C S

Sir Thomas Dunhill, consulting surgeon to St Bartholomew's Hospital and sergeant surgeon to King George VI, died on Dec 22 at the age of 81 He was one of the group of distinguished medical immigrants from the Commonwealth who came to practise in this country after service in the first world war His special contribution was to thyroid surgery, and even when the memory of his own technique and dexterity has faded his influence in fostering the study and investigation of the endocrine glands will persist

Dunhill graduated M B with first-class honours from the University of Melbourne in 1904 and was already surgeon to St Vincent's Hospital in Melbourne when war broke out in 1914 He served in France with the Royal Australian Army Medical Corps and before the end of the war he was appointed consulting surgeon to the British Expeditionary Force For these services he was appointed C M G in 1919 His war-time contacts with his British colleagues led to an invitation to join the surgical unit at St Bartholomew's Hospital Soon afterwards he was appointed a full surgeon to the hospital

His first official appointment to the Royal Family was made in 1933 when he was appointed surgeon-in-ordinary to King George V, and in 1939 he became one of the sergeant surgeons to King George VI He was head of the surgeons attached to the Royal Household at the time of the King's illnesses in 1949 and 1951 Dunhill was appointed C V O in 1919, and promoted K C V O in 1933 and G C V O in 1949

Within his own profession and specialty his work was recognised by his appointment to the Arris and Gale lectureship of the Royal College of Surgeons of England in 1931 and again in 1934, and to the Lettsomian lectureship of the Medical Society of London in 1937, and by the award of the society's Fothergill medal in 1941, and the Cecil Joll prize in 1948 He received an honorary M D from the University of Adelaide in 1935, and he was elected to the fellowship of the Australasian college of surgeons the same year and to the honorary fellowship of the English college in 1939 Of the work which had earned these honours J P R writes

Thomas Dunhill's name will live in history because he made outstanding contributions to the surgery of toxic goitre, but those of us who knew him well must recognise that this statement, though true, is but *half*, or even *less than half* the truth

First, it is only part of the truth about the surgery of toxic goitre, for we cannot help thinking of thyroidectomy as it is performed today with all the safeguards provided by pre-operative medication and modern anæsthesia, and there is nothing in the statement to show that Dunhill shortly after becoming qualified realised that, contrary to current teaching, the *illest* patients were the ones who stood most in need of operation, and that he alone had the courage to tackle single-handed and successfully the problem of how to operate on these patients without killing them

---

[1] Clarke, W G *Lancet*, 1957, ii, 316

[2] Registrar General's Statistical Review of England and Wales, 1956 Part I Tables, Medical H.M Stationery Office, 1957 Pp 373 15*s*

Nowadays we are familiar with the idea that safety in surgery is a matter of team work, but Dunhill's team consisted of only two people, the patient and himself Recognising the dangers of contemporary anæsthetics he eliminated them by using local anæsthesia For the rest he trusted to gentleness, to knowing when to stop and completing the operation in stages, and to establishing in his patients such confidence that they were prepared to plunge into the deep waters hand-in-hand with him, knowing that he would do his utmost literally to pull them through This amazing story has unfortunately never been told, for Sir Thomas was too sensitive to publish it in his Joll lecture, and it is unlikely that it will ever be told now because Sister Mary Alban of St Vincent's Hospital in Melbourne who helped him with his early operations is an old lady and may not be able to commit her memories to paper It would take too long to go into details, but suffice it to say that Dunhill's pioneer work started in 1906, that he had established his reputation in this branch of surgery long before preoperative iodine became routine in 1923, and that he has been intimately associated with all the advances in the management of toxic goitre since that time

Secondly, the statement is only part of the truth because by concentrating attention on his work on toxic goitre it tempts us to forget his painstaking studies of other aspects of thyroid disease, especially of carcinoma of the thyroid gland, and it is also unjust to him in failing to mention the excellence of his technique in other fields of surgery

He was in the fullest sense of the term a general surgeon, at one time an able gynæcologist, interested and skilled in the treatment of fractures, familiar with the techniques of neurosurgery, and a brilliant exponent of operations such as radical mastectomy and block-dissection of the neck which demanded detailed anatomical knowledge Latterly he confined himself to the surgery of the abdomen and the neck, and made important contributions to the literature on diaphragmatic hernia and pharyngeal diverticulum

Dunhill was always anxious to learn by watching other masters of the craft at work Returning home he would incorporate into his own system anything which he regarded as a technical improvement, and provided that the modification stood up to his critical appraisal, he would accept it as his standard procedure He learned by example, and he taught by example Formal lecturing he dreaded, and his publications, though models of clarity, cost him a stupendous amount of labour Having given so much thought and attention to matters of detail, and having convinced himself that a certain method was the correct one, he was sometimes severe in his criticism of those who through thoughtlessness or ignorance did otherwise, and thus offended against some fundamental principle of surgery To attempt to live up to his high standards has been a stimulus to many a young surgeon, and the generation trained by him will realise that their efforts to perpetuate what they learned from him must be the most worthy tribute to his memory

F R F, describing Dunhill as " a man and a friend ", writes

> He was a big man in many ways He was a skilful and eminent surgeon but that was incidental It was as a man that he was unique, for he developed and used his capacities to the limits of his mental and physical endowment, and gave himself unsparingly to help his fellow men to a happier and a more complete life—not men as a race or a community, but each man, woman, or child with whom he came in contact and especially each who appealed to him for help To all he was sympathetic, courteous, and gentle, with a kindly sense of humour
>
> His restless body with its quick movements seemed the natural partner for his mind—a mind ever hungry for new facts and new thoughts and ever probing for gaps in his own knowledge in order that he might try to fill them In this endeavour he was tireless, talking on the telephone or writing, if that were more convenient, to any expert who might help him to see more clearly the problem of his patient and how he might help There seemed to be no half measure for him when engaged on a problem, but he knew his physical limits and in later years while still busily engaged professionally, he would lie down for a few hours to gain strength for the next task This output of energy, which seemed beyond that of other men, was given not only to his professional work but also to his trout and his salmon fishing, to shooting, to his appreciation of craftsmanship and art, to hospitality, and above all to his friendships Nothing but the best was good enough for him, and he would arrange as efficiently for a day in the country as for a journey to Australia, for a dinner-party in his home as for a critical operation on a person of international importance Worldly success came to him but he only welcomed it in order that he might more readily help others
>
> His example had an educative value impossible to measure, for while his skill in the execution of delicate operations gave him eminence as a surgeon, his study of his patients as persons, of their apprehensions, their worries, and their joys, and his understanding of their disturbed physiological functions were characteristic of the best physicians His daily life was a lesson on how each can make the most of his talents in the service of mankind, and on how to see and seek the best in others

JOHN JOYCE KEEVIL

D S O, M.A, M.D Cantab, D T M. & H, F S.A.,
F.R.Hist.Soc., J.P

Commander Keevil, who died on Dec 16 at the age of 56, had found time in a comparatively short life to win distinction as a naval medical officer and as a medical historian In these last years he had drawn these two careers together, and the first two volumes of his medical history of the navy, the second only lately completed, will be a fitting memorial to a sailor and a scholar

He was educated at Marlborough, Gonville and Caius College, Cambridge, and St Thomas's Hospital Soon after qualifying in 1925 he joined the Malayan Medical Service, but in 1927 he joined the Royal Navy as a surgeon, where he rose to the rank of surgeon commander in 1937

At the beginning of the late war he was senior medical officer of H M S *Illustrious*, the aircraft carrier In January, 1941, the *Illustrious*, while helping to convoy troopships from Gibraltar to Greece, was attacked by a mixed Italian and German force of dive-bombers, high-level bombers, and torpedo-bombers She was hit by 7000 lb of bombs, and 125 officers and men were killed and a greater number injured During the battle, amid blast, flame, and death, Keevil and his two junior medical officers rescued the wounded, rendered first-aid, and performed operations in a dark and flooded theatre

Keevil's critical report on the medical aspect of the battle and his recommendations did much to help the Medical Department of the Admiralty in evolving the new medical organisation for action in H M Ships afloat. In particular, the site and construction of sickbays were reviewed For his services Keevil received the D S O

After a period of service on shore he was appointed the first naval editor of the *Official Medical History of the Second World War* Here his judgment and experience were employed in planning the scope of the naval volumes of the *History* and in collecting material for them Where possible, the framework which Keevil constructed has been followed in the two published volumes A S M writes

Keevil proved a delightful colleague on the editorial committee of the *Medical History* He could be outspoken and critical in his opinions, at times even cynical, but he gave excellent counsel and untiring assistance, and his comments were often spiced with wit He was of medium height, dark, and clean shaven His manner, while always courteous, was somewhat reserved, but this only masked a kind and generous disposition Though always ready to give of his wisdom to other students of medical history, he was modest and unassuming about his own attainments

Keevil resigned the naval editorship to serve at sea again in the concluding years of the war, and retired from the Navy in 1946

For the rest of his life Keevil was a medical historian While serving at sea he had kept up his scholarship, and in 1948 he was appointed the first post-war keeper of the library of the Royal College of Physicians

There he was faced with the literally burdensome task of handling and arranging thousands of books which had been in storage His rearrangement of the library, under the direction of the Harveian librarian, was admirable and he did much research into the *Annals* and manuscripts of the college This work was embodied in his readable biographies of the two Hameys—*Hamey The Stranger* (1952) and *The Stranger's Son* (1953)

His attainments were recognised by election to the Society of Antiquaries, and after he retired from the college he found congenial work as an inspector and adviser on private collections of manuscripts under the National Register of Archives But his chief task and interest was of course his history of the naval medical service, and many will share his colleague W R L 's regret that Keevil "has left his tale half told" Of this important project F H K G relates

When I became scientific secretary of the Wellcome Trust in 1955, the trustees, on Prof T R Elliott's recommendation, had already agreed to sponsor the preparation and publication of this work, and in my second year with the Trust I received from Keevil the typescript of volume I, covering the period 1200 to 1649 It was accompanied by a charming and modest letter in which he said that he would welcome any comments which I, as an experienced editor, would care to make upon it I saw at once that it was a work of rare scholarship, and I soon found that the only suggestions I could make about it related to *trivia* and to points about which a reader less well-informed than the author might be glad of further explanation All these suggestions were received by him with tolerance and gratitude (though many of the queries admittedly were born of my own ignorance), and we became firm friends

At the time when volume I was published last summer, Keevil had already had the first severe attack of his illness As soon as he was allowed to resume work he completed the writing of volume II, but in continuing the history he was handicapped by no longer being able to come up to London to work in the libraries, particularly that of the Royal Hospital at Greenwich, on which he depended so largely for source material for volume III I was therefore glad that I was able to introduce to him Dr Edwin Clarke, who could help him with the library research Thanks to the author's indomitable spirit, and the support and help of his wife—herself a writer of distinction—the typescript of volume II was sent to press a few weeks ago, and on the day that Keevil died I received from him an optimistic letter indicating that volume III was beginning to take shape That volume and the intended final volume must, it seems, be lost to us, but it is good to know that Keevil had the satisfaction of seeing uniformly enthusiastic press notices of his first volume, and that volume II, bringing the story of British naval medicine to the year 1714, will in due course appear as a further important contribution to British historical scholarship, and a lasting memorial to a remarkable man

Commander Keevil married in 1946 Averil Salmon, daughter of Robert Mackenzie-Grieve of Torrington, and she survives him

THOMAS RICHARD GODDARD

M R C S

Dr Goddard, who died on Dec 17, qualified from University College Hospital in 1925, and soon afterwards settled in practice at Hemel Hempstead He remained there until he retired a few years ago to Berkhamsted Of Dr Goddard's eventful and unorthodox apprenticeship to medicine his old chief P H M -B writes

When I was ordered up from Cairo in 1917 to organise a field laboratory in close contact with the large casualty-clearing station at Rafa behind the Gaza front, I found Sergeant Tom Goddard there as my main prop, and it was largely due to his knowledge of laboratory technique, skill, and efficiency that this vital laboratory service was in working order within 4 hours From that time onwards until we were demobilised in 1919, we worked together There was no lack of material, for we were really part and parcel of the adjoining hospital so that we were immersed in the diagnosis of dysentery, malaria, relapsing fever, typhoid, and many other disorders all day long and often far into the night Not infrequently we handled 50 specimens of faeces a day and sometimes even more

It was Goddard who helped to organise the malaria diagnosis stations without which Allenby might not have advanced to Aleppo in September, 1918, and on him I relied to help train our personnel in the intricacies of hæmatology and malaria diagnosis for this task. It was he who concocted the MacConkey's media upon which he cultivated the dysentery bacilli in those memorable days, and it was he who helped to isolate cholera vibrios on Dieudonné's medium, when an epidemic threatened the Army at a critical time early in 1918 and which was scotched by the detection and elimination of carriers "inside three weeks"

Goddard, too, was always interested in our private zoo, where we had cages containing desert rats, gerbils, and jerboas which wandered into our tent at night, and little owls, quail, corncrakes, larks, and various warblers which flew in in the daytime Sometimes he was called upon to deal with camel convoys which arrived at the modest E P I P tent, which served as our main laboratory, laden with stools from suspects as far away as Beersheba

In the rough-and-tumble of war pathology Goddard could always be relied on to be loyal, competent, and efficient, and the experience he gained served him in good stead when he decided to take up medicine directly after demobilisation So keen and studious was he that he soon completed his medical course and settled down as a most capable and successful family doctor

ARTHUR JAMES EWINS

D Sc Lond , F R S

Dr A J Ewins, director of research to May & Baker Ltd , who died on Dec 24 at the age of 75, was associated with the late Sir Lionel Whitby in the joint investigation which led to the introduction of sulphapyridine Though this drug has now been largely superseded by newer remedies, its workaday laboratory name (M & B 693) caught the public imagination and "M & B" is still widely, if inaccurately, used for any sulpha derivative

Ewins was the son of a railwayman in South London He won a scholarship to Alleyn's School, Dulwich, and later worked as a technician at the Wellcome Laboratories, then at Herne Hill With the help of evening classes he took his B SC Lond in 1906 and joined the scientific staff of the laboratory In 1914 he took the D SC , and the same year he moved, with his chief Sir Henry Dale, to the Medical Research Committee which had been set up the outbreak of war Part of Ewins' work was to range for the production of German drugs by British ms, and this association led in due course to his pointment as head of the chemical research department May & Baker He was responsible for the firm's search programme which in the '30s led to the development not only of sulphonamides but also of diamidine mpounds which have proved efficacious in tropical edicine Dr Ewins was elected F R S in 1943

A memorial service for Dr Maurice Mitman will be held at yce Green Hospital, Dartford, on Monday, Jan 13, at 3 P M ckets for the service can be had from the secretary, the Bow Arrow ospital, Dartford

Diary of the Week

JAN 5 TO 11

uesday, 7th

NIVERSITY OF LONDON
5.30 P M (London Hospital Medical College, E 1) Dr E Jacobsen (Copenhagen) Pharmacological Classification of Central Nervous Depressants
NSTITUTE OF DERMATOLOGY, Lisle Street, W C 2
5.30 P M Mr B E D Cooke Disorders of Buccal Mucosa

Wednesday, 8th

POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W 12
2 P M. Dr John Loutit Successful Transplantation of Homologous and Heterologous Tissue in the Experimental Mouse
INSTITUTE OF DISEASES OF THE CHEST, Brompton, S W 3
5 P.M. Dr Howard Nicholson Chronic Pulmonary Suppuration
INSTITUTE OF DERMATOLOGY
5.30 P M Dr Arthur Tickner Biochemistry of Hormones—Steroids
NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY, 64, St. James' Street, Nottingham
8 30 P M Dr Roger Ormrod Negligence
MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH
8 30 P.M. (Royal College of Surgeons 18, Nicolson Street, Edinburgh.) Dr J G M Hamilton, Prof J H Gaddum, Prof John Bruce Medicine in Russia

Thursday, 9th

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S W 1
5 P M Dr Matthew Thomson Some Aspects of Industrial Dermatitis (Watson Smith lecture)
LIVERPOOL MEDICAL INSTITUTION, 114, Mount Pleasant, Liverpool, 3
8 P M Lord Evans Significant Hypertension

Friday, 10th

POSTGRADUATE MEDICAL SCHOOL
10 A.M Mr J C. Barrett Multiple Primary Malignant Neoplasms
INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, Gray's Inn Road, W C.1
3.30 P.M. Mr Anthony Radcliffe Hoarseness

Appointments

CZYNIEWSKI J P, M D Lwow, D A anæsthetist (S.H.M O), East Cumberland group of hospitals
HAMSHAW, DORA, B.SC. Lond., M.R C.S, D C.H. assistant M O, York.
HARRISON, KENNETH, M.D Manc., F.R.C.S, D.L.O part-time consultant E N T surgeon Stockport and Buxton group of hospitals
JONES BRENDA, M.B Lpool D.P.H assistant M.O.H and school M O, Southport
SIMPSON J H, M.D Cantab, M R.C.P consultant physician with an interest in geriatrics, Exeter clinical area

Newcastle Regional Hospital Board
- HARRIS, HILDA R., M.B. Manc., M R.C.P.E., D.PATH assistant pathologist (S.H.M O) Hartlepools group of hospitals
- MCCLEMONT, JOHN, M.B Edin, D O.M.S consultant ophthalmologist, Darlington, Northallerton, and South West Durham groups of hospitals.
- MITCHELL, J C., M.D Aberd consultant pathologist, Newcastle upon Tyne group of hospitals

County Borough of West Hartlepool
- BISSET, JANET M, M.B. Edin., D C.H assistant M.O.H (maternity and child welfare)
- MILLIGAN H C., M.B. Edin, D P.H M.O.H.
- TERRY, S W W, M.B Madras D T.M & H, D.P.H deputy M.O.H.

Births, Marriages, and Deaths

BIRTHS

KAY—On Dec. 23 at the Cardiff Maternity Hospital to Beverley (nee Bryce) wife of Dr Michael Doveton Kay a son—Michael Graham Doveton

DEATHS

HALL—On Dec. 26 1957, at 16 Pilgrims Lane London N W.3 Edith May Hall M.D, F R C.S., F.R.C.O G

Notes and News

CLEAN AIR

IN 1306 a citizen was tried and executed in London for burning "sea cole", and though few of our modern reformers would favour so vigorous a remedy, the damage done by smoke to our health and economy has aroused the zeal and outcries of reformers since John Evelyn's *Fumifugium* of 1661, and even earlier The Coal Smoke Abatement Society was founded in London in 1899, and in 1929 it fused with the provincial Smoke Abatement League of Great Britain to form The National Smoke Abatement Society These societies have led the clean-air movement throughout the century, in the face of apathy, lack of financial support (for smoke abatement is not so romantic a cause as some less worthy), and even derision They began the study of air pollution that is now made under Government auspices, they pioneered training-schemes for boiler-operators, and they conceived the idea of smokeless zones Many of their views and policies were endorsed by the Beaver Committee, whose report led to the Clean Air Act

On Jan 1, the society changed its name to the National Society for Clean Air, in recognition of its widening scope, and became an incorporated body, it is a company limited by guarantee, without share capital, and with permission to omit the word "limited" from its title

The Beaver Committee estimated that the most heavily polluted areas could be made smokeless in ten to fifteen years if smoke-control areas totalling 300,000 acres could be established yearly, but the total for 1957 was 489, and the total projected for 1958 less than 10,000 acres Giving these figures, the society call attention to the need for continued and increasing instruction and publicity directed at authority and at the public, they encourage new members and donations to help in their important work, which includes the encouragement of research and of the application of new developments

GERIATRIC UNIT AT DUNDEE

At a cost of £45,000, the geriatric unit at Maryfield Hospital, Dundee, has been reconstructed It has been receiving patients since August, and it was visited by Princess Margaret on Dec 6

Accommodating 29 men and 30 women, on separate floors, it has for each sex four small wards and two sittingrooms Confused and incontinent patients can be segregated from the mentally alert, and patients are promoted to the better wards as soon as their condition improves sufficiently

The unit is complete in itself, with facilities for radiography, physiotherapy, and occupational therapy Full use can be made in addition of the specialist services of the general hospital. The local health authority has plans well advanced for the provision of halfway-house accommodation both by the reconstruction of existing buildings and by new building

The consultant physician in charge of the unit is Dr O Taylor Brown. The staff consists of a registrar, Dr A B Grant, and two house-officers The nursing staff, beside the two ward sisters, consists of staff nurses, student nurses, and nursing auxiliaries, with a proportion of male staff in the male ward. Dr Taylor Brown is lecturer in geriatrics to the University of St. Andrews and regular ward teaching takes place in the unit.

The Medical Society for the Care of the Elderly holds its spring meeting in Dundee on March 28 and 29, when a visit to this attractive unit will be part of the programme

HOSPITAL WORK ON TELEVISION

A series of programmes from regional hospitals is to be televised by the B B C from Feb 11 The first, dealing with poliomyelitis, will come from the Churchill Hospital [illegible] and the second, on cancer, from the Christie Hospital and Holt Radium Institute in Manchester The surgery of the circulation will be illustrated in three programmes—a [illegible] valvotomy at Queen Elizabeth Hospital, Birmingham, a [illegible] caval shunt from Bristol Royal Infirmary, and a third operation to be shown at Leeds Infirmary. The work of a cottage [illegible] will be displayed at Stratton Hospital, Cornwall, and a programme on psychiatry from the Southern General Hospital, Glasgow, will include a filmed sequence showing Crichton Royal Mental Hospital, Dumfries Wales will be represented by a programme on tuberculosis from Sully Hospital, Cardiff, and on pneumoconiosis from Llandough, Penarth A brain operation is to be shown at the Royal Infirmary, Edinburgh

The B B C hopes that members of the medical profession will see these programmes and would be pleased to have comments on them from doctors

CHRISTMAS QUIZ

Dr J B Gurney Smith points out that the " original set of posers " provided by Dr Ffrangcon Roberts in our issue of Dec 21 assign Dr Robert Bridges to the wrong hospital He trained at St Bartholomew's, not St Thomas's, and some of his early verses appeared in *Round the Fountain*

University of Cambridge

On Dec 14 the degree of M D was conferred on the following

P S Andrews, Edward Sharp, H H Stewart, S E Trickey

University of London

Dr E G L Bywaters, senior lecturer at the Postgraduate Medical School of London, has been appointed to the new Empire Rheumatism Council chair of rheumatology at the school We announced the endowment of the chair last week

Dr Bywaters, who graduated M B Lond with honours from the Middlesex Hospital in 1933, was appointed in the following year to a Mackenzie-Mackinnon research scholarship of the Royal College to study rheumatoid arthritis After visiting the United States with a Rockefeller fellowship he became clinical pathologist at the Bland-Sutton Institute of the Middlesex Hospital and later deputy director of the M R C unit at the Royal Victoria Infirmary, Newcastle-upon-Tyne, and besides his lectureship at the school he also holds at present the directorship of the research unit at the Canadian Red Cross Memorial Hospital at Taplow His published work includes papers on the metabolism of the joint spaces and during the late war he was one of the team which investigated the effect of crush injuries on renal function

University of Leeds

At recent examinations the following were successful

M D—R E Rossall
Ch M—M G Wilson
Ph D—J A Sharp
M B , Ch B—Geoffrey Hoyle (with second-class honours), T L Avery, Pamela M W Barker, J E Berry, Ian Bower, Barrie Breeze-Stringfellow, J M Brook, Charlotte N Capes, R B Dobson F E Eteng, Paul Foggitt, L F Gendall, T M Hall, Joyce M Handby, D A W Hopkinson, J L Horner, D A House, H A Hunt, R C Ingrey-Senn, P J Knapton, Margaret E Lane D R Liddle, M D McGrath, J C Nicholson, John Norman, Aleksandra M Schwetz, Neville Seymour, J M Sinclair, P Yuk Fen Taikie, Eifion Treharne, Marion E Tyler, Sarah A Williams

University of Bristol

At recent examinations the following were successful

M B , Ch B—M G Addy, A A Codd, J C G Cole, J S Edmondson, R R Gibbins, D H Howton, Osafo Lartey, J G Meadows, K J Roper, G A Russell, R F Weeks, R C Williams

University of Liverpool

At a special congregation on May 7 to mark the opening of the new medical school by Queen Elizabeth the Queen Mother the honorary degree of LL D will be conferred on Lord Adrian, Sir David Campbell, and Sir Allen Daley

University of Edinburgh

Mr J I P James has been appointed to the George Harrison Law chair of orthopædic surgery in succession to Sir Walter Mercer He is expected to take up his appointment in the spring

Mr James who is 44 qualified from University College Hospital, London, in 1934 and two years later took the F R.C.S In 1941 he became part-time registrar in the Royal National Orthopædic Hospital London, and a year later surgical registrar at U C H The same year he obtained the M S Lond In 1943 he joined the R.A M C and served with a special airborne force as a forward surgeon with guerilla forces in Yugoslavia and as orthopædic surgeon to the forces in Greece When he was demobilised he held the rank of lieut.-colonel and was officer commanding the surgical division of a general hospital Since 1946 he has been orthopædic surgeon at the Royal National Orthopædic Hospital and he is also assistant director of studies at the Institute of Orthopædics, London University and civilian consultant orthopædic surgeon to the Royal Navy In 1947-48 with a Rockefeller fellowship he worked in orthopædic centres at Boston, New York, and San Francisco In 1956 he gave a Hunterian lecture on paralytic scoliosis and his other published work includes papers on the treatment of curvature of the spine and on reconstructive surgery of the hand

Airborne Medical Society

A meeting of this society will be held on Friday, Jan. 31, at 5 30 p m at St Mary's Hospital, London, W 2

Institute of Dermatology, London

A semi permanent exhibition on the normal epidermis and some precancerous conditions by Dr H Haber, will be held from Jan 1 to 17 at the institute, Lisle Street, W C 2

The Prime Minister and the Whitley Award

On Dec 23 Mr Harold Macmillan received a deputation led by Mr Ben Smith, chairman of the staff side of the General Council of Whitley Councils, and explained that under present economic conditions it was not possible to lift the Ministerial veto on a 3% increase for administrative and clerical staff in the National Health Service

British Journal of Tuberculosis

The editor of this journal, Dr Philip Ellman, is to have an assistant editor, and Mr J R Belcher has been appointed Prof Charles Cameron, Dr Maurice Davidson, and Dr Reginald Ellis are retiring from the editorial board and Dr Frank Scadding, Dr I W Grant, and Dr R Y Keers have been appointed in their place Prof O L Wade is to be an additional representative on the board

Spastics in the West of Scotland

A year ago a new residential school, Scotscraig, was opened in Paisley under the direction of the Scottish Council for the Care of Spastics The Council's first school, Westerlea, was started in Edinburgh in 1947 When extensions planned for the Paisley school have been completed, it should have enough places to educate and treat suitable children from the West of Scotland

At present it has 8 resident pupils and 4 day pupils, 17 other children who go to school elsewhere or are below school age, attend for physiotherapy or speech therapy Future plans include an extension of outpatient treatment by a team of therapists visiting outlying centres and a nursery school for preschool children Children are selected by a screening panel consisting of an orthopædic surgeon, a pædiatrician, a child psychiatrist, and an educational psychologist Arrangements for screening are made with the social worker, Scotscraig, Park Road, Paisley

Medical Research Council

The Council invite applications for the following fellowships for 1958–59

Fellowships in Clinical Research—The Council are offering a further series of fellowships in clinical research, tenable at centres in the United Kingdom These fellowships are open to suitably qualified medical graduates who wish to prepare for a career in clinical research

Rockefeller Travelling Fellowships—These fellowships are intended for graduates resident in this country who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad before taking up appointments for higher teaching or research in the United Kingdom

Dorothy Temple Cross Fellowships in Tuberculosis—These fellowships offer special opportunities for study or research to British doctors who intend to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis ' The fellowships will, as a rule be awarded to candidates who wish to make their studies or inquiries elsewhere than in the United Kingdom

Alexander Pigott Wernher Fellowships in Ophthalmology and Otology—These fellowships are intended for doctors who are likely to profit by a period of work in ophthalmology or otology at a centre abroad before taking up positions for higher teaching and research in these branches of medical science The awards will normally be tenable for one year

United States Public Health Service Research Fellowships—A limited number of these fellowships are being offered to highly qualified scientists from outside the United States to work in the medical and biological laboratories of the United States British doctors should apply in the first instance to the Medical Research Council

French Government Exchange Scholarships—Under the terms of a reciprocal arrangement with the Centre National de la Recherche Scientifique two scholarships tenable at research institutions in France are offered to British workers in medical science The scholarships will normally carry a maintenance allowance of 50,000–70,000 francs a month

All the fellowships provide for the payment of a maintenance allowance at the rate of £650 per annum for a single fellow or £900 per annum for a married fellow ($3000 and $4200 respectively if the fellowship is held in the United States) Allowances are made for travelling and other approved expenses Forms of application for these fellowships may be had from the secretary of the Council, 38, Old Queen Street, London, S W 1, with whom applications must be lodged by March 1 (March 31 for the Pigott Wernher fellowships and the French scholarships)

Mr A L d Abreu is visiting Peru from Jan 5 to Feb 6 under the sponsorship of the British Council He will give twelve lectures on thoracic surgery at the tuberculosis hospital at Lima

The Lancet · Saturday 11 January 1958

REGULATION OF BODY TEMPERATURE IN HEALTH AND DISEASE*

SIR GEORGE PICKERING
M.A., M.D. Cantab., F.R.C.P., Hon. F.A.C.P.
REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD

(concluded from p. 9)

MY first lecture was concerned with the mechanisms with which a healthy man regulates his body temperature. Now I wish to consider briefly the very low and very high temperatures which may be produced by breaking through this regulating mechanism, and to consider more fully the problem of fever which results from a disturbance in the regulating mechanism.

Hypothermia

It has been known for a long time (Boyle 1683) that fish may be imprisoned in ice, and may even become partly frozen, and yet recover when the temperature is raised. With the approach of winter some mammals (e.g., the marmot and the dormouse) retire to their burrows, curl up, and become drowsy, their body temperature falls to a little above that of their surroundings, and their heart-rates, respiration-rates, and metabolic rates fall to low levels. From warm-blooded they have changed to cold-blooded animals. The capacity to do this is widely distributed in mammals, being found in rodents (beavers), insectivores (hedgehogs), and carnivores (bears). It is rare in birds, but the "Poor Will" of the Western United States is said truly to hibernate (Fisher 1953).

Dr. Audrey Smith (1956) has shown that the hamster can be cooled to temperatures below freezing-point. When the temperature of the parietes falls to about −5°C, ice crystals form, the process of supercooling is arrested, and the temperature rises. As a consequence of the freezing of water, the electrolyte concentration of the remaining fluid rises, and, when it has doubled in the extracellular fluid, the cells are irreversibly damaged (Lovelock and Smith 1956). Even though superficial parts of the hamster form a shell of ice crystals, the animal may recover if it is gently warmed—e.g., by immersion in warm water—particularly if it has frozen progressively for not longer than 50 minutes, but less often if it has crystallised after supercooling below −3.5°C. The frozen animal has, of course, no heart-beat and no respiration, and artificial respiration is required during warming.

Rats do not hibernate. Andjus (1951), however, showed that a small proportion of these animals cooled to between 0 and +2°C could also be reanimated after heart and breathing had stopped for 40–50 minutes, and improvement of technique brought about the survival of 75–100% of animals so cooled (Andjus and Smith 1955). The learning of rats so cooled and reanimated was definitely impaired when cooling had proceeded to between +1 and 0°C, but no impairment was demonstrated when the lowest temperature reached was between +13.4 and +18.5°C (Andjus et al. 1956).

The theoretical and practical importance of these observations needs no emphasis. Here in fact is a breaking through of the barrier between Bernard's "*la vie constante*" to "*la vie oscillante*" and even to "*la vie non-manifestee*". Moreover it is becoming increasingly evident that, at low temperatures, operations, particularly those involving heart, large blood-vessels, and brain, are possible that would have had disastrous results at normal temperature. A large literature has grown up on hypothermia or artificial hibernation in man, and I shall not attempt to review it here. I shall only make four points.

(1) The practical difficulty in cooling men is to break through the defences of the body; the most effective means is to give an anæsthetic, which (as we have seen) has been shown to interrupt at some point or points the reflex arcs which protect against cooling, particularly by shivering.

(2) Consciousness generally seems to be clouded or lost at rectal temperatures between 29 and 31°C.

(3) At temperatures below 30°C glucose is metabolised slowly or not at all (Wynn 1954).

(4) Finally and most important, the lethal temperature seems to be between 25 and 27°C, when ventricular fibrillation occurs. The exact mechanism by which ventricular fibrillation is precipitated in cold men is thus the outstanding practical problem, if the full possibilities of this line of treatment are to be developed.

Hyperthermia

It has also long been known that, in very hot weather, particularly after exposure to strong sun, men may become comatose and die. Medicine, in its omniscience, was of course at hand with an explanation, and this illness was attributed to the actinic rays of the sun striking through the back of the neck to the vital centres in the medulla. Hence the pith helmet and those cloths that draped the back of the helmet in India a century ago. It is known now that this illness is heatstroke, a breakdown of the regulating devices of the body with the result that the temperature rises usually above 106°F. I know of three good accounts, that of Lambert (1897) describing an epidemic in New York, that of Ferris et al. (1938) describing an outbreak in Cincinnati, and that of Ladell, Waterlow, and Hudson (1944) describing their experiences with British and Commonwealth troops in the Middle East.

Of the Cincinnati patients only seven were under 50 years old, and most were exposed to the highest temperatures—e.g., living in a top flat under a flat roof which got much heated by the sun. Absence of sweating was noted in all, most were in coma and incontinent of fæces. When they were treated with ice-water applied to the skin, there was a rapid fall of temperature, consciousness being regained about 106–107°C, when goose-skin was also frequently noted. The sodium-chloride level in the blood was normal. The cessation of sweating was noted to be a common precipitating factor in these cases, as it was in those of Ladell et al. (1944).

Lambert (1897) found in the New York epidemic that every patient with a temperature of 110°F or over was completely comatose. Of seventy-three patients admitted to hospital and subsequently traced, three were found to be insane.

These observations may be compared with those on therapeutic hyperthermia, at one time used to treat syphilis and gonorrhœa, described by many workers—e.g., Wallace and Bushby (1944). The aim of such treatment was to achieve a temperature of 106°F for 8 hours. Most of the patients became disorientated, and many showed herpes labialis on recovery. These are two of the striking features of lobar pneumonia, often attributed to that (to me mysterious) state "toxæmia" but apparently attributable simply to the effect of temperature. Arterial anoxia and bilirubinæmia were common. Lambert noted anæmia as a common sequel of sunstroke in the New York epidemic.

---

* The Croonian lectures for 1957, delivered on May 14 and May 16 before the Royal College of Physicians of London.

Fever

By far the most important of the disturbances of body temperature is fever, which may be defined as a raised central temperature consequent on a disturbance of the thermotaxic mechanism

One cause of fever may be disposed of at once—namely, a lesion of the central nervous system, particularly of the basal ganglia These lesions presumably destroy part of the central receptors or their connections In view of the results of experiments on animals it is rather surprising that such lesions have never been observed to produce falls but only rises in body temperature These rises are often extreme Thus of Bryant's hundred cases of hyperpyrexia (over 106°F) twenty-two were due to brain lesions, and all those patients died Little more can be learnt from such cases The commonest lesion is cerebral hæmorrhage, which usually causes extensive disruption of the brain, the basal ganglia are generally involved, and rupture into the ventricles is common

Causes

In the remaining, and much more numerous, instances, fever is the result of a functional disturbance of the thermotaxic mechanism The commonest causes are (1) infections or infestations, and (2) lesions which destroy tissues

Infecting agents include viruses (e g , poliomyelitis), bacteria (e g , pneumonia), protozoa (e g , malaria), and fungi (e g , actinomycosis) Even the nematode worms may be involved, invasion of the tissues by *Trichinella spiralis*, or of the lungs by ascaris, may produce fever, associated in each case with a large increase in the eosinophil cells of the blood In the absence of infections, fever due to lesions causing tissue destruction is usually slight, such lesions are infarction (e g , of the heart), malignant tumours (particularly when the growth is extensive or metastasising in liver), and gout

Because of these two types of lesion causing it, the mechanism of fever has been sought in the chemical constituents of invading microorganisms, on the one hand, and of the body cells of the host on the other Here we may note that fever has other causes whose nature is obscure Thus rheumatic fever is currently conceived to represent an immune reaction between the antigens of a particular strain of streptococcus (Lancefield group A, B hæmolytic) and the antibodies of the host Half a century ago this disease was a common cause of hyperpyrexia, comprising 6% of Bryant's cases, and being the commonest cause in the wards of Guy's Hospital after nervous lesions and pyæmia Another curious instance is hæmorrhage, a rise of temperature up to 100 or 101°F is common after gastrointestinal bleeding

Of these instances of naturally occurring fever, by far the most carefully investigated is malaria

Characteristically, paroxysms of fever occur on the third day (every 48 hours) in benign and malignant tertian malaria (*Plasmodium vivax* and *falciparum*) or on the fourth day in the quartan form (*P malariæ*) These intervals correspond to the times taken for the merozoites to invade the red cells, subdivide within them, and finally break through the red-cell envelope into the bloodstream The onset of fever is thought to correspond approximately to the rupture of the red cells and the entry of the merozoites into the bloodstream

Virchow (1854) conceived of fever as a weakness—a failure to control heart, blood-vessels, and metabolism through the moderating centre Traube (1864) discovered that in fever the elimination of nitrogen is increased He supposed that this was secondary to a circulatory disturbance, that a fever-producing agent produced, through the tonic vasomotor nerves, contraction of the peripheral arterioles, with a consequent decline in surface temperature and rise in deep temperature Von Liebermeister (1875) developed Traube's hypothesis and concluded from his experiments that, in fever as in health constancy of body temperature is ensured by the adaptation of heat production to discharge, and that in fever the body temperature is regulated in the same way as in health, except that the norm is higher In general Von Liebermeister's concept of the nature of the disturbance that constitutes fever is widely accepted still As we shall see, it explains many of the facts, but new data have become available that lie entirely outside his hypothesis With this introduction we may look more closely at the established facts

Three Phases

It is customary to divide a fever into three phases (1) the phase of rising temperature, the chill or ague, (2) the phase of steady pyrexia, the fastigium or flush, and (3) the phase of falling temperature, the sweating phase or defervescence The first and last phases are most easily studied in brief bouts of fever whose onset and duration are predictable Such are malaria and the fever produced by injection of pyrogens

It is clear from bedside observation that the rise of temperature during the *chill* is due both to decreased heat loss and to increased heat production Thus, at the onset of the chill, the blood-vessels of the skin constrict and the surface temperature falls, the patient feels subjectively cold, goose-skin develops, and he begins to shiver At this stage he will, if he can, retire to bed with a hot-water bottle and many blankets In a patient with quotidian ague Sydney Ringer (1859) found that the temperature recorded in the axilla began to rise before there was a subjective sensation of cold In fever produced by incubation of bacterial pyrogen with blood Gerbrandy, Cranston, and Snell (1954) found that a sharp vasoconstriction in the hand preceded the rise in mouth-temperature by about 3 minutes, the rectal temperature beginning to rise some 6 minutes later That heat production is increased during the chill was first shown by Von Liebermeister (1875) and confirmed by Barr and DuBois (1918)

The *fastigium* is most easily studied in pneumonia or in typhoid where the temperature remains high for several successive days It shows the same diurnal variations as in health, the peak being reached in the early evening and the trough in the early morning, but the fluctuations are usually larger It is from this phase comes the chief evidence for Von Liebermeister's hypothesis

Stern (1892) found that, when the body was immersed in a hot bath, sweating began after the same rise of temperature (0 1–0 8°C) in febrile as in normal people, conversely, immersion in a cool bath produced shivering after similar falls Schwenkenbecher and Tuteur (1907) observed that food produced similar increases in water loss from the skin in normal people and in patients with typhoid In continuous fever they observed that the water loss from the skin is increased Cecil, Barr, and DuBois (1922) observed that in continuous fever both heat production and heat elimination are increased, the increase in heat production above the normal averaging about 13% of basal per 1°C rise in body temperature

The *defervescence* or phase of fall of temperature is seen at its most striking in the crisis of pneumonia and in the sweating stage of the malarial attack The patient feels very hot, he flings off his bedclothes and begins to sweat profusely. Clearly the fall of temperature is due to the mobilisation of all the mechanisms that increase heat loss.

In general, these phenomena can be interpreted in terms of Von Liebermeister's hypothesis. If we assume that, in the first phase, the setting of the thermotaxic mechanism is raised, we should expect the events during this phase to resemble those produced by exposing a healthy person to cold. Again during the fastigium temperature is regulated at a new and high level, and the usual defences are mobilised against a deviation up or down. Finally, the defervescence would be ascribed to a reduction in the level at which the mechanism is set, the response of the body should mimic that produced by exposure to heat, as it does. Nevertheless the methods used to test the hypothesis in the past have been relatively crude, and it is to be hoped that an opportunity will be found to see whether the central and peripheral receptors behave quantitatively in fever as Snell and Cooper have found them to behave in health.

Most of the phenomena of fever can be explained on this hypothesis or the effect of the raised temperature itself. Thus a rise in heart-rate and respiratory rate is produced by heating the body—though the relatively slow pulse in typhoid and high respiratory rate in pneumonia are exceptions. Again, the increased metabolic rate, together with anorexia, may largely explain the increased excretion of nitrogen and the tendency to muscular wasting, though, as Wright (1950) has emphasised, the major defence reactions of the body also involve large syntheses of protein. However, one set of vascular responses is now known that cannot be so explained, and to that we may now devote our attention.

Responses Unrelated to Thermotaxis

These responses were discovered accidentally by Homer Smith and his colleagues during investigations on the behaviour of the kidney: a sample of inulin, which they were using to estimate the glomerular filtration-rate, proved to be pyrogenic, and they were surprised to find that it produced a pronounced increase in the apparent renal blood-flow. Further and detailed investigation showed that the initial phase of the febrile response, the chill, is accompanied by a rise of blood-pressure and a decrease in glomerular filtration-rate and in renal plasma-flow. The phase of sustained pyrexia is accompanied by a fall of arterial pressure and a slight rise in glomerular filtration-rate and a much larger increase in renal blood-flow (Goldring et al. 1941). The fall of arterial pressure is much greater in persons with high blood-pressure, as indeed is true with most responses (Pickering 1955). Now, the fall in arterial pressure and the renal vasodilatation are not due to the rise in body-temperature, nor are they an essential component in producing it, for they both occur after the injection of a bacterial pyrogen, even though the fever is prevented with amidopyrine. These vascular responses thus seem to represent another effect of bacterial pyrogens, distinct from their effect on the thermotaxic mechanism.

Pyrogens

It is now apposite to turn our attention to the problem of pyrogens—i.e., substances which produce fever on parenteral injection. These substances have been sought in many places and found in two—namely, in bacteria, and in polymorphonuclear leucocytes.

The history of the investigation of bacterial pyrogens is fully reviewed by Bennett and Beeson (1950). Intravenous injection of the dead bodies of most gram-negative bacteria produces fever. Contamination with bacterial debris is now recognised as the cause of water fever, of salt fever, and of sugar fever (i.e., of pyrexia following intravenous injection of these fluids), and, as Hort and Penfold (1912) showed, the contaminating agents are of such a size that they pass a filter candle but not the gelatin filter devised by Martin. Lüderitz and Westphal (1952) have identified the pyrogen of *Escherichia coli* as a lipopolysaccharide of high molecular weight and containing 74% of phosphorylated polysaccharide and 26% of lipoid. The sugars obtained by hydrolysis of the polysaccharide include rhamnose, xylose, glucose, galactose, and *N*-acetyl hexosamine. 0·1 μg of this substance injected intravenously is enough to produce fever in man. Like other bacterial pyrogens, this substance is not dialysable, it is not destroyed by boiling or autoclaving but is destroyed by dry heat at 160°C.

Oddly enough, no pyrogens have yet been found in gram-positive cocci. Thus, the bodies of dead pneumococci injected intravenously produce no fever (Bennett 1956c), despite the fact that the fever accompanying pneumococcal infection is one of the most intense encountered in man.

Because, as we have seen, mild or moderate fever is a common accompaniment of tissue destruction in man, several workers have sought pyrogens in tissue extracts. One of the first to report success was Menkin (1945), who showed that extracts of pus were pyrogenic, and named the active substance "pyrexin". However, the sample which Bennett and Beeson (1953b) investigated behaved more like a bacterial pyrogen, and the exact status of pyrexin remains uncertain.

The most thorough of such investigations is that of Bennett and Beeson (1953a), who, taking great care to avoid bacterial contamination, made saline extracts of various tissues in the rabbit, and found only one tissue that produced fever—namely the polymorphonuclear leucocytes. These they obtained from the buffy coat of the blood and from the peritoneal exudate induced by injecting physiological saline solution four hours previously. The pyrogenic agent found in leucocytes is quite different from that found in bacteria. Like that, it is not dialysable, but it is destroyed by boiling, but not by trypsin, chymotrypsin, or ribonuclease (Bennett and Beeson 1953b).

Again, oddly enough, no pyrogen has yet been obtained from human leucocytes. Cranston, Goodale, and Wendt, working in my laboratory, have not yet been able to produce fever with extracts of human leucocytes made by shaking them with glass beads, by freezing and thawing them, or by lysing them with water.

Mechanism by which Bacterial Pyrogens Produce Fever

When a bacterial pyrogen is injected intravenously into an animal, fever does not begin at once but only after a latent period of about quarter of an hour in the rabbit and 50 minutes in man. This, together with the fact that fever is known to occur in man in the absence of bacterial infection, led to search for a common factor, such as an intermediate substance produced by the interaction of bacterial pyrogens on the tissues of the body. Menkin's work has been noted. Beeson (1947) observed that, after large doses of bacterial pyrogen, little trace of any pyrogen was found in blood removed 8–10 minutes later, at 4–6

Fever

By far the most important of the disturbances of body temperature is fever, which may be defined as a raised central temperature consequent on a disturbance of the thermotaxic mechanism

One cause of fever may be disposed of at once—namely, a lesion of the central nervous system, particularly of the basal ganglia These lesions presumably destroy part of the central receptors or their connections In view of the results of experiments on animals it is rather surprising that such lesions have never been observed to produce falls but only rises in body temperature These rises are often extreme Thus of Bryant's hundred cases of hyperpyrexia (over 106°F) twenty-two were due to brain lesions, and all those patients died Little more can be learnt from such cases The commonest lesion is cerebral hæmorrhage, which usually causes extensive disruption of the brain, the basal ganglia are generally involved, and rupture into the ventricles is common

Causes

In the remaining, and much more numerous, instances, fever is the result of a functional disturbance of the thermotaxic mechanism The commonest causes are (1) infections or infestations, and (2) lesions which destroy tissues

Infecting agents include viruses (e g , poliomyelitis), bacteria (e g , pneumonia), protozoa (e g , malaria), and fungi (e g , actinomycosis) Even the nematode worms may be involved, invasion of the tissues by *Trichinella spiralis*, or of the lungs by ascaris, may produce fever, associated in each case with a large increase in the eosinophil cells of the blood In the absence of infections, fever due to lesions causing tissue destruction is usually slight, such lesions are infarction (e g , of the heart), malignant tumours (particularly when the growth is extensive or metastasising in liver), and gout

Because of these two types of lesion causing it, the mechanism of fever has been sought in the chemical constituents of invading microorganisms, on the one hand, and of the body cells of the host on the other Here we may note that fever has other causes whose nature is obscure Thus rheumatic fever is currently conceived to represent an immune reaction between the antigens of a particular strain of streptococcus (Lancefield group A, B hæmolytic) and the antibodies of the host Half a century ago this disease was a common cause of hyperpyrexia, comprising 6% of Bryant's cases, and being the commonest cause in the wards of Guy's Hospital after nervous lesions and pyæmia Another curious instance is hæmorrhage, a rise of temperature up to 100 or 101°F is common after gastrointestinal bleeding

Of these instances of naturally occurring fever, by far the most carefully investigated is malaria

Characteristically, paroxysms of fever occur on the third day (every 48 hours) in benign and malignant tertian malaria (*Plasmodium vivax* and *falciparum*) or on the fourth day in the quartan form (*P malariæ*) These intervals correspond to the times taken for the merozoites to invade the red cells, subdivide within them, and finally break through the red-cell envelope into the bloodstream The onset of fever is thought to correspond approximately to the rupture of the red cells and the entry of the merozoites into the bloodstream

Virchow (1854) conceived of fever as a weakness—a failure to control heart, blood-vessels, and metabolism through the moderating centre Traube (1864) discovered that in fever the elimination of nitrogen is increased He supposed that this was secondary to a circulatory disturbance, that a fever-producing agent produced, through the tonic vasomotor nerves, contraction of the peripheral arterioles, with a consequent decline in surface temperature and rise in deep temperature Von Liebermeister (1875) developed Traube's hypothesis and concluded from his experiments that, in fever as in health, constancy of body temperature is ensured by the adaptation of heat production to discharge, and that in fever the body temperature is regulated in the same way as in health, except that the norm is higher In general Von Liebermeister's concept of the nature of the disturbance that constitutes fever is widely accepted still As we shall see, it explains many of the facts, but new data have become available that lie entirely outside his hypothesis With this introduction we may look more closely at the established facts

Three Phases

It is customary to divide a fever into three phases (1) the phase of rising temperature, the chill or ague, (2) the phase of steady pyrexia, the *fastigium* or flush, and (3) the phase of falling temperature, the sweating phase or defervescence The first and last phases are most easily studied in brief bouts of fever whose onset and duration are predictable Such are malaria and the fever produced by injection of pyrogens

It is clear from bedside observation that the rise of temperature during the *chill* is due both to decreased heat loss and to increased heat production Thus, at the onset of the chill, the blood-vessels of the skin constrict and the surface temperature falls, the patient feels subjectively cold, goose-skin develops, and he begins to shiver At this stage he will, if he can, retire to bed with a hot-water bottle and many blankets In a patient with quotidian ague Sydney Ringer (1859) found that the temperature recorded in the axilla began to rise before there was a subjective sensation of cold In fever produced by incubation of bacterial pyrogen with blood Gerbrandy, Cranston, and Snell (1954) found that a sharp vasoconstriction in the hand preceded the rise in mouth-temperature by about 3 minutes, the rectal temperature beginning to rise some 6 minutes later That heat production is increased during the chill was first shown by Von Liebermeister (1875) *and confirmed* by Barr and DuBois (1918)

The *fastigium* is most easily studied in pneumonia or in typhoid where the temperature remains high for several successive days It shows the same diurnal variations as in health, the peak being reached in the early evening and the trough in the early morning, but the fluctuations are usually larger *It* is from this phase comes the *chief* evidence for Von Liebermeister's hypothesis

Stern (1892) found that, when the body was immersed in a hot bath, sweating began after the same rise of temperature (0 1–0 8°C) in febrile as in normal people, conversely, immersion in a cool bath produced shivering after similar falls Schwenkenbecher and Tuteur (1907) observed that food produced *similar increases in* water loss from the skin in normal people and in patients with typhoid In continuous fever they observed that the water loss from the skin is increased Cecil, Barr, and DuBois (1922) observed that in continuous fever both *heat* production and heat *elimination* are increased, the increase in heat production above the normal averaging about 13% of basal per 1°C rise in body temperature

The *defervescence* or phase of fall of temperature is seen at its most striking in the crisis of pneumonia and in the sweating stage of the malarial attack The patient *feels* pyrogenic activity both in its polymorphs and in the fluid in which they lie In these animals, unlike those with sterile xudates, pyrogenic activity is present in thoracic-duct lymph, none was demonstrable, however, in the circulating blood It is therefore suggested that the fever produced by pneumococcal infection is due to the release from leucocytes of their pyrogenic material and its absorption into the blood-stream (Bennett 1956c)

Armin and Grant (1957) have shown that, after the ntravenous injection of an *Esch coli* vaccine, the denervated ear of the rabbit shows two phases of constriction—one at about 5 minutes, and the other at about an hour, after the injection The first is probably due to the release of a histamine-like substance, and the second to release of substances like adrenaline and 5-hydroxytryptamine It is interesting that the delayed release occurs at a time when the normal ear (which is less sensitive to chemical stimuli) is vasodilated through nervous action

Effect of Pyrogens in Man

The first investigation of the initial process in the action of bacterial pyrogens in man was that of Gerbrandy, Cranston, and Snell (1954) Using both a killed *Esch coli* preparation ('Pyrifer') and a polysaccharide fraction obtained from pseudomonas ('Piromen'), they found that intravenous injection in normal subjects produced a fall of heat elimination from the hand, a rise in mouth temperature, and a rise in rectal temperature, after latent periods of 76 2, 71 1, and 73 5 minutes respectively (fig 6) When the same dose of pyrogen was incubated for $2^1/_2$–$3^1/_2$ hours at 37°C in 17–250 ml of the person's own blood, the latent periods of the responses were 16 5, 19 2, and 25 5 minutes respectively

These are large differences, about 50–60 minutes, and it seems even clearer in man than it was in the rabbit that the initial process in the action of a bacterial pyrogen is with a component of the blood Cranston, Goodale, Snell, and Wendt (1956) have shown that the tissue component is probably the polymorphonuclear leucocyte Unlike that of the rabbit, human plasma or serum incubated with bacterial pyrogen neither accelerates nor augments the fever that ensues after its injection In fact both serum and plasma reduce the febrile response, the effect being destroyed by previously heating serum to 56°C for 30 minutes (Goodale et al 1956) This effect may perhaps be correlated with the evidence of Rowley et al (1956) that normal serum splits bacterial polysaccharide, an effect likewise inhibited by previously heating the serum to 56°C

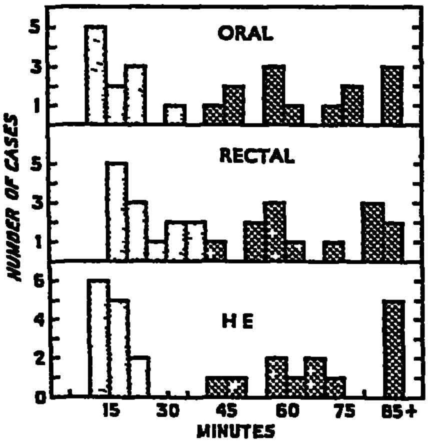

Fig 6—Latent periods between injections of pyrogen and changes in oral and rectal temperature and in elimination of heat from hand (H.E. stippled, pyrogen incubated in fresh blood hatched, control injections of pyrogen Gerbrandy et al (1954)

If, on the other hand, pyrogen is incubated with the cellular fraction of the blood and then injected, the fever is of rapid onset By using fractions containing different proportions of red cells, white cells, and platelets, Cranston et al (1956) show that there is a clear correlation between the incidence of fever of rapid onset and the number of white cells in the preparation, but none with the numbers of red cells or of platelets

If bacterial pyrogen is incubated with a preparation of white cells suspended in saline solution, the rapidly acting pyrogenic substance is found in the supernatant fluid after spinning off the cells Its chemical properties can thus be investigated It has been shown that it does not dialyse, that it is precipitated by saturation with ammonium sulphate, and that it is destroyed by heating to 70°C for 30 minutes The properties of this endogenous pyrogen are thus in a broad way similar to those of the pyrogen obtained by Bennett and Beeson (1953a and b) from the normal leucocytes of the rabbit It is more likely to be derived from the leucocytes (by the action on them of bacterial pyrogen) than to be derived from the bacterial pyrogen itself On the other hand, if this view is correct, incubation with pyrogen should produce some morphological change in the white cells, but no such change has yet been observed, nor are the white cells destroyed Again, one would expect that a similar substance might be liberated when white cells are lysed, but this has not been demonstrated

Discussion

The evidence now seems strong that, sometimes at least, fever in man is due to the release of a substance ("endogenous pyrogen") from leucocytes, through the action of bacterial pyrogens on them. In the rabbit the tissue reactant seems to be found in plasma or serum In the rabbit pyrogenic substance can be extracted from normal leucocytes and seems to have properties similar to those of the endogenous pyrogen released from human white cells by bacterial pyrogen As yet no similar substance has been extracted from normal human white cells

The phenomenon of tolerance suggests that, in man and the rabbit, the formation of endogenous pyrogen is a necessary intermediate step between bacterial pyrogen and fever It is tempting to suppose that such an intermediate step is always necessary, but much work remains to be done before such a proposition can be either affirmed or denied The endogenous pyrogen most probably acts on certain cells in the central nervous system, modifying their behaviour in such a way that the effect of cold on the peripheral and central receptors is mimicked It may act on the vessels of the kidney, producing the peculiar changes already discussed, but this again is to go beyond the evidence

The considerable interval between the entry of endogenous pyrogen into the blood-stream and the onset of fever suggests the formation of a further intermediate substance The latent period may, however, represent the time taken for the endogenous pyrogen to pass from the blood plasma to the site of action in the cell, for its chemical properties indicate that it is a large molecule, and it may have a fair distance to travel

* * *

The function of hypothesis is to stimulate experiment, and these remarks are chiefly justified in that sense It must be clear to the reader that the problem of fever, hitherto so resistant to scientific inquiry, is now beginning minutes pyrogenic activity was always considerable Farr and LeQuire (1950) and LeQuire (1951) agreed but found that, when typhoid vaccine was incubated with citrated plasma before injection, the fever produced by its intravenous injection into recipient rabbits was hastened and augmented compared with that produced by incubating the pyrogen with saline solution They attributed the effect to aggregation of the vaccine, which protected it from removal by the reticulo-endothelial system Such are the observations from which the new developments in our understanding of fever stem

Before describing these experiments it is necessary to explain the difference between the tolerance and the immunity which occur after repeated injections of pyrogen If a given dose of pyrogen is injected daily, the amount of the fever (measured by the area of the curve of raised temperature) gradually lessens and after about a week or 10 days becomes small and thereafter remains unchanged The animal is said to be tolerant Left alone for 3 weeks and then reinjected, the animal gives a response which is equal in size to its original response The tolerance has disappeared

Now, pyrogens are chemically rather like antibodies polysaccharides are major constituents of both of them Tolerance is not, however, due to the formation of specific immune antibodies, for the following reasons (1) its rate of development during injection and its persistence after injection are not parallel to the amount of immune antibodies in the blood, and (2) it is not specific an animal that has become tolerant to a bacterial pyrogen derived from one species gives a reduced response to pyrogen derived from a related, but not identical, organism

With this digression we may return to our main theme The story has been developed by investigations in the rabbit and in man, and, since the facts elucidated differ materially in the two species, it will be necessary to treat them separately

Effect of Pyrogens in Rabbits

Using pyrogen derived from *Proteus vulgaris*, Grant and Whalen (1953) found that fever after intravenous injection began earlier (12 minutes) after large doses (5 µg upwards) than after smaller doses (26 minutes for 1 µg) These responses had an early peak and a later peak When large doses (100 µg) were injected intravenously, citrated blood withdrawn during the subsequent 3 hours was also pyrogenic when blood was withdrawn 60-180 minutes after injection, the febrile response was hastened and the secondary peak tended to be smaller or absent Grant and Whalen also showed that incubation of the pyrogen with citrated or heparinised plasma before injection diminished the latency of the ensuing fever They attributed these effects to the interaction between bacterial pyrogen and plasma, leading to the formation of a new and more rapidly acting endogenous pyrogen Grant (1953) showed that this capacity to form endogenous pyrogen is lost in the tolerant animal Thus incubation of pyrogen with plasma from normal animals produces an augmented and quickened response in tolerant recipients On the other hand, incubation of pyrogen with plasma from tolerant animals neither accelerates nor augments the response in tolerant recipients

These results have been confirmed and amplified by Atkins and Wood (1955)

They investigated the responses to typhoid vaccine in three groups of rabbits

(1) *Unsensitised* animals that had received no previous injection.

(2) *Sensitised* animals that had received one or two previous injections at intervals of not less than three weeks, with three to five weeks elapsing before the final test

(3) *Tolerant* animals injected intravenously daily for 7-8 days and tested within 24 hours of the last injection

Blood was withdrawn by cardiac puncture 5, 30, 60, and 120 minutes after intravenous *injection of the vaccine and allowed* to clot, 50-60 ml of serum warmed to 37°C was injected intravenously to recipient rabbits next day In the blood of the *unsensitised rabbits* the resulting fever indices (the areas enclosed by the curves of raised temperature) fell to half their initial value at 30 minutes and thereafter remained unchanged. In the *sensitised* rabbits the initial (5 minutes) value was less than half that of controls, and all pyrogenic activity had gone at 30 minutes, thereafter reappearing, the value at 90 minutes *being similar* to that at 5 minutes The blood of *tolerant* rabbits showed no significant activity at any time

As Grant and Whalen (1953) had found, the blood withdrawn at 120 minutes produced a more rapid response than that withdrawn at 5 minutes Atkins and Wood (1955) think that some of this secondary pyrogen may come from injured leucocytes, firstly because bacterial pyrogen produces a leucopenia which precedes the fever, and secondly because Braud et al (1955) have shown that a large part of injected *Esch coli* endotoxin quickly enters the buffy coat Atkins et al (1955) have also found that cortisone 50 mg daily suppresses fever but not leucopenia following the injection of typhoid vaccine, the serum of such rabbits contains as much transferable pyrogenic activity as that of rabbits untreated with cortisone Cortisone thus does not affect the action of pyrogen on blood but its later effect on the fever-producing process

These studies, and particularly those of Grant (1953), suggest that in the rabbit bacterial pyrogen produces in the blood-stream a secondary or endogenous pyrogen with a quicker action, and that plasma is the chief reactor with this bacterial substance

Another approach to the problem of fever in the rabbit has been that of Bennett and Beeson (1953a and b) As has been mentioned, these workers only obtained febrile responses from saline extracts of one normal tissue—namely, polymorphonuclear leucocytes The active material is thermolabile and non-dialysable, it produces no leucopenia or leucocytosis and exhibits no tolerance or cross-tolerance They suggest that this constituent of normal leucocytes may be the intermediate agent between bacterial infection and fever

However, some peculiar facts have not so far been fully explained

(1) The most convenient way of obtaining leucocytes is to inject physiological saline solution into the peritoneal cavity Both the leucocytes and the fluid in which they are suspended are pyrogenic yet the rabbits whence they are drawn have no fever As, in such *animals, the thoracic-duct lymph* and circulating blood contain no demonstrable pyrogenic activity (Bennett 1956b), it is concluded that the pyrogenic substance is not absorbed from the peritoneum

(2) Rabbits in which circulating granulocytes have been abolished by previous treatment with nitrogen mustard respond in the usual way with fever to injections of bacterial pyrogen, influenza virus, and various particulate materials In addition sterile peritoneal exudates produced by injection of physiological saline are pyrogenic even though they contain no leucocytes (Bennett and Beeson 1953b) It therefore seems that there may be a source other than leucocytes for pyrogenic substances, though Bennett (1956a) failed to find it by extracting tissues of leucopenic animals

(3) Injection of pneumococci into the peritoneal cavity produces high fever, yet intravenous or intraperitoneal injection of dead pneumococci produces none Like the sterile exudate, the peritoneal fluid induced by live pneumococci yields

continued with intervals of complete inertia, and the patient was finally delivered spontaneously of a macerated fœtus 110 hours after the membranes had been ruptured No gross abnormality was found *in the fœtus*

The 4 stillbirths in this series illustrate only too clearly one of the dangers of artificial rupture of the membranes as a method of induction of labour Labour failed to start for many hours or days, and then only with irregular and ineffective contractions During all this time the fœtus, perhaps already near the limit of its placental reserve, was subjected to an added measure of anoxia over a long period by the uterine retraction which followed the escape of the liquor amnii It is impossible to know what degree of anoxia was present before the interference was undertaken, or what degree of anoxia was due to the induction It seems likely, however, that it is just in those cases where oxygenation of the fœtal blood is becoming dangerously low that the risk of death from the added anoxia of the induction is so much the greater

If one can be wise after the event, it may be said that, in these four fatal cases, cæsarean section ought to have been done before the fœtus died when the course of labour proved to be so slow In this series of 68 inductions cæsarean section was done on 4 occasions for this very reason The difficulty is always to know in which case, and exactly when, to do this If caution were not exercised, it might be found, too often, that cæsarean section was done for failed induction rather than induction of labour for postmaturity

To say that 4 stillbirths in 68 surgical inductions of labour represents a fœtal mortality of nearly 6% may or may not be significant in the statistical sense of the word, but the figures certainly do not provide any basis for advocating the routine use of artificial rupture of the membranes in an attempt to avoid the dangers of postmaturity They ought, at least, to remind us that surgical induction of labour is not invariably successful, nor is it always safe for the fœtus

Attempts to induce labour with castor oil and enemata too often fail Although a failed "medical induction" is sometimes regarded as entirely harmless, it is often disappointing The moral effect of failure on the patient and her attendant may not always be without remote repercussions on subsequent events Inertia during labour is closely bound up with demoralisation of the patient or her obstetrician Induction of labour by the oxytocin-drip method has had many strong advocates, but among the patients here reported it was not used often enough to enable conclusions to be drawn

Conclusion

An attempt has been made to estimate the saving of infant life that could be achieved by preventing postmaturity Instead of considering gross fœtal and infant mortality-rates, the estimate of risk due to postmaturity has been based upon the incidence of fœtal and neonatal death from anoxia in circumstances which do not allow of any clear alternative explanation for the fatality On this basis it is possible to estimate the maximum possible loss of life that can be attributed to the postmaturity itself

In all the cases in which pregnancy passes the 41st week the loss directly due to postmaturity is less than 1 2%—possibly considerably less It probably varies from something less than 0 4% between the 41st and 42nd weeks to something less than 4 3% after the 44th week has been passed *In a midwifery practice with about 8500 viable births a perfect method of induction of labour used on 2600 occasions immediately before the 41st week of pregnancy was completed could not save more than 14 infant lives* Used on 115 occasions immediately before the 44th week was completed it could not save more than 2 infant lives

An appreciation of these figures is important before we are justified in advocating the routine avoidance of postmaturity by induction of labour with an imperfect method There is reason to believe that, in postmaturity, artificial rupture of the membranes carries with it dangers to the fœtus that are considerably greater than those which the interference is designed to circumvent The statistical studies that have come from Professor Baird's department in Aberdeen, and in particular the observations of Walker and Turnbull (1953) on fœtal blood oxygen content, have focused the attention of all practising obstetricians on the dangers of postmaturity

We must accept that postmaturity carries an increased risk to the fœtus, but this is not necessarily a good reason for forcing the fœtus out of frying-pan of postmaturity into the fire of induction of labour For those who think they have found a safe and effective method of induction there is not any problem For those who are impressed by the fallibility and the dangers of all the present-known methods of induction the management of postmaturity will remain a difficult problem Appreciation of the dangers of postmaturity is essential, but that must not overshadow an understanding of the dangers of induction

In the presence of other complicating factors the management of postmaturity calls for the fullest individual consideration, for all the niceties of judgment, and often also for finesse in treatment In uncomplicated cases, with our present imperfect methods of induction of labour, it is probably better to avoid the treatment of postmaturity altogether rather than to embark on a rigid policy of prevention

I wish to thank my colleagues at Queen Charlotte's Hospital for allowing me to make use of the clinical records of their cases

PHYSICIAN, SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH

> "We are therefore within sight of a rational concept of emphysema reasonably secure in its physiological support, but somewhat tentative in the links between structural and functional change" Arnott *(1956)*

This paper is written with the object of trying to strengthen these links

* * *

Chevalier Jackson (1930) gives a very clear account of bronchial obstruction in all its variations and the several effects that these produce He classifies obstructions into

1 *Complete blockage (corking), which leads to collapse of the* lung beyond the block as the trapped air is absorbed

2 Partial blockage, which simply causes wheezing as the air passes through the constriction

3 *Ball-valve obstruction,* which blocks inspiration but allows air to pass out during expiration This leads to collapse and atelectasis even more quickly than "corking

4 *Check-valve obstruction,* which allows air to be drawn in during inspiration but prevents it from passing out during expiration This leads to distension or emphysema of the lung beyond the valve

An obstruction situated on the junction of two bronchi may act as a ball valve in one and a check valve in the ther, and so give rise to atelectasis and emphysema in wo adjacent segments of lung Jackson's paper is based on observations with a bronchoscope He saw these effects produced by obstructions of several kinds foreign bodies, of which peanuts formed the majority, tumours, both benign and malignant, local swelling of the mucous membrane, and plugs of viscid mucus I am here primarily concerned with the check valve, but the other types of bronchial obstruction and their effects should not be forgotten

* * *

The simplest and most dramatic results of check-valve action are seen in the so-called balloon cysts, which may fill half the thoracic cavity and resemble tension pneumothorax None of those who describe them question their method of production On no other basis can one explain how they quickly fill up again with air under considerable positive pressure after aspiration, and at necropsy it has sometimes been possible to demonstrate their communication with a tiny bronchus (Koontz 1925, Miller 1926, Pearson 1930, Parmelee and Apfelbach 1931; Anspach and Wolman 1933, Miller 1933, Sellors 1938, Kaltreider and Fray 1939, Brown and Brock 1942) There can be no doubt, therefore, that check-valve action is a very potent mechanism in inflating terminal air sacs beyond their natural size Smaller cysts, single or in groups, may result from the same mechanism in a variety of other pathological states Examples are recorded under a number of different names—air cysts, caverns, blebs, bullæ, and focal emphysema—and as being associated with tuberculosis, pneumoconiosis, and staphylococcal pneumonia Asthma is often present as well

From whatever cause they arise and whatever the size or distribution of the cavities, the physiological effects as judged by analyses of blood and air are the same in all and similar to those found in "obstructive" pulmonary emphysema (Christie 1934, Hundato and Fray 1934, Kaltreider and Fray 1939) The air pressure within these cysts has sometimes been recorded In Brown and Brock's case it was -2 ± 2 cm H_2O and remained unaltered by the aspiration of several hundred ml of air In Kaltreider and Fray's case it was -6 ± 5 cm H_2O and the size of the cavity and the pressure were unchanged by aspirating two litres of air In Pearson's case the pressure was very much higher $+4-16$ cm in the cavity, while the initial pleural pressure found when inducing artificial pneumothorax was $-12-3$ cm Similar wide variations of pressure are found in spontaneous pneumothorax

It is only the unfortunate few that pump themselves up to desperately high levels In either condition a state of equilibrium, depending on the precise anatomy of the valve, is reached in every case If it closes completely as soon as the inspiratory effort ceases, the minimum pressure within the cavity will be about atmospheric, and the maximum reading will represent a balance between the expiratory pulmonary pressure on the retained air and the elastic tension of the surrounding lung The high positive readings reached by Pearson (1930) or found in tension pneumothorax could never be reached by the mere retention of air drawn in by inspiratory effort. If, however, the valve did not close completely during expiration, and the pressure in the larger cartilaginous air tubes was forced up by a cough against the resistance of a closed glottis, air could be forced into the cavity as in pumping up a tyre I think that it is in this way that the high positive pressures are produced The ingenious researches of Dayman (1951) threw considerable light on the many factors involved and led him to conclude that even in health the intrathoracic airways can behave as check valves to a slight degree during expiration, though the effect is very much greater in advanced emphysema when the elasticity of the lungs is impaired

The clinical course taken by these cavities is as varied as are the diseases that give rise to them and the nature and varying patency of their communication with the bronchi If the airway is cleared the cyst will collapse and disappear completely If check valve changes to ball valve or "corking," the cavity will be replaced by atelectasis With continued check-valve action the cyst may enlarge or remain stationary and clinically silent It may fill with clear mucus or infection may turn it into an abscess, which in turn may discharge and heal, resolve to form a fibrous scar, or persist as bronchiectasis These possibilities apply equally whether the cyst be large or minute

No great exception will probably be taken to what has been said so far, but it may not be so readily accepted that generalised hypertrophic emphysema is no more than the distension of every terminal air-sac into a tiny tension cyst by check-valve action, and that the disease-state that causes it is asthma Still less is it accepted that the presence of generalised emphysema is proof of a primary asthmatic state, though no other explanation has ever been put forward The reason for this reluctance is twofold, and as in so many controversies it arises mainly from limitations of nomenclature Asthma is a term reserved exclusively for the classical paroxysmal type Emphysema is a name given equally to a clinical picture and a pathological state, yet if we find the former it is by no means proof that the latter is also present

Although we limit the meaning of the term asthma in this way, the disorder can, in fact, range through every grade of severity from the classical paroxysmal attack to a disturbance so slight and chronic that it is often regarded as lying within the limits of normal health (Lister 1955) This slight and chronic form of asthma, for which we have no generally accepted name and which is very much more common than the paroxysmal, is also the form particularly prone to produce emphysema This view of the matter is of respectable antiquity, and was put forward very clearly by Laennec (1829), though he also was cramped, as we are, by having no generally accepted name for the minor grade He called it the "dry catarrh", and I cannot do better than quote from him at some length He says

> "This disease, when existing in a middling degree, frequently remains altogether latent for a long course of years, the subjects of it being no further conscious of its presence than observing that they are shorter of breath than others when they ascend an elevation or attempt to run After a time the dyspnœa comes on in fits which last usually several days and are so severe as to merit and obtain the name of asthma" Again, "The most common cause of dyspnœa when of sufficient severity to be termed asthma is a dry catarrh latent or manifest and emphysema of the lungs is the consequence of this" Again, "Pulmonary emphysema supervenes almost always to an extensive and severe dry catarrh, and nearly all the subjects of asthma from the last named disease, on examination after death, exhibit a greater or less dilatation of some of the bronchial cells These facts lead us to a simple explanation of the mechanism of dilatation of the air cells It has been already shown that in the dry catarrh, the smaller bronchial tubes are frequently completely obstructed, either by the pearly sputa or by the swelling of their inner membrane. Now, since the muscles of inspiration are numerous and powerful, while expiration, on the other hand, is produced merely by the elasticity of the parts and by the feeble contraction of the intercostal muscles [sic] it must frequently happen that the air, which during inspiration had overcome the resistance opposed to its entrance by the tumid state of the bronchial membrane and the sputa, is unable to force the same obstacles during expiration, and remains therefore imprisoned in the cells, by a mechanism somewhat similar to the valve of an air gun The succeeding inspirations, or at least such of them as are energetic, introduce a fresh supply of air into the same cells, and thereby necessarily occasion their dilatation and, provided the obstruction is of some continuance, the dilated condition of the cells will be rendered permanent. It follows from this view of the matter that the dry catarrh tends as naturally

continued with intervals of complete inertia, and the patient was finally delivered spontaneously of a macerated fœtus 110 hours after the membranes had been ruptured No gross abnormality was found in the fœtus

The 4 stillbirths in this series illustrate only too clearly one of the dangers of artificial rupture of the membranes as a method of induction of labour Labour failed to start for many hours or days, and then only with irregular and ineffective contractions During all this time the fœtus, perhaps already near the limit of its placental reserve, was subjected to an added measure of anoxia over a long period by the uterine retraction which followed the escape of the liquor amnii It is impossible to know what degree of anoxia was present before the interference was undertaken, or what degree of anoxia was due to the induction It seems likely, however, that it is just in those cases where oxygenation of the fœtal blood is becoming dangerously low that the risk of death from the added anoxia of the induction is so much the greater

If one can be wise after the event, it may be said that, in these four fatal cases, cæsarean section ought to have been done before the fœtus died when the course of labour proved to be so slow In this series of 68 inductions cæsarean section was done on 4 occasions for this very reason The difficulty is always to know in which case, and exactly when, to do this If caution were not exercised, it might be found, too often, that cæsarean section was done for failed induction rather than induction of labour for postmaturity

To say that 4 stillbirths in 68 surgical inductions of labour represents a fœtal mortality of nearly 6% may or may not be significant in the statistical sense of the word, but the figures certainly do not provide any basis for advocating the routine use of artificial rupture of the membranes in an attempt to avoid the dangers of postmaturity They ought, at least, to remind us that surgical induction of labour is not invariably successful, nor is it always safe for the fœtus

Attempts to induce labour with castor oil and enemata too often fail Although a failed "medical induction" is sometimes regarded as entirely harmless, it is often disappointing The moral effect of failure on the patient and her attendant may not always be without remote repercussions on subsequent events Inertia during labour is closely bound up with demoralisation of the patient or her obstetrician Induction of labour by the oxytocin-drip method has had many strong advocates, but among the patients here reported it was not used often enough to enable conclusions to be drawn

Conclusion

An attempt has been made to estimate the saving of infant life that could be achieved by preventing postmaturity Instead of considering gross fœtal and infant mortality-rates, the estimate of risk due to postmaturity has been based upon the incidence of fœtal and neonatal death from anoxia in circumstances which do not allow of any clear alternative explanation for the fatality On this basis it is possible to estimate the maximum possible loss of life that can be attributed to the postmaturity itself

In all the cases in which pregnancy passes the 41st week the loss directly due to postmaturity is less than 1 2%—possibly considerably less It probably varies from something less than 0 4% between the 41st and 42nd weeks to something less than 4 3% after the 44th week has been passed In a midwifery practice with about 8500 viable births a perfect method of induction of labour used on 2600 occasions immediately before the 41st week of pregnancy was completed could not save more than 14 infant lives Used on 115 occasions immediately before the 44th week was completed it could not save more than 2 infant lives

An appreciation of these figures is important before we are justified in advocating the routine avoidance of postmaturity by induction of labour with an imperfect method There is reason to believe that, in postmaturity, artificial rupture of the membranes carries with it dangers to the fœtus that are considerably greater than those which the interference is designed to circumvent The statistical studies that have come from Professor Baird's department in Aberdeen, and in particular the observations of Walker and Turnbull (1953) on fœtal blood oxygen content, have focused the attention of all practising obstetricians on the dangers of postmaturity

We must accept that postmaturity carries an increased risk to the fœtus, but this is not necessarily a good reason for forcing the fœtus out of frying-pan of postmaturity into the fire of induction of labour For those who think they have found a safe and effective method of induction there is not any problem For those who are impressed by the fallibility and the dangers of all the present-known methods of induction the management of postmaturity will remain a difficult problem Appreciation of the dangers of postmaturity is essential, but that must not overshadow an understanding of the dangers of induction

In the presence of other complicating factors the management of postmaturity calls for the fullest individual consideration, for all the niceties of judgment, and often also for finesse in treatment In uncomplicated cases, with our present imperfect methods of induction of labour, it is probably better to avoid the treatment of postmaturity altogether rather than to embark on a rigid policy of prevention

I wish to thank my colleagues at Queen Charlotte's Hospital for allowing me to make use of the clinical records of their cases

PHYSICIAN, SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH

"*We are therefore within sight of a rational concept of emphysema reasonably secure in its physiological support, but somewhat tentative in the links between structural and functional change*" Arnott (1956)

This paper is written with the object of trying to strengthen these links

* * *

Chevalier Jackson (1930) gives a very clear account of bronchial obstruction in all its variations and the several effects that these produce He classifies obstructions into

1 *Complete blockage (corking), which leads to collapse* of the lung beyond the block as the trapped air is absorbed

2 Partial blockage, which simply causes wheezing as the air passes through the constriction

3 Ball-valve obstruction, which blocks inspiration but allows air to pass out during expiration This leads to collapse and atelectasis even more quickly than "corking"

4 *Check-valve obstruction*, which allows air to be drawn in during inspiration but prevents it from passing out during expiration This leads to distension or emphysema of the lung beyond the valve

while check-valve action remarkably prevents anything approaching a normal range of expiration He cannot empty his chest further because the air is trapped in the alveoli But if his bronchioles could maintain a normal calibre during expiration he would be able to empty his chest, and there is no reason, so far as this figure indicates, why his lungs should not then return completely to normal just as the local emphysema in one of Jackson's patients would after he had extracted the peanut Gough (1955) has shown that in the lungs of fatal cases of status asthmaticus there is no structural emphysema at necropsy, though one can be sure that if films had been taken of these patients shortly before death they would have revealed an even greater degree of distension than fig 2 Functional emphysema then is a completely reversible state entirely comparable to transient tension cysts, which vanish when the airway is reopened The more brief and infrequent the asthmatic attacks, the less likely are permanent structural changes to supervene, and vice versa

* * *

To produce structural emphysema, some additional factor is required to damage the tense alveolar meshwork In Flavell's (1952) opinion healthy alveoli cannot be ruptured by any physiological range of pressure Moolton (1935) showed that, if the alveolar meshwork had been damaged, pressures well within the physiological range could produce cavities which would not return completely to their original size when the pressure was relieved Gough also points out that emphysema is not found at necropsy in pure spasmodic status asthmaticus, but if chronic bronchitis (by which he presumably means infection) has been present as well, then structural emphysema is found post mortem Given time several factors can, alone or in combination, produce this damaging effect and, as it were, fix the terminal air-sacs in their distended condition As age advances, the skeleton becomes more rigid and the posture of habitual elevation of the ribs and bowed back becomes less and less easy to correct Adami and Nicholls thought that the capillaries might be compressed and so the blood-supply to the tense walls of the alveoli would be impaired This may be true Certain it is that as we grow older bodily structures tend to lose elasticity, and people vary greatly in the age at which these changes begin and in the organs most affected We know they can arise in the lungs and cause the so-called small-lunged or atrophic emphysema If a lung undergoing this degenerative process has been subject for several years to the check-valve action of chronic asthma or "dry catarrh", the classical picture of hypertrophic emphysema will be produced in its structural sense The lungs are bulky, pale, and dry, and have the feel of a feather pillow Microscopically the terminal air-sacs are seen to be distended, with thin, atrophic walls, many of which have ruptured so that adjacent alveoli coalesce Heavy smoking and living in polluted air, or the inhalation of noxious dusts, bring the risk of chemical and mechanical damage

Infection, however, is by far the most common and important damaging factor It so often dominates the clinical picture and compels the patient to seek our advice that we tend to regard it as the primary cause of the emphysema Infection also commonly dominates the pathological picture, as indeed it must, whenever it is present, seeing that purely functional emphysema leaves no post-mortem change But non-specific infection alone cannot produce generalised emphysema It is true that histologically in acute bronchopneumonia one can find areas in which their walls have ruptured and the alveoli have become confluent, and no doubt the same mechanisms have been at work to produce these changes as in more chronic illnesses It is also true, as already stated, that conditions of long standing—for instance, tuberculosis and pneumoconiosis—can produce tension cysts and areas of focal emphysema, but in these diseases the changes will be relatively gross and uneven in distribution Other parts of the lung will be collapsed from complete bronchial obstruction or consolidated or fibrotic from the primary pathological process By contrast the dilatation of and damage to the alveoli and bronchioles in "chronic bronchitis and emphysema" is spread relatively evenly throughout the whole of the lung parenchyma

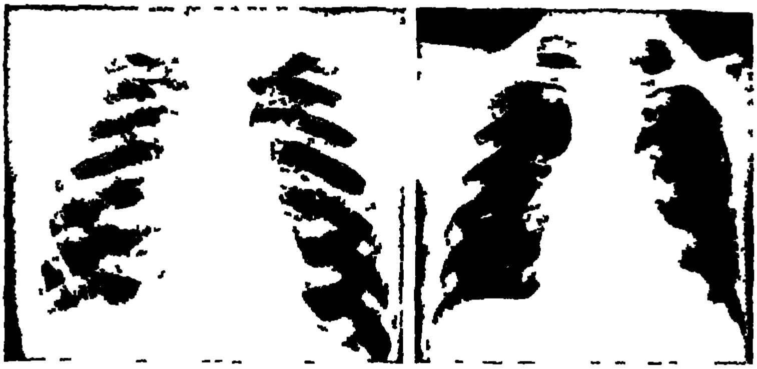
There are other reasons for suggesting that this disease is not primarily the result of infection The pathological picture is well described and illustrated by Reid (1954) She points out that the earliest change consists in an extension beyond the normal number and range of distribution of goblet cells and simple catarrh of the bronchial mucosa This entirely conforms to the natural history of the disease as observed clinically The more carefully we conduct our history-taking and examination, the more will we find evidence of a long-standing, constitutional, hereditary, or allergic state corresponding to Laennec's "dry catarrh" Other members of the family may have been asthmatic or bronchial There may be a history of hay-fever or frequent colds that start in the nose and later settle on the chest, or of winter and morning cough often attributed to smoking, all preceding the first recognisable onset of infection Many patients will distinguish between attacks of wheezing with thick, mucoid sputum, which they term asthma, and those with looser, yellow sputum, often associated with fever, which they term bronchitis

Precisely as one can trace in one's practice an unbroken range of cases through every grade of severity, from the mildest examples of dry catarrh to those in whom the entire respiratory tract is heavily and permanently infected, so one can observe in them the corresponding grade of emphysema from the reversible or functional to the permanent or structural The pathological picture also conforms As the catarrh and mucus secretion increases so will the mechanical effects of the bronchial obstruction increase These will not only be check valves There will also be partial blocks, corkings, and ball valves, to use Jackson's terms, all according to the precise site and degree of secretion and congestion at the moment, each producing its appropriate effect of emphysema, rhonchi, or atelectasis To these will be added the secondary effects of the inflammatory process, in the form of minute patches of pneumonia, and small abscesses, all in various stages of activity and resolution, which make up the full-blown picture described by Reid

* * *

Why does bronchitis become chronic in only an unfortunate minority ? Why do not all who dwell or work in polluted atmospheres develop emphysema ? And why do we find atrophic, small lungs in some and hypertrophic emphysema in others ? The reason must surely be that the lungs that develop emphysema are different They have reacted in a different way—in

to the production of emphysema of the lungs as the chronic mucous catarrh leads to dilatation of the bronchis ”



a b
Fig 1—Chest of normal man (a) inspiration, (b) expiration

This check-valve theory, as it may be termed, seems to have attracted little attention or support It was soon supplanted by the expiratory theory put forward in the first place by Mendelssohn (1845) and subsequently elaborated in the forceful writings of Jenner (1865) They believed that emphysema was caused by strong expiratory effort against resistance as in the expulsive effort of childbirth, glass-blowing, the playing of wind instruments, and particularly the constant coughing of sufferers from chronic bronchitis The theory was that during forced expiration the rigid portions of the thoracic cage—namely, the ribs—pressed on the underlying lung and forced air under pressure into those parts which were surrounded only by soft tissues, particularly around the apices and in the costophrenic angles The presence of universal emphysema was explained by the hypothesis that as the ribs moved up and down with respiration they forced the air from immediately beneath them into those portions of the lungs underlying the intercostal spaces The theory is easily illustrated by grasping a slightly inflated rubber balloon The fingers represent the ribs and the bubbles of rubber extruded between them represent the emphysema One may not think this a particularly convincing theory to have held the field for so long, but it still survives, if not quite in this form, in textbooks, and by implication in the commonplace diagnosis “ chronic bronchitis and emphysema ” Recently there appear to be signs of a return to Laennec’s theory

At the International Congress of Internal Medicine at Madrid last autumn Arnott (1956) referred to it and made the statement quoted at the beginning of this paper Previously Brodie and Dixon (1903) had been led by their pharmacological experiments to the conclusion that the asthmatic state was due to check-valve action from spasm of the bronchioles, which could be induced by vagus stimulation or drugs (pilocarpine) Adami and Nicholls (1910) refer to their work, and put forward the check-valve action of asthma as a satisfying explanation for the production of emphysema Norris and Landis (1924) mention the theory, but with no special emphasis, among several others current at that time heredity, occupation, chronic bronchitis, and premature ossification of costal cartilages

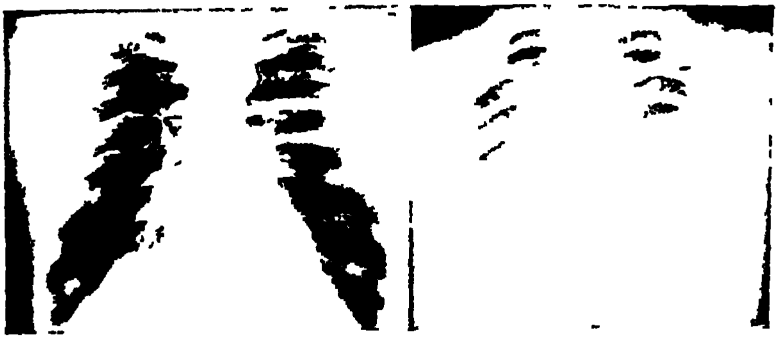
* * *

When one considers how many diseases can cause check-valve action, their ever-changing pattern, and the complications that may arise, one can well appreciate the difficulties of those who have sought to define and pin down a diagnosis of emphysema and to assess its severity by some clinical, radiological, or physiological formula based on a single examination

For instance, Fletcher (1952) compared the clinical opinion of eight physicians against a radiological diagnosis of emphysema The patients all had pneumoconiosis Knott and Christie (1952) found wide discrepancy between clinical and radiological diagnosis Donald (1953) made physiological tests on patients diagnosed as emphysematous on clinical and radiological grounds and found that there were too many variables (in sepsis, bronchospasm, and cardiac efficiency) to allow of close comparison Curtis (1955) made physiological tests on patients before thoracotomy and compared his findings with the presence or absence of emphysema in biopsy specimens In almost all his patients the operation was pneumonectomy for pulmonary tuberculosis Yet these papers formed the subject of a leading article (*Lancet* 1956) headed “ Hypertrophic Emphysema ”

Confusion will arise if we regard emphysema as a primary disease and one merely found in frequent association with other chest complaints, as so much of the literature on the subject seems to imply It is always secondary, and the result of check-valve action The number, size, and distribution of the distended air sacs depend on the primary pathological process producing the check valve, and may in fact constitute a valuable clue to its nature Thus, just as a balloon cyst or lobar emphysema (Cottom and Myers 1957) in a child suggests an abnormal bronchiole, or a group of tension cysts or area of focal emphysema may suggest tuberculosis, so universal distension indicates a condition that produces check-valve action uniformly throughout the lungs, and it is hard to think of an alternative to asthma that could do this

Again, to borrow Arnott’s terminology, emphysema may be functional or structural So far as it is functional it is potentially reversible, and it certainly will fluctuate widely in degree from time to time Figs 1 and 2 illustrate emphysema of this kind Fig 1 shows the chest of a healthy man aged 60 in maximum inspiration and expiration Fig 2 shows the corresponding films of a man complaining of increasing breathlessness on effort, typical of Laennec’s “ dry catarrh ” Here the diaphragm is depressed and flattened to a degree well below that which the most forcible normal inspiration can produce,



a b
Fig 2—Chest of man with emphysema (a) inspiration, (b) expiration

while check-valve action remarkably prevents anything approaching a normal range of expiration. He cannot empty his chest further because the air is trapped in the alveoli. But if his bronchioles could maintain a normal calibre during expiration he would be able to empty his chest, and there is no reason, so far as this figure indicates, why his lungs should not then return completely to normal just as the local emphysema in one of Jackson's patients would after he had extracted the peanut. Gough (1955) has shown that in the lungs of fatal cases of status asthmaticus there is no structural emphysema at necropsy, though one can be sure that if films had been taken of these patients shortly before death they would have revealed an even greater degree of distension than fig. 2. Functional emphysema then is a completely reversible state entirely comparable to transient tension cysts, which vanish when the airway is reopened. The more brief and infrequent the asthmatic attacks, the less likely are permanent structural changes to supervene, and vice versa.

* * *

To produce structural emphysema, some additional factor is required to damage the tense alveolar meshwork. In Flavell's (1952) opinion healthy alveoli cannot be ruptured by any physiological range of pressure. Moolton (1935) showed that, if the alveolar meshwork had been damaged, pressures well within the physiological range could produce cavities which would not return completely to their original size when the pressure was relieved. Gough also points out that emphysema is not found at necropsy in pure spasmodic status asthmaticus, but if chronic bronchitis (by which he presumably means infection) has been present as well, then structural emphysema is found post mortem. Given time several factors can, alone or in combination, produce this damaging effect and, as it were, fix the terminal air-sacs in their distended condition. As age advances, the skeleton becomes more rigid and the posture of habitual elevation of the ribs and bowed back becomes less and less easy to correct. Adami and Nicholls thought that the capillaries might be compressed and so the blood-supply to the tense walls of the alveoli would be impaired. This may be true. Certain it is that as we grow older bodily structures tend to lose elasticity, and people vary greatly in the age at which these changes begin and in the organs most affected. We know they can arise in the lungs and cause the so-called small-lunged or atrophic emphysema. If a lung undergoing this degenerative process has been subject for several years to the check-valve action of chronic asthma or "dry catarrh", the classical picture of hypertrophic emphysema will be produced in its structural sense. The lungs are bulky, pale, and dry, and have the feel of a feather pillow. Microscopically the terminal air-sacs are seen to be distended, with thin, atrophic walls, many of which have ruptured so that adjacent alveoli coalesce. Heavy smoking and living in polluted air, or the inhalation of noxious dusts, bring the risk of chemical and mechanical damage.

Infection, however, is by far the most common and important damaging factor. It so often dominates the clinical picture and compels the patient to seek our advice that we tend to regard it as the primary cause of the emphysema. Infection also commonly dominates the pathological picture, as indeed it must, whenever it is present, seeing that purely functional emphysema leaves no post-mortem change. But non-specific infection alone cannot produce generalised emphysema. It is true that histologically in acute bronchopneumonia one can find areas in which their walls have ruptured and the alveoli have become confluent, and no doubt the same mechanisms have been at work to produce these changes as in more chronic illnesses. It is also true, as already stated, that conditions of long standing—for instance, tuberculosis and pneumoconiosis—can produce tension cysts and areas of focal emphysema, but in these diseases the changes will be relatively gross and uneven in distribution. Other parts of the lung will be collapsed from complete bronchial obstruction or consolidated or fibrotic from the primary pathological process. By contrast the dilatation of and damage to the alveoli and bronchioles in "chronic bronchitis and emphysema" is spread relatively evenly throughout the whole of the lung parenchyma.

There are other reasons for suggesting that this disease is not primarily the result of infection. The pathological picture is well described and illustrated by Reid (1954). She points out that the earliest change consists in an extension beyond the normal number and range of distribution of goblet cells and simple catarrh of the bronchial mucosa. This entirely conforms to the natural history of the disease as observed clinically. The more carefully we conduct our history-taking and examination, the more will we find evidence of a long-standing, constitutional, hereditary, or allergic state corresponding to Laennec's "dry catarrh". Other members of the family may have been asthmatic or bronchial. There may be a history of hay-fever or frequent colds that start in the nose and later settle on the chest, or of winter and morning cough often attributed to smoking, all preceding the first recognisable onset of infection. Many patients will distinguish between attacks of wheezing with thick, mucoid sputum, which they term asthma, and those with looser, yellow sputum, often associated with fever, which they term bronchitis.

Precisely as one can trace in one's practice an unbroken range of cases through every grade of severity, from the mildest examples of dry catarrh to those in whom the entire respiratory tract is heavily and permanently infected, so one can observe in them the corresponding grade of emphysema from the reversible or functional to the permanent or structural. The pathological picture also conforms. As the catarrh and mucus secretion increases so will the mechanical effects of the bronchial obstruction increase. These will not only be check valves. There will also be partial blocks, corkings, and ball valves, to use Jackson's terms, all according to the precise site and degree of secretion and congestion at the moment, each producing its appropriate effect of emphysema, rhonchi, or atelectasis. To these will be added the secondary effects of the inflammatory process, in the form of minute patches of pneumonia, and small abscesses, all in various stages of activity and resolution, which make up the full-blown picture described by Reid.

* * *

Why does bronchitis become chronic in only an unfortunate minority? Why do not all who dwell or work in polluted atmospheres develop emphysema? And why do we find atrophic, small lungs in some and hypertrophic emphysema in others? The reason must surely be that the lungs that develop emphysema are different. They have reacted in a different way—in a word they are “ allergic ” (for that is all that this term means) and subject in some degree to the chronic, dry catarrh of Laennec and the check-valve action that this state applies

The lungs of these people present a constantly shifting pattern depending on fluctuations in the asthmatic state, variations in degree of infection, and the process of ageing Occupation, environment, and the efficiency of the cardiovascular system all have an additional and indirect bearing Thus at any given moment the degree of emphysema demonstrable by radiography or at the bedside will be in part functional or reversible because of check-valve action, and in part structural or irreversible from breakdown of the alveolar meshwork

One may make a more or less shrewd estimate of the relative proportions of these two elements (the functional and the structural) from the history and clinical picture In an elderly patient with rigid chest, inelastic skin, and hardened arteries, who has suffered for years from attacks of “ bronchitis ” with purulent sputum or has lived and worked in a polluted atmosphere, one would naturally expect the condition to be largely irreversible, the results of treatment meagre and the prognosis correspondingly poor In younger subjects with a more spasmodic history, little or no infection, and otherwise good general health and environment, the functional element might be expected to predominate On such a view one can readily understand—indeed one would expect—the poor results obtained with ephedrine and aminophylline in emphysema (Whitfield et al 1950, 1951) No drug could alter a condition due entirely to structural damage The observations were made when no bronchospasm was present Clinical details of the patients were not given, but the authors say that they were not clinically asthmatic and that there was nothing to suggest that asthma had been the cause of their ventilatory insufficiency Laennec might, however, have regarded them as subject to “ dry catarrh ”

Summary

Emphysema is never a primary disease, but always secondary

It is a state of over-distension of the terminal air-sacs of the lungs by check-valve action in the small bronchi or bronchioles A variety of conditions can cause this

Tension cysts or focal emphysema arise from the partial obstruction of one or a few bronchioles

Generalised emphysema results *only from asthma*—particularly from its minor and chronic form, rather than from the classical paroxysmal type

Functional emphysema is the distension of healthy alveoli by check-valve action It can be completely relieved by the removal of the obstruction

Structural emphysema is the irreversible state resulting from damage to the over-distended alveolar meshwork by secondary factors

EFFECTS OF PENICILLAMINE AND DIMERCAPROL ON TURNOVER OF COPPER IN PATIENTS WITH WILSON'S DISEASE

S B OSBORN
B Sc Lond, A Inst P
PRINCIPAL PHYSICIST, UNIVERSITY COLLEGE HOSPITAL, LONDON W C 1

J M WALSHE
M A, M B Cantab, M R C P
ASSISTANT, MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON, W C 1

IT is now established that in patients with Wilson's disease (hepatolenticular degeneration) there is an inability to synthesise the copper-binding serum-protein cæruloplasmin, and copper therefore accumulates in the body, chiefly in the brain and liver Associated with these phenomena are an increased excretion of copper in the urine and a low level of copper in the plasma Moreover 60–80% of the serum-copper is “ direct reacting”—i e, not bound to cæruloplasmin—in contrast to healthy people, in whom only about 10% of the copper is not protein-bound The evidence for these observations has been reviewed by one of us (Walshe 1957)

Studies with radioactive copper (^{64}Cu) (Earl et al 1954, Bearn and Kunkel 1955, Bush et al 1955) have shown that, in healthy people, the copper is rapidly removed from the plasma, to reappear about twelve hours later bound to cæruloplasmin In patients with hepatolenticular degeneration this rapid fall and secondary rise do not take place, the ^{64}Cu level falling slowly but steadily during the period of study The patients with Wilson's disease excreted a higher percentage of ^{64}Cu in the urine and far less in the stools than did the healthy people

Hitherto the most effective treatment for patients with Wilson's disease has been to remove copper from the body with repeated courses of intramuscular dimercaprol (Denny-Brown and Porter 1951) In cases which are not resistant to this treatment and in patients who do not become sensitive to dimercaprol significant improvement may take place (Bearn 1956) Penicillamine hydrochloride by mouth in doses up to 1 5 g daily may be more effective than dimercaprol in promoting cupruresis (Walshe 1956, Bearn 1957)

In the present study the efficacy of dimercaprol and penicillamine in increasing the excretion of intravenously injected ^{64}Cu were compared The number of experiments

was limited to a minimum to avoid giving unnecessary doses of a radioactive material to adolescents The opportunity was taken to make surface counts over the body to try and determine the site of concentration of the isotope after injection

Methods

The studies were made on one healthy male, aged 22, and on three patients with Wilson's disease Two of these have been reported previously (Walshe 1956, cases 3 and 5), and the third was a boy aged 18, who had the typical disease with a history of three years' tremor and slurred speech All three patients had difficulty in providing urine to a strict time schedule, but only two specimens were lost during the experiments (see figures)

The chemical method of estimating copper was that described by Earl (1954) and modified for greater accuracy by Walshe (1956)

Since inorganic salts of copper are toxic, it was important that the mass of copper used should be as small as possible A method was developed by Payne et al (1957) at the A E R E, Harwell, for producing copper of very high specific activity which at the time of injection had a mass of 1–3 μg of Cu for an activity of 100 μC The urine was assayed for radioactivity by counting samples dried in planchettes, as described by Anderson et al (1956), with a G E C type EHM 2 end-window Geiger-Müller tube The tube was standardised by counting a planchette containing a known fraction of the original ^{64}Cu

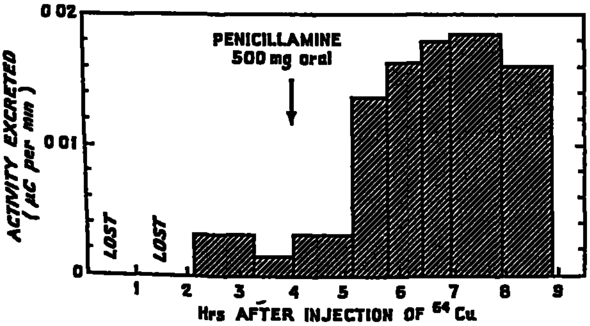

Fig 1—Excretion of ^{64}Cu by case 1 First two specimens of urine were lost.

For external counting of the liver a sensitive scintillation counter with a thallium-activated sodium-iodide crystal was used This was adjusted against constant skin markings by the technique of Riddell et al (1957)

Results

In the pilot experiment made on case 1 after the injection of ^{64}Cu, the first specimen of urine was lost, but by four hours the rate of excretion was 0 0015 μC a minute At this point she was given penicillamine 500 mg by mouth, and thereafter there was a steady increase in activity secreted until at eight hours she was excreting ^{64}Cu at 0 0186 μC a minute, a twelvefold increase (fig 1)

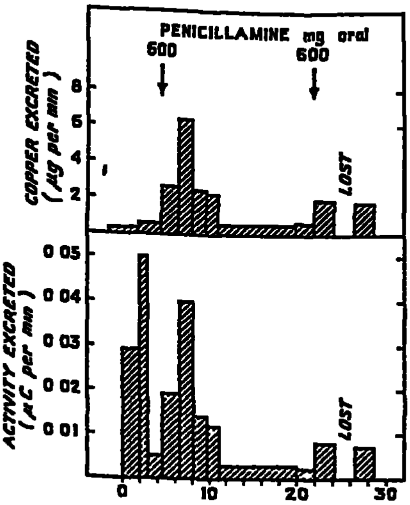

Fig 2—Excretion of copper by case 2. One specimen of urine at about 23 hours was lost

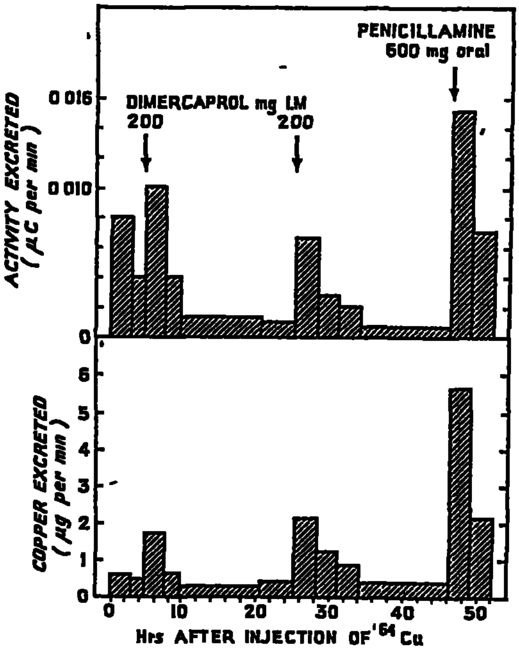

Fig 3—Excretion of copper by case 3

In case 2 the excretion of copper was determined both by radioactive and by chemical methods for twenty-nine hours after the injection of ^{64}Cu 100 μC During this time he was given penicillamine 600 mg by mouth at four hours and again at twenty-two hours As in case 1, the excretion of ^{64}Cu had *diminished to 0 005 μC a minute by four hours* After the first dose of penicillamine it increased to a maximum of 0 04 μC a minute and did not return to the resting value for nearly eight hours During this time 8 52 μc was excreted, if the initial rate had been maintained throughout, the amount would have been 1 92 μC Following the second dose of penicillamine at twenty-two hours there was again an immediate increase in the radioactivity of the urine (fig 2)

The urinary excretion of copper determined by chemical means shows a close correspondence over this twenty-nine hour period, except that the initial high excretion of ^{64}Cu is naturally not reflected by the excretion of non-radioactive copper The increase of excretion due to penicillamine occurs at the same point in the time scale and is of very similar magnitude on each occasion During the eight hours after the first dose of *penicillamine* 1300 μg of copper was excreted, at the base-line rate the excretion would have been 200 μg The

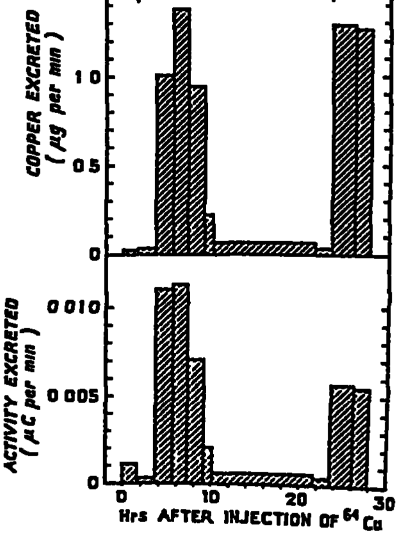

Fig 4—Excretion of copper by healthy man.

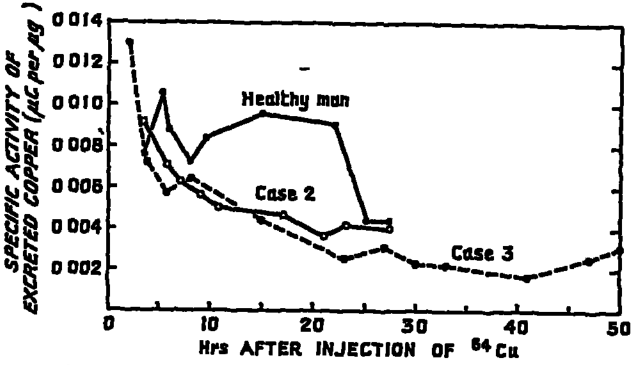

Fig 5—Variations in specific activity of excreted copper

figures available for the second peak also corresponded closely with the results obtained by radioactive assay

Case 3 showed the same immediate considerable excretion of ^{64}Cu as did case 2 Clearly it had not reached a base-line when he was given intramuscular dimercaprol 200 mg at four hours This, however, increased the excretion of ^{64}Cu to a maximum of 0 01 μC a minute, an increase of about four times the calculated base-line The excretion of ^{64}Cu during the period of the cupruresis was 2 5 μC compared with a theoretical excretion of 0 75 μC if dimercaprol had not been given A second injection of dimercaprol at twenty-five hours had an effect almost exactly like that of the first, with a total excretion of 2 13 μC against a calculated 0 58 μC for the period At forty-six hours penicillamine 600 mg was given by mouth This was followed by an increase in excretion of ^{64}Cu from 0 00065 μC a minute to a peak of 0 015 μC a minute—a twenty-fold rise, compared with increases of four and six for dimercaprol

The excretion of copper studied by chemical methods showed a similar picture, with an increase in the cupruresis of five-fold for each of the two injections of dimercaprol and one of fourteen-fold for penicillamine (fig 3)

Finally, a healthy man was studied by a similar experimental procedure He was given two oral doses of penicillamine, each of 600 mg, at four hours and at twenty-four hours The excretion of ^{64}Cu reached a peak of 0 0123 μC a minute after the first dose Calculated from the area of the peak this is a forty-seven-fold increase above the base-line However, after the second dose the peak was only nineteen times the base-line These values compare with increases of 48 and 44 times for copper determined by the chemical method (fig 4)

In cases 2 and 3 with hepatolenticular degeneration the specific activity * of the copper in the urine decreased steadily, whereas in the healthy man it stayed high for about twenty-four hours before decreasing to a value similar to that found in the two patients (fig 5) The significance of this is discussed below

Surface counts were made on case 3 and on the healthy man These showed that, while there was sufficient activity to estimate, the only site of concentration of injected ^{64}Cu was the liver In the healthy man 95% of the injected ^{64}Cu was located in the liver at ten hours, and thereafter there was a steady decline to 70% at fifty hours In case 3 there was never more than 40% of the ^{64}Cu present in the liver, and the variations of liver activity observed after the doses of the sequestrating agents are of very doubtful significance (fig 6)

The results are summarised in the accompanying table

Discussion

The original intention of this work was not to study the differences in copper metabolism between the healthy and patients with Wilson's disease, though this was in fact demonstrated by a comparison of the response of these two groups to penicillamine at four hours and at twenty four hours

In the healthy man there was a forty-seven-fold increase in the excretion of ^{64}Cu at four hours but only twenty-fold at twenty-four hours Presumably by this time much of the ^{64}Cu had become bound to cæruloplasmin and was no longer available for excretion In Wilson's disease, on the other hand, the response to penicillamine did not show this decrease (case 2, thirteen-fold at four hours, case 3, twenty-one-fold at forty-six hours) Presumably since the copper does not become protein-bound it remains freely available for excretion throughout the period of study

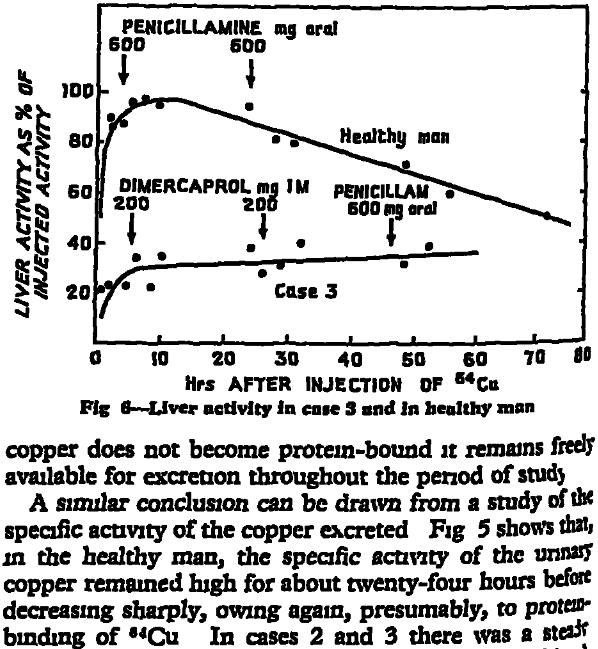

Fig 6—Liver activity in case 3 and in healthy man

A similar conclusion can be drawn from a study of the specific activity of the copper excreted Fig 5 shows that, in the healthy man, the specific activity of the urinary copper remained high for about twenty-four hours before decreasing sharply, owing again, presumably, to protein-binding of ^{64}Cu In cases 2 and 3 there was a steady decline in specific activity as the ^{64}Cu became diluted throughout the body pool The external body-counters also revealed the metabolic abnormality in the patient studied In the healthy control more than 90% of the injected copper was concentrated in the liver at ten hours, but in the patient only 40% of the copper was so concentrated

It might at first appear surprising that the healthy man had a greater percentage increase in copper excretion after penicillamine than had any of the patients, but it must be remembered that the resting excretion was extremely small, and the peak excretion never approached the very high values observed in Wilson's disease

---

* The specific activity is calculated by dividing the activity of copper excreted in μC a minute by the quantity in μg a minute It has nothing to do with absolute quantities of metal

Person	Excretion of copper (μg a minute)					Excretion of ^{64}Cu (μC a minute)					
	Resting	After penicillamine	Times greater*	After dimercaprol	Times greater*	Resting	After penicillamine	Times greater*	After dimercaprol	Times greater	Total ^{64}Cu excreted
Healthy man	0 026	1 37	× 48	—	—	0·0002	0·0123	× 47	—	—	5 7 μC in 28 hr
	0 031	1 28	× 44	—	—	0 00028	0 0057	× 19	—	—	
Case 1						0 0015	0·0186	× 12	—	—	4 2 μC in 9 hr
Case 2	0 54	6 36	× 12	—	—	0·003	0·010	× 13			19 μC in 29 hr
Case 3	0 54			1 7	× 3	0·0025			0·010	× 4	11 5 μC in 52 hr
	0 38			2 1	× 5 5	0 0010			0 0066	× 6 6	
	0 30	5 6	× 14	—	—	0 0007	0·015	× 21			

* The increase is calculated from the area of the peak, not from the height

One other point very clearly shown by these experiments is that penicillamine is a very powerful agent for the mobilisation of body-copper, and that the increased copper which appears in the urine is released from body stores and has not been carried through from the gut There is also support for the view that penicillamine is more active than dimercaprol in this respect

Summary

The excretion of an injected dose of 100 μC of ^{64}Cu was studied in one healthy man and three patients with Wilson's disease together with the effect of oral penicillamine and intramuscular dimercaprol

The results show clearly that penicillamine is very active in promoting the excretion of copper and appears to be superior to dimercaprol in this respect There is good correspondence between the chemical and radioactive determinations of urinary copper

The bulk of the injected copper was concentrated in the liver by ten hours in the healthy man, reaching a maximum of more than 90% and then decreasing steadily to 70% by fifty hours, whereas in Wilson's disease the greatest concentration in the liver never exceeded 50%

Study of the specific activity of the copper in the urine supports the theory that, in healthy people almost all the injected copper becomes firmly bound to protein by twenty-four hours, whereas in patients with Wilson's disease it mixes with a large body pool of copper and remains readily available for excretion at the glomerulus

We wish to thank Dr Michael Ashby, Dr H Kryszek, and Dr S Nevin for permission to study patients under their care, Mr B R Payne and his associates at the Atomic Energy Research Establishment, Harwell, for their invaluable help in supplying copper of very high specific activity, and Dr W P Kennedy, of the Distillers Company (Biochemicals) Ltd, for a most generous gift of penicillamine.

THE CLINICAL SIGNIFICANCE OF STERNAL TENDERNESS

THE VALUE OF SELECTIVE MARROW BIOPSY IN MALIGNANT DISEASE

N D GOWER
M B Lond
SENIOR REGISTRAR IN PATHOLOGY,
EDGWARE GENERAL HOSPITAL, LONDON

BONE tenderness in hæmopoietic disorders is well known (Wintrobe 1946, Witts 1946, Whitby and Britton 1953), and may affect any bone, most commonly the sternum, particularly in leukæmia, polycythæmia, and myelomatosis Less attention has been paid to the occurrence of bone tenderness in association with metastatic neoplasms and reticuloses, although some workers have reported that diagnostic material may be aspirated more regularly from tender than from non-tender bone

CORRELATION BETWEEN DIAGNOSIS AND STERNAL TENDERNESS IN 200 CASES

Diagnosis	No of cases in which sternal tenderness was	
	Present	Absent
Carcinoma malignant cells present in marrow film	15	2
Carcinoma malignant cells not found in marrow films	1	22*
Myeloid reticulosis	6	0
Reticuloses without evidence of marrow involvement	0	5
Myelomatosis	6	5
Plasmacytoma, apparently solitary, with normal bone-marrow	0	3
Acute leukæmia	5	7
Chronic leukæmia	1	9
Polycythæmia vera	2	2
Myelofibrosis	0	3
Megaloblastic anæmia	15	22
Other ' primary " cytopenia	3	6
Hæmolytic anæmias	0	7
Iron-deficiency and miscellaneous anæmias	7	46
Total	61	139

* 2 of these cases were found at necropsy, one and four weeks later, to have marrow metastases In 1 case the sternal-puncture needle had been inserted between two nodules of growth

Whitby and Britton (1953) and Lopes Cardozo (1954) recommend puncture of tender bone in the diagnosis of secondary carcinoma

Amy and Jaimet (1953) and Jaimet and Amy (1956) emphasise the importance of selective puncture of tender bone in patients presenting diagnostic problems, and report the finding of tumour cells in the marrow in unsuspected cases of neoplasm

Varadi (1955) found Sternberg-Reed cells in the marrow of five patients with Hodgkin's disease by "aimed" puncture of tender parts of the sternum This degree of success is in sharp contrast to that of other writers on the subject (Cooper and Watkins 1949, Baryd et al 1954)

Marrow puncture, however, is still generally done as a blind biopsy of either the iliac crests or the upper part of the sternum Although this is satisfactory in the diagnosis of hæmopoietic disorders it probably accounts for the comparative rarity with which neoplasms are diagnosed by marrow examination

Method

To assess the frequency and significance of tenderness 200 consecutive patients about to undergo marrow puncture were examined for tenderness of the sternum The bone was palpated from the manubrium downwards, firm pressure being made with the ball of the index finger Many healthy people complain of discomfort over the lower third of the sternum when examined by this method, therefore tenderness was regarded as present only if it was very definite Most of the patients who experienced tenderness on palpation also complained of pain on light percussion of the sternum, but the tenderness was elicited less constantly in this way

Marrow was aspirated from these tender spots or, if tenderness were absent, from the sternum at the junction of its upper two-thirds and lower third

Results

Of the 200 patients 61 were considered to have tenderness of the sternum In most cases the tenderness was quite sharply localised to small areas, usually in the lower third of the sternum Diffuse sternal tenderness was seen in a few cases of metastatic carcinoma, myelomatosis, acute leukæmia, and, most noticeably, in 4 of 6 patients with myeloid reticulosis as defined by Israëls (1951) In these patients generalised bone tenderness and spontaneous bone pain were usual

The diagnoses and presence or absence of sternal tenderness in the 200 patients is summarised in the accompanying table

Although sternal tenderness was found, as expected, to be common in patients with neoplastic blood disorders and in those with bone-marrow metastases, it was not confined to these groups of patients, nor was it found as often as expected in patients with leukæmia or with myelomatosis In the megaloblastic anæmias sternal tenderness was found only in severely anæmic patients, it disappeared with successful treatment, as in the leukæmias, but very much more rapidly, usually being absent after three or four days and indicating improvement in advance of the rise in hæmoglobin level, sometimes even before the reticulocytosis began The patients with non-hæmopoietic malignant disease studied did not form a representative sample of all such cases in the hospital being biased in favour of cases with known or suspected metastases in the marrow Even so, selective puncture of tender areas of bone proved of diagnostic value in some instances

Illustrative Case-reports

Case 1.—A man, aged 60, with carcinoma of the prostate, developed refractory normochromic anæmia No primitive cells were found in his peripheral blood Radiography of his skeleton showed no evidence of metastases in bone The acid and alkaline phosphatase levels in the serum were normal The blood-urea level was 80 mg per 100 ml, and it was thought that the anæmia might be secondary to renal impairment, but puncture of a tender sternum revealed clumps of carcinoma cells Simultaneous puncture of the non-tender left iliac crest yielded normal marrow

Case 2.—A man, aged 47, was admitted to hospital for the investigation of sciatica Radiography showed collapse of a lumbar vertebra, and the peripheral blood showed leuco-erythroblastic anæmia A diagnosis of secondary carcinoma was considered, but no primary growth was found Marrow aspirated from a sharply localised tender area of the sternum showed masses of abnormal reticulum cells, yet simultaneous puncture 1 cm above the tender spot yielded normal marrow The diagnosis of myeloid reticulosis was confirmed at necropsy

Case 3—A woman, aged 76, was admitted to hospital for the investigation of cervical lymphadenopathy She had no anæmia, but her peripheral blood showed neutrophil leucocytosis Lymph-node biopsy showed a necrotic tumour on which no firm opinion could be given The sternum and ribs were tender, and metastatic carcinoma was diagnosed by sternal puncture Necropsy disclosed a small carcinoma of the stomach with metastases in lymph-nodes, liver, and bones

Conclusions and Summary

Bone tenderness, in particular sternal tenderness, may develop in patients with various disorders but is particularly common in those with bone-marrow metastases and those with myeloid reticulosis

Selective puncture of tender bone will improve the chances of finding abnormal cells in such cases

Selective puncture of the marrow is recommended in the investigation of obscure cases, particularly if unexplained anæmia, bone destruction, or lymphadenopathy is present

It is a pleasure to thank Dr George Discombe for his advice and for his criticism of this paper

SEX REVERSAL:

OVARIAN TISSUE ASSOCIATED WITH MALE NUCLEAR SEX

D J B Ashley
M D Lpool
SENIOR REGISTRAR IN PATHOLOGY,
DAVID LEWIS NORTHERN HOSPITAL,
LIVERPOOL

C H Jones
M D Lpool
ASSISTANT PATHOLOGIST,
ALDER HEY CHILDREN'S
HOSPITAL, LIVERPOOL

The syndrome of gonadal dysgenesis, Turner's syndrome, is now a well-recognised, although uncommon, disorder of sexual development In its classical form it is characterised by female (or near female) bodily habitus, atrophic gonads, absence of secondary sex characters, amenorrhœa, and increased urinary excretion of pituitary gonadotrophic hormones Often there are associated congenital defects—notably short stature, webbing of the neck, and cubitus valgus The principal anomaly is in the gonads, which are represented only by a primitive genital ridge consisting of connective tissue and a few mesonephric remnants (Wilkins and Fleischmann 1944, Grumbach et al 1955)

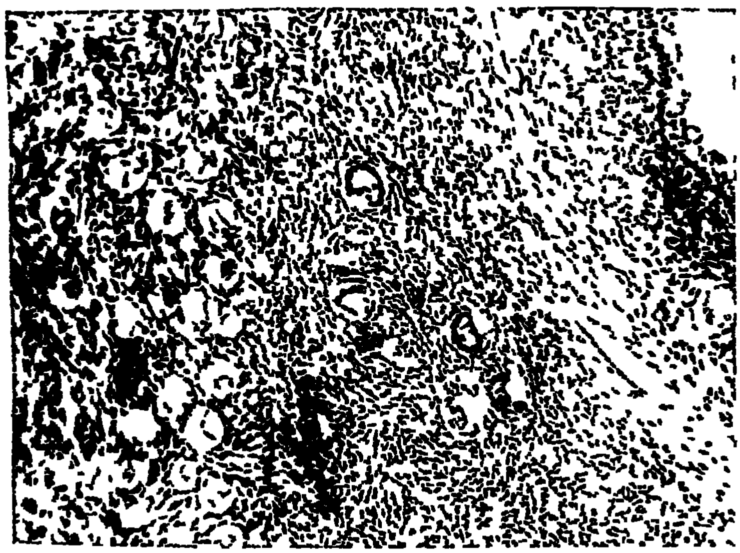
Recently it has become possible to determine the "genetic" sex of an individual by examining the cell nuclei of the skin (Moore, Graham and Barr 1953) and of the buccal mucosa (Moore and Barr 1955) Though it has not been rigidly proved that the chromatin bodies seen in a high proportion of the cells of normal females are the XX-chromosome complex, the presence of these bodies is generally held to indicate the female genotype (Lennox 1956) These tests of genetic sex have been applied to many people with Turner's syndrome, and it has been found, in most cases, that the epithelial cells are chromatin-negative—i e, that the genetic sex is probably male (Polani, Hunter, and Lennox 1954, Grumbach et al 1955) This view is upheld by this syndrome's association with coarctation of the aorta, a congenital anomaly normally largely confined to males, and by the observation (Polani, Lessof, and Bishop 1956) that 4 of 25 patients with Turner's syndrome had anomalies of red-green colour-vision, a defect inherited as a sex-linked recessive characteristic and ten times commoner in males than in females

The case we report here may be discussed within the general framework of Turner's syndrome but presents certain anomalous features and shows a much closer analogy with the syndrome of testicular agenesis (Klinefelter et al 1942)

Case-report

An only child was referred to Alder Hey Children's Hospital at the age of 10 days because of doubts about the "true sex" The baby had labia majora and minora and a phallus suggestive of an enlarged clitoris on which there was a hypospadiac urethral opening through which urine passed In front of the anus was a vagina with a second urethral opening on its anterior wall It was found subsequently that a single urethra left the bladder but divided into two after a short course Otherwise the baby, though small, was apparently normal, with no evidence of cardiovascular or skeletal abnormalities The bone age at 18 months corresponded to the chronological age The urinary excretion of 17-ketosteroids, determined on three occasions in the first 9 months, was 0 64, 0 22, and 0 25 mg daily These results are within the normal range for this age (Wilkins et al 1955)

Laparotomy at 17 months of age revealed a uterus and fallopian tubes of normal size The two ovaries, in their normal position, were slightly enlarged and cystic There was no sign of testicular tissue retroperitoneally or in the inguinal canals or



Biopsy of ovary at one edge can be seen part of the wall of a follicular cyst, while the remainder of the tissue shows many oogonia and immature graafian follicles (Hæmatoxylin and eosin ×110)

of any definite structures of wolffian origin A small piece of the right ovary was removed for microscopy Sections showed that the specimen contained a follicular cyst and that many oogonia were present, although formed graafian follicles were few (see figure)

Other investigations —Smears of the buccal mucosa were taken from both sides of the mouth on four occasions and were examined for the presence of " sex chromatin " A skin biopsy was similarly examined In every instance the proportion of cells showing the " sex chromatin " was less than 6%, a figure well below the lower limit seen in normal females Blood-films were also examined for " drumsticks " in the polymorphonuclear leucocytes (Davidson and Smith 1954) Three separate films were examined, and in each more than six " drumsticks " were seen in an examination of five hundred cells

Follow-up —At the age of 20 months the child was thriving

Discussion

This case presents several unusual features Clinically the appearance was of a female infant with an enlarged phallus She could therefore be regarded as a case of female pseudohermaphroditism Examination of the skin and buccal mucosa revealed that the nuclear sex was male, and that she should therefore be considered as a case of Turner's syndrome with enlargement of the phallus (Grumbach et al 1955) The finding of a female frequency of " drumsticks " on the polymorphonuclear leucocytes need not be regarded as invalidating the diagnosis of the genetic sex from the epithelial cells Ashley (1957) has shown that the sex-chromatin mass on the nuclear membrane and the " drumstick " on the polymorphonuclear leucocyte are not identical, and similar discrepancies have been seen in other cases of gonadal dysgenesis (Greenblatt 1957)

The histological appearances of the ovary present a much more serious discrepancy This case is the only one which can be traced in which the gonad of an individual of male nuclear sex shows the histological features of an ovary, all the usual structures of the ovary, including germinal elements, are present

Female Pseudohermaphroditism

The diagnosis of female pseudohermaphroditism must be considered first This condition is seen in adrenal cortical hyperplasia (Broster et al 1953) when the adrenal glands produce excessive amounts of androgenic hormones causing masculinisation of the female and precocious virilism Such persons are of female nuclear sex The present patient showed no evidence of virilism, she had no growth of sexual hair, and her excretion of urinary 17-ketosteroids was within normal limits for her age There is also a group of female pseudohermaphrodites without adrenal hyperplasia Few recent reports of this condition have been made Armstrong (1955) included 2 cases in a review of diversities of sex and found that the nuclear sex in both was female

Turner's Syndrome

The occurrence of individuals of male genotype—i e , absence of the sex-chromatin body from the resting nuclei of the cells of the skin and buccal mucosa—with female phenotype, female bodily habitus, and internal genitalia arising from the mullerian ducts, is now well recognised Most of these cases belong to the group usually called Turner's syndrome, the main features of which are outlined above, and usually show no evidence of masculinisation except for the few instances in which there has been enlargement of the phallus, 3 such cases have been reported recently (Gordan et al 1955, Grumbach et al 1955) in which laparotomy and section of the gonad showed the usual spindle-celled connective-tissue stroma and mesonephric remnants of the gonad of Turner's syndrome together with the presence of nests of " Leydig " cells in the medullary regions These cells have been recorded in the gonad of cases of the syndrome without enlargement of the clitoris, yet clitoral hypertrophy may be related to the functional activity of such cells Cells of this type were not found in the biopsy specimen taken from our patient, which was, however, taken from the peripheral part of the ovary

Turner's syndrome is usually regarded as due to a failure of the primitive indifferent gonad to develop at all, possibly because of failure of the germ cells to migrate into it, or because of some as yet unknown environmental factor (Polani et al 1954, Grumbach et al 1955, Lennox 1956, Segal and Nelson 1957) The failure of gonadal differentiation leads to the development of a " neuter " state which, in mammals, appears to be morphologically more closely linked to the female form than to the male This is confirmed by the well-known female form of the eunuch and by the classical observation of Jost (1953) that rabbits castrated early in intrauterine life develop into morphologically female adults

Gonadal Agenesis

It is impossible to reconcile the histological appearance of the ovary in the present case with any theory of gonadal agenesis The gonad, far from remaining as a primitive indifferent genital ridge, has developed into an organ which is an apparently normal infantile ovary containing germ cells Wilkins (1957) includes in his discussion of Turner's syndrome a group of cases in which a small amount of ovarian germinal tissue is present and to which he gives the name gonadal hypoplasia Kerkhof and Stolte (1956) described 2 of these cases in adult women, both of whom complained of primary amenorrhœa and were of female habitus with hair growth of female distribution and normal urinary excretion of gonadotrophic hormones A small biopsy specimen from each ovary showed the typical appearances of gonadal agenesis in one woman, and in the other woman solitary primordial follicles were seen in both ovaries and there were two follicular cysts, the remainder of the tissue consisting of ovarian stroma Since the 2 patients were clinically similar it was assumed that germ cells had been missed in the biopsy specimen from the first case In both these cases, however, the nuclear sex was female A similar case was described by Hoffenberg et al (1957, case 2), whose patient was exceptional in that she had

had irregular menstruation between the ages of 15 and 21 Sections of her ovaries showed many primordial follicles The nuclear sex was not determined, but the polymorphonuclear leucocytes were of female type In these cases the concept of hypogonadism is tenable, but in the present case this hypothesis will not explain the apparent reversal of the genetic sex

A case which more nearly resembles the present one in the histological appearances of the ovary was described by Atria et al (1948) It was clinically typical of Turner's syndrome in that the patient was stunted, had webbing of her neck, cubitus valgus, and underdeveloped breasts and pubic hair, and had never menstruated The level of follicle-stimulating hormone in the urine was raised At necropsy, at the age of 20, infantile internal genitalia were found the hypoplastic ovaries each weighed about 2 5 g and contained many primordial follicles with oogonia The nuclear sex is not stated If it was male, the concept of Turner's syndrome as a manifestation of intrauterine gonadal failure would have to be reconsidered

Klinefelter's Syndrome

The condition of our patient may be regarded as an analogue or mirror image of Klinefelter's syndrome with female nuclear sex (Klinefelter et al 1942), in which all grades of testicular development, from a simple mass of Leydig cells to a complex tubular system showing spermatogenesis, may be found (Bunge and Bradbury 1956, Segal and Nelson 1957) These two conditions—Klinefelter's syndrome with female nuclear sex, and the syndrome exhibited by the present patient—are instances of complete sex reversal, the genetic sex revealed by examination of the cell nuclei and the phenotypic sex revealed by the bodily habitus and the histological appearance of the gonad being diametrically opposed

A theory which offers an explanation of this discrepancy has been published by Hoffenberg and Jackson (1957), who postulate the presence of an evocator (itself normally determined by the genetic constitution of the individual), which determines the direction of differentiation of the primitive gonad and thence of the development of the wolffian or mullerian-duct systems They suggest that, in Klinefelter's syndrome, the male evocator is in the ascendant, and that the gonad is thereby stimulated to develop in the direction of a testis Such a theory, in reverse, would explain the findings in the present case, and, with the extension that the full effect of a female evocator may not be apparent on the cells of an individual who is genetically male, would explain the embryogenesis of the commoner cases of Turner's syndrome with gonadal agenesis

True Hermaphroditism

A further possibility which must be mentioned is that the child is a true hermaphrodite having both testes and ovaries or ovotestes This could not be definitely excluded without serial sections of the whole of both gonads, but we think it extremely unlikely in view of the normal appearance of the ovaries, the perfect development of the mullerian-duct system, and the absence of any identifiable ectopic testicular tissue or wolffian structures

It will be interesting to see whether this child attains a normal stature and has a normal puberty Surgical reconstruction of the external genitalia will be carried out later At present her ovaries are histologically normal for her age, but it is possible that the cells, being of male genetic sex, will be unresponsive to the pituitary hormonal stimulus of puberty Perhaps such unresponsiveness would explain the condition of the patient described by Atria et al (1948), although in the absence of knowledge of the nuclear sex this is only speculation Against such an explanation must be set the fact that one of the patients of Hoffenberg et al (1957) menstruated despite agenesis of the gonads, as did 2 patients of Polani (1957) with male nuclear sex, in whom, however, laparotomy was not performed

Summary

A case of anomalous sexual development is described in which the bodily habitus and sexual organs were of female morphology except for enlargement of the clitoris, and the ovaries appeared histologically normal for the age of the patient, but the nuclear sex was male

The concept of Turner's syndrome is reviewed, and it is concluded that the embryogenesis in the present case can best be explained as due to the ascendancy of an abnormal female evocator acting on the indifferent gonad in the earliest days of intrauterine life, and that failure of development of the gonad may not explain the ætiology of this syndrome

ADDENDUM

Since this paper was submitted for publication similar cases have been recorded by Prof R B Greenblatt at the 1957 Laurentian Hormone Conference, and by Hoffenberg and Jackson (case 20) (*Brit med J* 1957 ii, 1457)

We wish to thank Dr R H White-Jones, who referred the case, and Miss I Forshall, F R C S, under whose care the baby was admitted to hospital, for permission to publish, and Dr E G Hall for criticising the manuscript A summary of this case-report was read at the symposium on Nuclear Sexing held at King's College Hospital, London, on Sept 6, 1957

INTRATHECAL PHENOL FOR INTRACTABLE PAIN*

SAFETY AND DANGERS OF THE METHOD

P W NATHAN

NATIONAL HOSPITAL, QUEEN SQUARE, LONDON, W C 1

AT the back of the minds of those who treat patients with intractable pain, there is always the hope that a substance may be found which will destroy the nerve-fibres conducting impulses subserving the sensation of pain, while leaving intact all other fibres With such a substance, a selective chemical posterior rhizotomy might be carried out by intrathecal injection It was, then, with much interest that we heard that Maher was treating the severe pain of cancer by the intrathecal injection of substances thought to unite with nervous tissue

In 1955 Maher published his first results of treating pain in cancer by the intrathecal injection of phenol in glycerin and of silver nitrate in water and glycerin; in 1957 he reported further results, using phenol dissolved in glycerin and ethyl iodophenylundecylate (‘Myodil’), and silver nitrate in a solution of phenol in glycerin.

These solutions were injected with the patient lying in such a position as to allow the solutions, which are heavier than cerebrospinal fluid (C.S.F.), to flow into the arachnoid sac surrounding the selected nerve-roots. When given in this manner, the full concentration of the solution falls on about two roots, with little or no effect on neighbouring roots. Maher noted that the substances affected the function of the nerve-roots within a few minutes and that the maximal effect passes off within 10 to 15 minutes. The patient, after lying in the required position for a quarter of an hour, can then move into a sitting position, without any further manifestations of the action of the substances on the nerve-roots.

Anyone hearing of this method of dealing with intractable pain will want to know if it is effective and if it is free from danger. We report here an investigation of the toxicity of phenol in myodil and of silver nitrate in phenol and glycerin, injected intrathecally in quantities of 1 ml. or less. We are not reporting our results obtained in relieving pain—suffice it to say that we have obtained relief in about a half of the cases—nor are we now reporting our investigation of the mode of action of phenol on nerve fibres. Although we have so far had the opportunity of testing Maher's method in only a few cases, our limited experience may be useful to others who have the problem of helping patients with intractable pain.

Undesired side-effects are seen with most methods used in the treatment of the chronic pain of cancer. Analgesic drugs often cause nausea, light-headedness, and drowsiness; anterolateral cordotomy has complications such as disturbed bladder control; and leucotomy may give rise to defects of judgment, initiative, and intellectual capacity. Intrathecal injections might result in a reactive meningitis or arachnoiditis, in paraplegia, or in damage to nerve-fibres which should be preserved. Changes in C.S.F. cell and protein contents have been looked for as a possible indication of damage to and reaction of the surrounding tissues, and in particular of the meninges. The rate of diffusion of phenol out of myodil into the C.S.F. has been studied, for it is likely that the toxic effects of phenol occur when its concentration in the C.S.F. rises above a certain level.

In all but a few cases reported here the phenol in myodil has been a 7.5% solution; in the remainder it has been a 5% solution. We report only the results of injecting the stronger solution, for if such a solution may be used with impunity, then the weaker solution is likely to be innocuous. The 7.5% solution of phenol in myodil was given in amounts of 0.75, 1.0, or 1.5 ml. The silver nitrate could not be given in watery solution, for then some of the phenol would be present in watery solution, and it is essential that the phenol should remain in solution in a lipid. Accordingly the silver nitrate was dissolved in as small a quantity of water as possible, and this small quantity of solution was added to a 5% solution of phenol in glycerin; 0.75 ml. of this solution was injected. These solutions were injected intrathecally caudal to the 12th thoracic vertebra in all cases, except in three, in which the injections were made immediately caudal or cranial to the 7th cervical vertebra.

Observations

Evidence of Undesired Side-effects

Phenol in myodil.—Thirty injections of phenol in myodil have been given.

In no case has any weakness of the musculature followed the injection, even when invasion of the peripheral nerves by cancerous tissue had already caused some weakness. After one of the injections, the patient had retention of urine and such diminution in anal sensation that he did not know when fæces were being passed; this patient had had a very slight disorder of defæcation before the injection, due to infiltration of the pudendal nerves by a cancer originating in the rectum. Following the other twenty-nine injections, micturition and defæcation were unaffected.

Silver nitrate in phenol in glycerin has been injected in thirteen cases.

There was a slight increase in weakness of an already affected limb in six, an increase in an already disturbed control of micturition in two cases, and an increase in an already disturbed control of defæcation in one. In one patient, who had a carcinoma of the breast with metastases, anæmia, and diabetes mellitus, the injection was followed by a severe meningeal reaction. 2 days after the injection the patient died. Since this experience no further injections with silver nitrate have been carried out.

Necropsy Evidence of Toxicity

Phenol in myodil.—As seven of the patients who had this injection have eventually died from cancer, it has been possible to determine changes brought about by the injection. In none was there any macroscopic abnormality which could be attributed to the injection.

There was no fibrosis outside or inside the spinal theca; the meninges were not thickened and the pia mater and arachnoid membrane were of normal appearance. The nerve-roots appeared normal, in so far as they were not involved by the cancerous tissue; they were neither bound down by adhesions nor thickened nor shrivelled.

The histological investigation of the nerve-roots from these cases and from cats treated in the same way is being undertaken by Dr. Marion Smith; the results of this investigation will be reported later.

Silver nitrate in phenol in glycerin.—Five of the seven patients mentioned in the previous paragraph, showing no gross abnormality attributable to the injections, had also had injections of the silver nitrate solution.

However, as has been said already, in one patient a marked meningeal reaction developed after an intrathecal injection given in the lower cervical region. In this case leptomeningitis was found at necropsy; this was most intense caudal to the 8th cervical vertebra, where the injection had been given. The reaction involved the whole of the pial sac. It was greatest in the lower thoracic region and more evident posteriorly than anteriorly. This distribution was probably due to the position—half sitting up—in which the patient had been nursed after the injection.

Evidence of Toxicity as Judged by Changes in Cerebrospinal-fluid Constituents

Phenol in myodil.—In nine patients specimens of C.S.F. were taken and examined after the intrathecal injection (table I).

In eight patients the cells were counted and the protein estimated both before and after the injection; in one, no specimen was taken before the injection. The specimens were taken at various intervals after the injection. There were few consistent changes. In one patient there was definite slight polymorphonuclear leucocytosis in the fluid 24 hours after the first injection, but it did not recur 24 hours after a second injection. In these nine patients the maximal effects were a polymorphonuclear leucocytosis of 73 per c.mm. 24 hours after an injection, and an increase in protein content from 90 mg. per 100 ml. to 140 mg. in 5 days, and the minimal

effects were no change in the cell count and an increase in protein from 90 mg to 95 mg per 100 ml in 5 days These changes, however, may be regarded as very slight

Silver nitrate in phenol in glycerin—In very few patients was the C S F examined after the injection of silver nitrate 0 81 mg (gr $^1/_{80}$) dissolved in water and added to a solution of phenol in glycerin) The findings in these specimens are given in table II Apart from the death from chemical meningitis, the results do not suggest that this form of injection is very toxic

Rate of Diffusion of Phenol out of Myodil into C S F

Phenol acts on tissues differently according to whether the solvent is water or a lipid As the phenol injected into the C S F in myodil or glycerin is immediately surrounded by an aqueous fluid, it is important to know its rate of diffusion into the C S F It is evident that the amount diffusing into the C S F produces no marked reaction; for the changes in the cellular and protein constituents of the fluid are slight

In the first instance observations were made on the diffusion of phenol into C S F in vitro Later, the diffusion in patients was determined by taking specimens at intervals after the intrathecal injection

The *method of estimating phenol* was similar in the in-vitro and in-vivo experiments For the estimation in the in-vivo experiments, 1 ml of C S F was added to 4 5 ml of Folin and Ciocalteau's reagent diluted 1 3 with water The precipitated proteins were centrifuged, and to 5 ml of the supernatant fluid was added 2 5 ml of 20% sodium carbonate solution (w/v) The tube was placed for 5 minutes in a waterbath at 37°C to bring up the blue colour, this was compared with that of a standard solution containing 0 1 mg of phenol, which had been treated similarly In the in-vitro experiments it was found that the C S F contained so much phenol that it was necessary to dilute it with distilled water before the estimation of the phenol The amount of dilution necessary to give a satisfactory final colour was found by trial and error As a result of this dilution, it was found unnecessary to centrifuge the specimen after the addition of dilute Folin and Ciocalteau's reagent, for the protein had been " diluted out " Generally, a 1 in 10 dilution was found to be most satisfactory 1 ml of this was added to 3 ml of water in a test-tube, followed by 3 ml of dilute Folin and Ciocalteau's reagent and then by 2 5 ml of the sodium carbonate solution A standard was prepared in the same way, using 0 1 mg of phenol in 1 ml, and the colours developed were compared

Procedure of in-vitro experiments—25 ml of normal C S F was layered carefully on top of 3 ml of 10% phenol in myodil in a 50-ml measuring cylinder To prevent turbulent mixing of the two liquids, the C S F was delivered upwards by means of a pipette, the end of which had been made J-shaped The fluid was covered with a layer of liquid paraffin to avoid evaporation of phenol The measuring cylinder was then incubated at 37°C for 22 hours

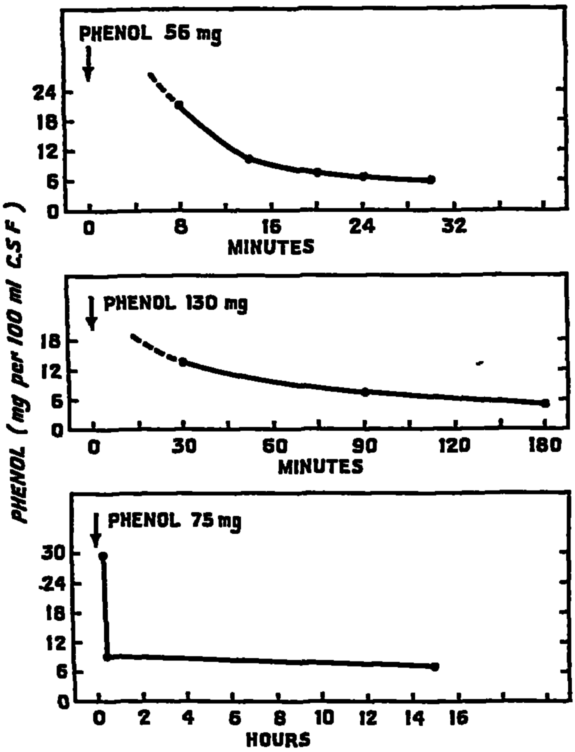
At intervals of ½, 1½, 3½, 6½, and 22 hours, 1 ml of C S F was slowly removed from the centre of the column, and its phenol content was estimated The concentration of the phenol at the centre of the fluid column was taken as representative of that of the whole column, on the assumption that the phenol diffusion gradient was linear

TABLE III—RATE OF DIFFUSION OF PHENOL FROM MYODIL INTO C S F IN VITRO

Times from start of experiment at which specimens were taken (hr)	Percentage of phenol transferred from myodil into C S F
½	4 0
1½	9 3
3½	14 7
6½	25 5
22	32 1

Results of in-vitro experiments—The results of a typical experiment are presented in table III In the actual experiment reported, the surface area of the liquid interface in the graduated cylinder was 6 2 sq cm , the calculated rate of diffusion was 4 5 mg per sq cm in the first 1½ hours At first there was a rapid diffusion of phenol out of the myodil , as the concentration in the supernatant C S F rose, the diffusion took place more slowly

Procedure of in-vivo experiments—In fourteen patients, the local concentration of phenol in the C S F was estimated It was assumed that there was no phenol in the C S F before the injection , the amount of phenol in body fluid is known not to exceed about 0 5 mg per 100 ml —an amount considered insignificant in relation to that injected The specimens of C S F were taken either through the needle by which the injection had been made (but only after C S F had been allowed to flow through the needle to wash out all traces of the myodil solution) or through another needle one vertebral space caudally When the fluid was withdrawn at intervals up to 35 minutes after the injection, the patient was not moved from



Graphs to illustrate the rate of diffusion of phenol out of myodil into the local C.S F in 3 of the patients

the lateral position When the fluid was withdrawn at intervals of hours or days after the injection, the patient was allowed to move about normally

For the first 24 hours after an injection, however, the patient was kept in a sitting or semi-sitting position, to prevent the phenol in myodil from flowing rostrally into the cranial cavity After that time he was allowed up and no restrictions were placed on his walking about The specimens of fluid then taken were local to the site of the injection When a patient lies in the lateral position, myodil, being heavier than C S F, spreads locally for about the depth of a vertebra in each direction from the point of the injection After the patient has been sitting or standing, the myodil collects at the bottom of the thecal sac, as shown by X-ray examination, in this case the myodil is caudal to the point of the needle through which the sample is being taken

Results of in-vivo experiments—The rates of diffusion of the phenol out of myodil into the local C S F are shown graphically in the figure, each curve gives the findings in a different patient All other results were similar to these examples It is apparent from the figure that the phenol content of the C S F in the immediate neighbourhood of the injection was relatively high soon after the injection, it fell considerably within the 1st hour, after the 1st hour, and during the subsequent days, the fall was only very slight In every case the initial phenol content of the C S F was always the highest

Although in the in-vitro experiments the amount of phenol transferred to the C S F continued to rise during the first 24 hours after the injection, such diffusion was not found in the in-vivo experiments There may be several reasons for this The phenol is taken up by nervous and other tissue, the C S F surrounding the phenol in myodil is constantly flowing, so that fluid with a relatively high phenol content is removed or diluted by uncontaminated C.S.F It is seen radiologically that the myodil containing phenol breaks up into droplets to some extent, thereby increasing the interface between the myodil and the C S F and permitting more rapid diffusion And it is possible that phenol may be removed from the C S F into the vascular bed

The effects of phenol on nervous conduction are manifest $1^1/_2$ to 2 minutes after the injection, rising to their maximum within $^1/_2$ minute, and tending to pass off in 10 minutes From the physiological effect it would appear that the amount of phenol leaving the myodil, and eventually being fixed in the nervous tissue, must be great within the first 5 minutes This rapid transfer is not apparent in the figure, the fall alone is shown on the graphs We do not know what content of phenol in watery solution is needed to block nerve-fibres The reason why the patient can be moved within 15 minutes of the injection is probably that the concentration of phenol in watery solution is then too small to affect the nerve fibres, by that time the phenol has been taken up by the nervous and other tissues, and an appreciable quantity has passed into the C S F In some cases no therapeutic effect, and even no local anæsthetic effect, was obtained It is apparent from the manner in which the phenol leaves the myodil that if there is no effect within the first few minutes, there will be none subsequently, and that in fact is what has always been found

Discussion

In view of our experience, intrathecal injection of silver nitrate in phenol and glycerin seems to be dangerous, when performed in the cervical region The intrathecal injection of phenol in myodil in the concentration used is safe, and we consider that this method is worthy of trial before surgical division of sensory pathways is undertaken

It is 90 years since Lister introduced phenol as an antiseptic into medicine Experience has shown that phenol is toxic, and so it comes as a surprise to hear that it can be injected intrathecally in fairly strong solution

The effect of phenol on tissues and organisms varies according to the solvent used In watery solution phenol is penetrating and sclerosing, it is well known to all practising doctors that phenol in glycerin, appropriately used, is harmless Equal quantities of pure phenol and pure camphor have been used in the treatment of tinea In this form, phenol is still antiseptic and analgesic, but it is far less caustic However, observations of the effect of phenol on the skin have little bearing on the possible effects of phenol within the thecal sac, surrounded by C S F and in contact with nervous tissue

To the best of our knowledge, toxic effects have been seen only when the phenol was used in watery solution Evidence of damage to the nervous system is scanty

Greenfield et al (1955) concluded that phenol, "if introduced in considerable concentration (0 5%) would be expected to lead to immediate lesions of the roots of the cauda equina with a corresponding symptomatology", this refers only to phenol in watery solution (Greenfield, personal communication, 1956)

Weston Hurst (1955) reported the results of an investigation in monkeys of certain substances which might be expected, when introduced intrathecally, to cause damage to the nervous system from arachnoiditis, one monkey which received intrathecally phenol (as a watery 2% solution) died after 13 days with greatly dilated ventricles. On the other hand large amounts of a dilute watery solution of phenol have been administered intrathecally to humans without causing death. Suvansa (1931) reported that he had treated tetanus by giving intrathecally 0.25% solutions of phenol in water in doses of 30–40 ml. to adults and 12–20 ml. to children. This treatment brought the patients successfully through the period of hyperexcitability of the central nervous system, but caused nephritis.

A legal case was brought in 1953 against the Ministry of Health and Messrs. Ciba. It was claimed that the small amount of a 5% solution of phenol in water that might have leaked through a hypothetical and invisible crack in an ampoule of cinchocaine (' Nupercaine ') was sufficient to cause severe arachnoiditis and consequent paraplegia; and this claim was regarded as established. It is well known to neurologists that severe meningeal reactions causing paraplegia sometimes follow spinal anæsthesia; such cases have been reported by Zeckel and Behr (1933), Kennedy et al. (1945), Kennedy et al. (1950), Macken and Martin (1950), and Greenfield et al. (1955).

Although we have emphasised that, with this method of treating intractable pain, the phenol is in lipid solution, we have shown that the phenol diffuses into the C.S.F., resulting in the presence of a watery solution of phenol within the spinal canal. However, with the amounts and concentrations used so far—recently up to 1 ml. of an 8% solution or 3 ml. of a 7.5% solution—undesired pathological effects have not followed. More severe meningeal reactions often follow air encephalography, which is a well-established diagnostic procedure. We conclude that the injection of phenol in myodil for the relief of pain, especially the pain of cancer, appears to be justified.

Summary

An investigation is reported of the toxic effects of phenol in ' Myodil ' and of silver nitrate dissolved in phenol in glycerin, injected intrathecally as a treatment for intractable pain.

The toxic effects are considered under the categories of undesired clinical effects, evidence of toxic effects found post mortem, and changes in the cerebrospinal fluid.

As phenol is relatively non-toxic in lipid solution and relatively toxic in watery solution, the rate of diffusion was investigated of phenol out of lipid solution into the C.S.F.

It is concluded that at least 1 ml. of a 7.5% solution of phenol in myodil can safely be injected intrathecally. The solution of silver nitrate in phenol in glycerin is less safe than the phenol in myodil.

We should like to thank Dr. E. A. Carmichael and Dr. J. N. Cumings, who provided us with opportunities and encouragement to carry out this investigation, and the physicians and surgeons at the National Hospital and Mr. I. R. McCaul of the Whittington Hospital, who so kindly referred patients to one of us (P. W. N.).

INTRAGLOSSAL INJECTIONS IN UNCONSCIOUS PATIENTS

AN ALTERNATIVE TO INTRAVENOUS INJECTION

JOHN BULLOUGH
M.B. Lond., F.F.A. R.C.S.
CONSULTANT ANÆSTHETIST, DARTFORD GROUP OF HOSPITALS

IN the treatment of unconscious or anæsthetised patients it is very often desired to inject stimulants, antidotes, &c., intravenously to ensure rapid onset of action. In the obese and in the collapsed adult and in young children it may be impossible to find a vein. Since intramuscular injections may take ten minutes or more to take effect, another method, with a rapid onset of action, is an advantage. Such a method is injection into any highly vascular organ. For instance, it has been common practice for many years to inject oxytocic drugs into the uterus after cæsarean section (and injections into the liver during abdominal surgery have been described). The tongue is a highly vascular and easily accessible organ. Drugs injected into the tongue start to take effect in 40–80 sec.—e.g., the tachycardia after atropine—as against 15–30 sec. after intravenous injection.

Technique

Although the injection can be made into any part of the tongue, I now insert the needle via the ventral surface because bleeding on withdrawal of the needle is less common there. The two veins on either side of the midline should be avoided. With the patient lying supine the tip of his tongue is picked up in a gauze swab between the index finger and thumb of the left hand and drawn out of the patient's mouth. The syringe is held in the right hand, and the needle is inserted directly posteriorly (vertically downwards). Volumes of up to 2 ml. may be injected. Provided a sharp needle, size 16–18, is used, bleeding is uncommon on withdrawal of the needle. Anæsthetists may prefer to lift the tongue forward with a pair of Magill's forceps, or any other pair of blunt forceps will do. In anæsthetised patients the needle may be left in situ for serial injections of analgesics, &c.

Indications

Emergencies.—In the treatment of any unconscious, comatose, or collapsed patient, whether from injury, disease, or drugs, where a rapid onset of action is necessary, this method can be used with advantage.

In anæsthetic practice.—The intraglossal route may be used for most of the drugs used—relaxants and their antagonists, analgesics and their antagonists, hypotensive drugs and vasopressors, procaine derivatives and so on. Irritating solutions mentioned below should be avoided.

Special mention should be made of suxamethonium (' Scoline,' ' Brevidil,' ' Anectine '). I give this drug intraglossally in double the dosage I would have used intravenously —e.g., 100 mg. for an adult. Paralysis usually develops 90 sec. later, depending on the vascular condition of the patient, being most rapid in healthy children, when it may start in 45 sec. Muscular fibrillations are usually absent or minimal. The effect wears off more gradually but in much the same time as after intravenous injection. A flush around the face and neck may sometimes follow for a short time.

Contraindications

Any solution known to be irritating should be avoided, except perhaps as a life-saving measure. Barbiturates should not be used, nor should solutions of tubocurarine and of phenothiazine derivatives, because a tender lump as big as a pea is left for a week or so. Dimethyltubocurarine iodide, being in aqueous solution, can be used as an alternative to tubocurarine, and gallamine can be used. Pethidine, nalorphine, atropine, and neostigmine can all be used.

Conclusion

The practice of injecting into the tongue may at first seem unæsthetic but it can be extremely useful when veins are inaccessible As an anæsthetist I have been using it for five years without mishap, and recommend it to general practitioners and anæsthetists alike As a general guide it may be safely said that any solution which can be injected hypodermically without irritation can safely be injected into the tongue It should not be practised in conscious patients, because it is rather painful

Summary

When veins are inaccessible, and a rapid onset of action is required, drugs may be injected into the tongue in unconscious patients The onset of action takes 45–90 seconds

Intraglossal injection is recommended for stimulants, antidotes, &c , in emergencies and in clinical anæsthesia Particular mention is made of the relaxant suxamethonium Irritant solutions should not ordinarily be used

PHÆOCHROMOCYTOMA OF THE URINARY BLADDER

B R B LUMB
M B St And , M R C P
MEDICAL REGISTRAR, ADDENBROOKE'S HOSPITAL, CAMBRIDGE

G A GRESHAM
M.A , M D Cantab
DEMONSTRATOR IN PATHOLOGY IN THE UNIVERSITY OF CAMBRIDGE

THIS is an account of a phæochromocytoma arising in the wall of the urinary bladder Similar cases have been recorded only twice (Zimmerman et al 1953, Pugh 1956) The tumour produced pressor amines and gave rise to a striking clinical picture which should be easily recognised if met again The scanty literature gives a false impression of the rarity of the tumour, we hope later to report several examples collected from British hospitals

Case-report

The patient is a married woman, aged 48 At the age of 13 she began to have curious attacks after micturition As soon as the bladder was emptied, she experienced forcible " thumping " of the heart, a throbbing " bursting " headache, intense pallor of face and hands, coldness of the fingers and usually sweating These attacks, which lasted for only a few minutes, took place only in summer, and they ceased with the menarche, at 15 But they reappeared in 1950, when she was 41, and were again confined to the summer months, occurring about five times a week They became more frequent and more severe until, in 1953, they followed every act of micturition and lasted about an hour and a half

She was admitted to a nursing-home in October, 1953, for observation but had no attacks She was admitted to hospital in January, 1954, for investigation Her blood-pressure varied from 160 100 to 230 110 mm Hg, and her basal metabolic rate (B M R) was +33% Intravenous phentolamine hydrochloride (Rogitine ') 5 mg produced a fall of blood-pressure from 190 100 to 170 85 mm Hg in one minute, this result was considered equivocal Renal-function tests and an intravenous pyelogram were normal, as were the electrocardiogram and chest radiograph A diagnosis of paroxysmal tachycardia, occurring in a patient with hypertension and mild thyrotoxicosis, was thought likely She was given 100 mg of methyl thiouracil daily together with phenobarbitone gr ½, t d s , discharged from hospital, and observed as an outpatient

Attacks occurred in the summer of 1954 but seemed to be less frequent and lasted only a few minutes Blood pressure readings varied from 190/100 to 220/110 mm Hg Treatment with methyl thiouracil and phenobarbitone was continued, and occasional mild attacks occurred in the summer of 1955, the blood-pressure remained about 200/100 Methyl thiouracil medication was reduced to 50 mg daily in March, 1956, and withdrawn altogether four months later, phenobarbitone was continued Although during 1956 blood-pressure readings were rather higher—250/110–270/150—the symptoms disappeared entirely from April onwards There was no radiological or electrocardiographic evidence of cardiac hypertrophy, the ocular fundi showed variation in arterial calibre, with venous nipping but no hæmorrhages or exudates and no papillœdema The patient was leading a busy life, which included a large daily newspaper round in a country district

In July, 1951, a sample of urine was tested for pressor amines at University College Hospital, London, by the cat blood-pressure method (Moulton and Willoughby 1955) It was found to contain 0 8 mg of noradrenaline per ml , indicating the presence of a phæochromocytoma Intravenous pyelography was repeated in an attempt to locate the neoplasm there was no displacement of the kidneys, and the renal pelves and ureters were normal, an indentation in the vault of the bladder was attributed to pressure from uterus or distended bowel Tomograms of the renal areas were normal No further investigations were made, and she continued to attend as an outpatient, remaining free from symptoms until January, 1957, when a bout of hæmaturia, lasting ten days, led to readmission and cystoscopy

A smooth tumour, with a broad base, was seen in the posterior bladder wall above the trigone It was considered likely to be the phæochromocytoma, and the decision was made to remove it, controlling the blood-pressure with phentolamine and noradrenaline (Helps et al 1955)

Laparotomy was done on Feb 26, 1957, and the tumour excised from the posterior bladder wall without difficulty Both adrenals were normal, and no other neoplasm was found in the abdomen The blood-pressure, measured every half to two minutes throughout the operation, varied from 120/80 to 270/170 mm Hg (fig 1) Phentolamine was given intravenously in doses of 5 mg up to a total of 15 mg On ligation of the last vein draining the tumour the blood-pressure fell to 100/80, and an intravenous infusion of noradrenaline was started, it was adjusted to maintain the blood-pressure at about 170/110 for the remainder of the operation The infusion was stopped three hours later, and the blood-pressure remained at about 115/75 mm Hg for the next twelve hours Next day it was 140/90 and it remained at, or near, this level until the patient was discharged from hospital five weeks later Her urine, examined during convalescence, contained 0 01 mg of noradrenaline per ml The B.M.R was +6%

She was seen several times as an outpatient in the next six months She remains free from symptoms and looks very well Her blood-pressure varies from 190/100 to 210/105 mm Hg and her ocular fundi show variation in arterial calibre as the only abnormality When last seen she remarked that she could never have got through the recent hot weather without her operation

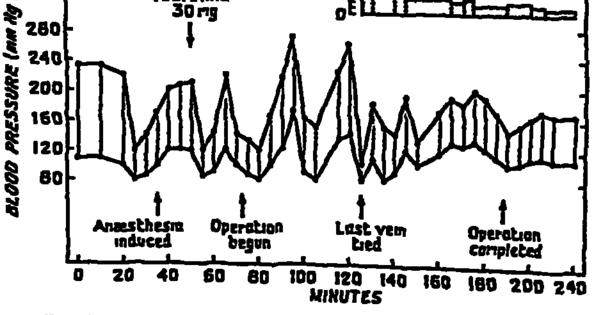

Fig 1—Blood-pressure during operation for removal of phæochromocytoma

Fig 2—Operation specimen showing a cluster of nodules on one aspect of the tumour (Actual size)

PATHOLOGY

The specimen was a roughly ovoid brown-red mass measuring 13 × 8 × 8 cm and weighing 74 g The greater part of the surface was smooth and shining, apart from a small gelatinous translucent area 2 cm in diameter A cluster of small nodules (up to 1 cm in diameter) projected from the mucosal surface (fig 2) The cut surface of the specimen showed yellow and red patches, it turned deep brown after a few hours' immersion in 10% formol saline solution The fixative became brown after a few days—a characteristic feature of phæochromocytoma

An unfixed piece of the tumour examined for pressor amines contained 2 3 mg of adrenaline and noradrenaline per gramme

Histological examination revealed trabeculæ and solid acini consisting of polygonal cells The cells contained delicate cytoplasmic granules and showed occasional nuclear pleomorphism Capillaries were abundant throughout the tumour The chromaffin reaction was not obtained Histochemical examination of the tumour cells showed lipid and protein in the cytoplasmic granules

The tumour lay outside the muscle coat of the bladder but was not clearly demarcated from it A few small islands of tumour cells infiltrated between muscle bundles Arterioles showed conspicuous intimal fibrous thickening

The close relationship of tumour cells to abundant capillaries *provided the main clue to its endocrine origin* However, without the results of biochemical investigations it is doubtful whether the neoplasm could have been recognised as a phæochromocytoma

Discussion

The clinical history and demonstration of pressor substances in the urine and in the tumour leave little doubt that the attacks both in childhood and middle life were due to squeezing of the growth by contraction of the bladder muscles Quiescence coincided with the menarche, but recrudescence cannot be related to the menopause, which has not yet arrived It seems unlikely that the tumour could have disappeared after the menarche and reappeared at the age of 41, and an alternative explanation is that it did not secrete pressor substances during the quiescent period Such intermittent activity is a characteristic feature of endocrine neoplasms

Any explanation of the restriction of symptoms to hot weather must be purely speculative

It is known that some phæochromocytomata produce mainly adrenaline and some mainly noradrenaline (Goldenberg et al 1954), and that infusion of noradrenaline causes a relatively symptomless hypertension (Barnett et al 1950) In the present case the persistently raised blood-pressure from 1953 onwards was probably associated with continuous secretion of noradrenaline We believe that superimposed secretion of adrenaline during warm weather would explain the paroxysmal attacks, a hypothesis which could be tested, in a future case, by differential estimation of the two substances in the urine by the method suggested by McMillan (1957)

The problem, then, is to account for production of adrenaline during the summer A possible clue is provided by Folkow and Von Euler (1954), *who showed that stimulation of certain* parts of the hypothalamus in the cat caused the suprarenal glands to secrete mainly adrenaline, whereas stimulation of other hypothalamic areas led to a secretion consisting mainly of noradrenaline It is not known whether human phæochromocytomata are subject to the same hypothalamic influences as the feline suprarenal medulla, but it is an interesting hypothesis If such hypothalamic control exists it could explain the postulated variation in secretion of pressor substances in the present case The intimate relationship of the temperature-regulating and sympathetic centres of the hypothalamus suggests that the activities of the one might influence those of the other Some such explanation might explain the restriction of this patient's attacks to warm weather

It is impossible to assess the significance of the apparently beneficial effect of methyl-thiouracil therapy The raised B M R in patients with phæochromocytoma is probably due to increased oxidation in the tissues, brought about by excess of catechol amines and not of thyroid hormone The normal B M R and normal urinary excretion of adrenaline and noradrenaline, after excision of the tumour, accord with this view

The blood-pressure remains moderately raised several months after removal of the tumour, a common finding in these cases (Peart 1954) The condition resembles essential hypertension, and its significance has been discussed by Goldenberg et al (1948) and Pickering (1955) This fixed hypertension was probably already present when the phentolamine test was made in 1954 and would explain the equivocal response

The structure of the tumour was not sufficiently characteristic to permit a diagnosis on histological grounds alone, and we regard its high adrenaline/noradrenaline content as much more convincing evidence of its nature The fickle chromaffin reaction is an unreliable *criterion*

Summary

A case is described in which a phæochromocytoma arose in the wall of the urinary bladder It produced pressor amines, which were detected in the urine and gave rise to characteristic paroxysmal attacks after micturition The attacks were confined to warm weather, the significance of this remarkable feature is discussed Since the histological features of such tumours are not always characteristic, the importance of estimating pressor amines in the tumour is emphasised

Preliminary Communication

A THEORY OF NERVE DEAFNESS

THREE types of impairment of hearing are generally distinguished

(1) *Conduction deafness* due to loss in the middle ear only, sensitivity for bone conduction being normal Often caused by thickening of the tympanum or by otosclerosis

(2) *Nerve deafness*, in which there is impairment of both air and bone conduction Associated with degeneration of the sensory cells of the organ of Corti in the inner ear or with other neural damage, such as a tumour of the eighth nerve

(3) *Central deafness*, which is rare and has no known peripheral origin, being regarded as a central disorder often associated with aphasia No further mention of this will be made here

There seems to be no mystery about conduction deafness, the auditory signal is simply attenuated, and this loss may usually be made good with a suitable external amplifier In nerve deafness, on the other hand, amplification does not make up for the loss, and the defect is not simple attenuation of the signal The condition has certain rather distinctive features

(1) There is some degree of confusion The older term "perception deafness", still sometimes used, indicates this clinical distinction

(2) The deterioration is mainly at the upper end of the frequency spectrum (presbyacusis), hearing for low frequencies often being normal

(3) The audiogram is generally "peaky", a sudden dip (loss of sensitivity) at about 4000 cycles being particularly common

(4) Tinnitus is common, but this may also occur in conduction deafness

(5) The curious phenomenon of loudness recruitment is common

Recruitment, which is almost certainly found only in nerve deafness, may be described as a shortening of the loudness scale

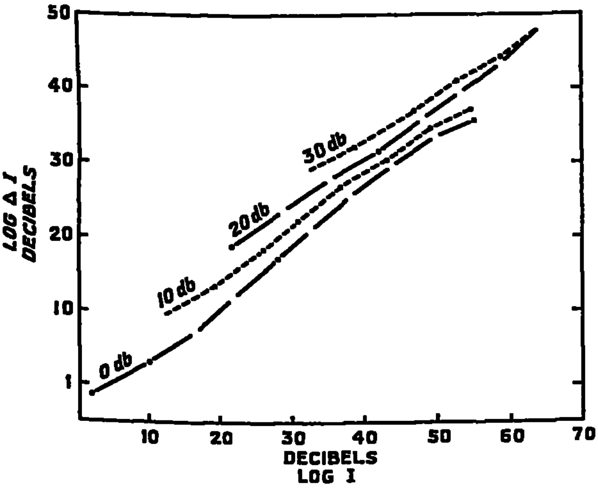

Fig 1—Effects of nerve deafness on differential threshold No additional masking has been added, tone pips are of same duration as above but following frequencies have been used 1000, 1500, 2000, 3000, and 4000 cycles per sec.

Each of 17 persons used was tested for absolute threshold at the above frequencies and compared with average ear to assess impairment for each frequency Subjects with the same absolute thresholds (i e, the same impairment) are grouped together This grouping is irrespective of frequency—subjects are combined for any frequency for which their absolute thresholds are equal Thus each subject may appear in several of the curves, at various frequencies Bone conduction to the mastoid process has been used throughout we are repeating the experiment for air conduction As in fig 1, slope flattens with increasing impairment It seems possible to estimate effective masking noise for various degrees of nerve deafness by comparing curves in figs 1 and 2 and selecting those giving best fit.

In cases of unilateral nerve deafness it may be demonstrated by applying the same tone to the two ears and asking the patient to balance the intensities for the two ears over a wide range of intensity Where there is recruitment, the deaf ear will require higher energies at the lower intensities, but, as the level rises, the difference in intensity for loudness balance decreases and may disappear In conduction deafness the ratio of the two energies will remain constant for loudness balance over the working range of hearing

Previous work on visual discrimination, where thresholds are supposed to be limited by the effective signal-to-noise ratio of the neural systems involved, suggests a possible explanation of nerve deafness We have regarded visual discrimination as limited by the channel capacity of the system, the channel capacity being a function of the number of fibres available for discrimination and the level of random neural activity, or "noise", tending to mask the signal Increase in the amount of noise should raise the threshold and tend to produce confusion Nerve deafness could be due to loss of channel capacity either through loss of functional fibres or through increased noise These two possibilities give rather different predictions

To test the hypothesis that nerve deafness is in some cases due to increased noise masking the auditory signals, we have compared the phenomena of nerve deafness with the effects of noise masking on normal hearing Their similarity is striking

Fletcher[1] found that, when he used thermal noise for masking pure tones, the high tones were primarily affected, in other words, he produced presbyacusis in the normal ear by masking with thermal noise It is well known that partial sectioning of the cochlear nerve produces presbyacusia in cats[2] and also in patients with Menière's disease[3] Thus it might be concluded that reduction in channel capacity decreases discrimination of high tones whether this reduction is the result of raised noise or of loss of functional fibres

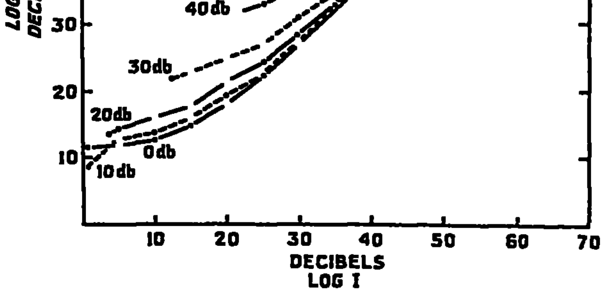

Fig 2—Effects of various levels of masking noise on threshold for detecting tone pip lasting 0 01 sec. against continuous tone Frequency of continuous tone and pip is 1000 cycles per sec Masking noise reduces slope Bone conduction was used. Pips slightly rounded to reduce transients

of the sheath, and for a mechanism which can be operated and rotated with one hand so that a finger of the free hand can be inserted per rectum to assist in the operation

Several rotatable machines have been designed on either side of the Atlantic, but in most of these the sheath has to be gripped to rotate it Accordingly the second hand is occupied, and the instrument no longer allows a free hand to examine the prostate per rectum

The resectoscope illustrated here (figs 1 and 2) is the result of attempts to fulfil the modern requirements in size, simplicity, and single-handed operating The telescope is the wide-field fore-oblique McCarthy type, which is interchangeable with all standard American patterns and gives a good clear view The grip is comfortable, and the distance between the first and second fingers has been reduced by dispensing with the lower guide-rail A light steady movement is assured by the addition of four small roller-bearings above and below the one remaining guide-rail A return spring is unnecessary because the movement is free, hence the dangerous rest position with the loop beyond the sheath, as occurs with the Baum-Rucker resectoscope, is avoided The natural movement of approximating the fingers and thumb while cutting is preferable to the Nesbit principle of cutting while extending the thumb

The sheath does not rotate on the moving parts, but the grip is equally comfortable with the instrument in the inverted position (fig 2) This enables the anterior half of the prostate and bladder neck to be resected as easily as the posterior half

Two sizes of sheath are provided 26 Charriere and 30 Charrière The smaller size is adequate for most work, the larger size enables a larger loop to be used if needed

This instrument has now been used in Bristol for the past eighteen months and has proved itself easy to operate, comfortable to handle, and simple to strip and clean Decreasing the complexity of the resectoscope has decreased the number of exasperating minor faults On several occasions more then 20 g has been resected in less than half an hour

The instrument can be supplied with duplicate telescopes, duplicate moving parts, panendoscope attachments, and two additional viewing telescopes (right-angled and retrograde) This set is completely self-contained with its own spare parts, which gives the urologist a considerable sense of security

I wish to thank Mr S T H Smith and Mr F T D Lowrie and the staff of the Endoscopic Instrument Co, Ltd of 62, Shirland-road, London, W 9, for their help and patience in the construction of this instrument

AN OBTURATOR FOR FILLING BURR-HOLES

Preoccupied as they are with good functional rather than good cosmetic results, neurosurgeons sometimes forget how serious is the circular depression in the scalp over a burr-hole We take great pains over proper apposition of the scalp edges of a wound, and very often the scar of a former craniotomy would go unnoticed except for an arc of unsightly tell-tale dents

These dents are permanent, and, even if they are covered by hair now, that man may be bald in ten years' time!

Besides the unsightliness there are two very real complications of such depressions First and most important, every stranger notices them, acquaintances point and say "Ooh, what have you had done to your head?", Operations on the head are still almost automatically associated in the lay mind with mental disorder, and from that moment that patient is suspect The second complication is not rare and depends on the propensity of some patients to finger the depressions and to imagine that they are sometimes swollen, or painful, or represent missing brain tissue

After two years' trial at the South-East Metropolitan Regional Neurosurgical Centre I am satisfied that flanged obturators made of nylon (fig 1) are effective and that their use is free from complications It is obviously desirable to have a versatile button-like plug which will fit burr-holes of different sizes, and after some experiments such a size was determined, as regards diameter of plug and width of flange, which would loosely fit into an average burr-hole finished by a no 2 or no 3 Hudson's burr, most commonly used for biopsy or craniotomy The outer surface of the button (fig 2) is ground to a convexity, and the under surface of the flange to a concavity, commensurate with the curve of an average skull, and there is a dimple in the bottom of the button to accommodate a brain nubbin if necessary It has not been found necessary to drill a hole through the centre

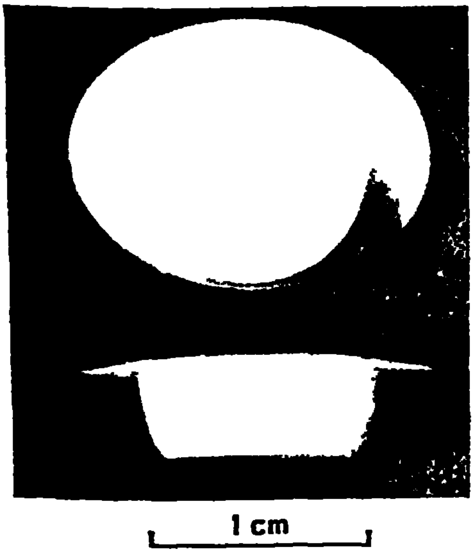

Fig 1—Obturators. Translucency is a rough guide to the requisite thinness of a flange

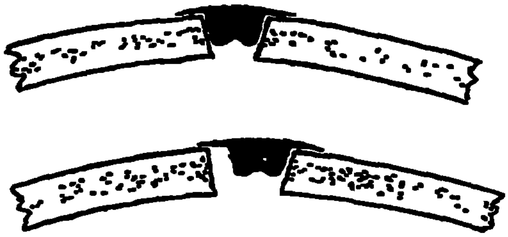

Fig 2—Showing how a single size of button is applicable to a small or large burr-hole

The button is dropped into a burr-hole in bare bone, and secured lightly either by stitching pericranium over it, or by crossing it with a stitch (before adopting this technique I had to remove a button which had been floated out of its hole by hæmorrhage beneath the flap) It is now a routine to insert them into all burr-holes except those deep to the temporal muscle

Properly made with a very thin flange, these buttons are invisible afterwards They are sterilisable by either boiling or autoclaving, are radiotranslucent, and are about a sixth of the price of tantalum discs At present they are made individually on a lathe from nylon rod, but, if the demand warranted it, a steel mould costing several hundred pounds might be made to turn them out in quantity as cheaply as a button in a draper's shop

The obturators have been dubbed "Brook buttons' and are made and supplied by Messrs Allen & Hanburys of London

Steinberg and Gardner[4] showed that white noise masking produces recruitment in the normal ear (In "white" or "thermal" random noise all frequencies are present in equal amounts, producing a hissing sound like escaping steam) Dix, Hallpike, and Hood[5] found that recruitment appears to be associated with damage to the nerve-endings at the organ of Corti but not with damage to the eighth nerve This finding is compatible with the hypothesis that neural noise produces recruitment, for disturbance of the nerve-endings (as in Ménière's disease) would be expected to produce random firing, whereas this is not generally found when fibres are sectioned

When there is marked tinnitus of a particular tone, some loss of hearing is perhaps always found near the corresponding frequency But although tinnitus is often found with nerve deafness it is not invariably found We should not expect it if the deafness was due to a tumour of the nerve, but, if the deafness was due to damage of the end-organ, the patient would presumably be aware of his neural noise as some form of tinnitus If he is not, some explanation is necessary The normal person is aware of a surprising amount of self-generated sound in a silent room, though he is not normally aware of this internal noise It is also true that we are not usually aware of irrelevant regular sounds—e g , the ticking of a clock, and even its chime, when this is familiar, though it may be loud Perhaps in some cases neural noise is rejected in a similar manner, with the result that, although it may tend to mask wanted sounds, there is no awareness of it as tinnitus, at any rate until attention is called to it

We have found it necessary, on quite other grounds, to postulate a "gate" in sensory discrimination mechanisms[6] Perhaps this postulated "gate" is raised to reject abnormally high residual noise The idea of a "gate" is important it is taken over from electronics where the term denotes a threshold introduced into a circuit so that voltages below the gate threshold are rejected The gate may be raised or lowered or may be fixed This suggests a possible connection between auditory fatigue and nerve deafness, and they have many features in common If a sustained noise or tone tends to raise the gate, we should expect recruitment (for only the lower-intensity signals will be affected by the gate) and this is in fact the case Perhaps some of the results obtained by Hood,[7] who has done much work on auditory fatigue, might be interpreted on this hypothesis Further, the neural origin appears to be the same for nerve deafness as for auditory fatigue—between the electro-cochlear activity and the binaural localisation process, according to Wever[8]

In examining the possibility that typical nerve deafness is due to raised neural noise we have compared differential intensity discrimination (short-tone pips against a continuous tone of the same frequency) over a wide range of intensities and frequencies in (1) nerve-deaf ears showing various degrees of impairment and (2) the normal ear in the presence of white noise masking We should expect the curves relating intensity of the tone pip to the continuous tone to be similar for a nerve-deaf ear and a normal ear, subject to added masking noise By determining the level of noise which produces the best fit of these curves we might hope to estimate the effective level of neurological noise in a nerve-deaf ear showing a given impairment Preliminary results are fairly encouraging, in particular we find that the curves are similar in general form These data are shown in figs 1 and 2, from which comparison may be made

If nerve deafness may be caused by raised neural noise a practical conclusion seems to follow To attempt to raise the wanted signal above the residual noise with a linear amplifier (such as a standard hearing-aid) is likely to overload the ear, for it seems clear that there is no abnormal attenuation in the system Now, it has been shown by Licklider[9] and discussed by Miller[10] that almost all the information-content of speech is carried by the changeover points, and almost none at the energy peaks, it thus appears possible to prevent overloading, while retaining the necessary information, by using suitable peak clipping in hearing aids This has been tried but has produced only slight improvement[11] Perhaps in addition it may be necessary to filter out those frequencies where impairment is greatest, because continual stimulation appears, at least in some cases, to increase tinnitus and therefore presumably the amount of neural masking noise

We wish to thank Dr E R F W Crossman, Dr T S Littler, Miss Violet Cane, and Prof O L Zangwill for helpful suggestions and advice We are indebted to Mr A S H Walford for providing nerve-deaf patients from Addenbrooke's Hospital The Medical Research Council gave a grant to one of us (J G W) and a grant for apparatus

A SIMPLE RESECTOSCOPE

Modifications of an instrument usually lead to something more complex which requires greater experience in handling The development of the resectoscope from the days of the Stern/McCarthy ratchet-driven instrument is an example of the complexities which can be superimposed on a machine of initially simple design

In the past twenty-five years the demand has been for improvement in vision and illumination, for reduction in the size

tosus (D.L.E.) Of 8 cases of D.L.E. 7 were positive for both L.E. cells and the antinuclear factor, and 1, clinically typical, negative in both tests In 3 out of 4 doubtful cases of D.L.E. the antinuclear factor was found. Of 44 sera from rheumatoid arthritis cases, 8 contained the antinuclear factor The L.E. cell test was positive in one of the latter (but the result of this test was available in only 14 of the series) In *Still's disease*, 3 out of 15 cases gave a positive antinuclear factor test, all were L.E.-cell negative. Sera from the following cases were also investigated with negative results acute rheumatic fever (11 cases) convalescent rheumatic fever (7), polyarteritis nodosa (2) dermatomyositis (1), ankylosing spondylitis (1), and doubtful rheumatoid arthritis (5).

In the positive and negative rheumatoid-arthritis group, comparisons were made between extent and activity of the arthritis, sex age, duration, E.S.R., D.A.T. and nodules Middle-aged females with a high D.A.T. and nodules appeared more commonly in the positive group The affinity of the L.E. globulin factor for white-cell nuclei of the rabbit rat, mouse, guinea-pig, chicken and toad had been demonstrated, and in the chicken and toad the nucleated red cells also took up the factor Tissue and white-cell nuclei pretreated with streptodornase fail to take up the factor

Whether the antinuclear factor was responsible for the development of L.E. remained in doubt in vivo the factor was not taken up by the cell nuclei of tissues from patients with L.E., cell nuclei took up the factor only after in-vitro incubation with the patient's own serum Thus, damage to the cell membrane or nuclear membrane seemed to be an essential prerequisite for uptake of the serum factor

Rheumatoid Arthritis of the Cervical Spine

Dr J SHARP, Mr D W PURSER, and Dr J S LAWRENCE reported that X-rays of the cervical spine of rheumatoid-arthritis patients aged 55–64 had been compared with those of individuals in this age-group selected at random from the general population. The features indicative of rheumatoid arthritis appeared to be narrowing of multiple discs, particularly the upper two (with relatively little osteophytosis of the vertebral bodies and a tendency to erosions rather than sclerosis of the adjacent plates), vertebral subluxation (particularly through narrowed discs or at multiple levels), and erosions of apophyseal joints

Using these features as criteria, 427 radiographs taken from random samples of the general population in the age-group 55–64 were examined in an effort to recognise the subjects suffering from rheumatoid arthritis The films were read without knowledge of the clinical or serological findings or of the radiological findings elsewhere.

The prevalence of these changes was found to be 6% in males and 7% in females (in whom the changes tended to be more severe) On comparison with other criteria of rheumatoid arthritis in the population sample, it was found that the cervical changes were significantly associated with positive sheep-cell agglutination tests and also with radiological changes of rheumatoid arthritis in the hands or feet, but only poorly correlated with rheumatoid arthritis as diagnosed clinically Both clinical rheumatoid arthritis and radiological changes of the disease in the hands or feet, however, showed a very significant association with positive sheep-cell tests

These findings suggested that in the general population the disease may be encountered in a form in which the spine was mainly or exclusively involved but which was not diagnosed clinically as rheumatoid arthritis in the absence of changes of rheumatoid arthritis in peripheral joints and that this form of the disease may be important in studies of the prevalence of rheumatoid arthritis in populations since it may account for some apparently "false" positive results in the sheep-cell agglutination test. In clinical practice, rheumatoid involvement of the cervical spine was important both on account of the associated pain, which may be severe, and the resultant mechanical instability, which may lead to severe cord damage.

Reviews of Books

Cortisone Therapy

J H. GLYN, M.D M.R.C.P., D.PHYS.MED., consultant in physical medicine, Prince of Wales and Tottenham Group of Hospitals
London Heinemann. 1957 Pp 162. 21s

THE experience of eight years has not sufficed to define clearly all the indications for the use of cortisone and all its limitations That controversy has not yet been stilled is no reason for denying to those who seek it a convenient source of guidance on the present position of treatment with the hormone or its related steroids Such guidance Dr Glyn has now concisely supplied, in a form that will be widely appreciated.

He has had much experience of cortisone in the treatment of rheumatic disorders and his views are very personal. As Lord Cohen of Birkenhead remarks in a foreword, not all will approve unreservedly of the opinions expressed, but in general these opinions are unlikely to lead the practising clinician far astray In rheumatoid arthritis, Dr Glyn's view is that steroids are strongly indicated in some 10% of cases His reaction to the results of controlled trials, comparing cortisone and aspirin in the treatment of rheumatoid arthritis, is that they served to curb overenthusiasm for cortisone without necessarily casting serious doubts on the wisdom of its use under particular circumstances He holds that individual patients may benefit more from cortisone than from other forms of treatment, and that statistically controlled trials may fail to establish this he tends to accept or reject the evidence of controlled experiment according to whether or not it agrees with his own impressions Thus in discussing whether cortisone is a useful adjunct to manipulation, he is reluctant to accept the negative results of a trial and elsewhere uncontrolled clinical data bearing on the role of steroids in precipitating arteritis are rejected and statistical corroboration demanded. The reader is left in little doubt, however, that opinion on many topics has not yet crystallised, and the practical advice on administration and precautions is very sound. Dr Glyn believes that the dangers of steroid therapy have been overemphasised but he gives a full account of its undesirable effects

In an appendix by Dr J G Bearn, some good anatomical guidance is given on the technique of intra-articular and other forms of local-injection treatment with steroids The book concludes with some suggestions for assessing and recording clinical progress and with a short bibliography

Current Surgical Management

Editors JOHN H MULHOLLAND, M.D., professor of surgery, New York University School of Medicine, EDWIN H. ELLISON, M.D., associate professor of surgery, Ohio State College of Medicine, STANLEY R. FRIESEN, M.D., associate professor of surgery, pathology, and oncology, University of Kansas School of Medicine. Philadelphia and London W B Saunders 1957 Pp 494 70s

WHAT an exciting book this might have been! The editors invited some of the leading exponents of opposing schools of surgical thought not only to air their views but to thrash out their problems in open debate The subjects ranged from the management of acute cholecystitis to perforating wounds of the heart, and they included such controversial topics as the treatment of peptic ulcer regional ileitis, cancer of the breast, cancer of the thyroid, pancreatitis, and burns The list of contributors guaranteed that the opinions expressed, however extreme, would merit a few moments' thought at least

If the hopes thus generated by the contents page had been less high, there might have been no disappointment. Some of the sections are indeed admirable. Blakemore, Garrott Allen, Child, Robert Moore, and A C Singleton on portal hypertension and bleeding oesophageal varices provide the most lavish fare, but there are others almost equally good As a whole, however, the book falls short of expectation. As the editors themselves remark, "what appears on the surface as marked differences of opinion is (often) not so marked when more deeply probed" and much that is stale might have

Medical Societies

THE HEBERDEN SOCIETY

THE annual general meeting of the society was held on Dec 13 and 14 There follow summaries of some of the papers read at the meeting

Phenylbutazone in Rheumatic Fever

Dr G WILL described the treatment with phenylbutazone of 32 cases (19 males and 13 females) of acute rheumatic fever, all fulfilling the modified Duckett Jones criteria 17 patients were of 16 years of age or under, and in 21 it was the first known attack of rheumatic fever 11 patients had been initially treated unsuccessfully with aspirin The maximum daily dosage of phenylbutazone was 600 mg This was given for the first few days and was followed by 400 mg daily for two weeks, then 200 mg daily for a further two weeks

In every case there was a rapid response to treatment Joint pain and swelling were relieved within twenty-four to forty-eight hours and fever and tachycardia settled in three to five days The sedimentation-rate fell steadily to normal levels in all cases it had fallen to 15 mm (Westergren) in one hour or below by the end of the fifth week of treatment In 2 cases premature cessation of treatment was followed by relapse, with subsequent control on resuming treatment with phenylbutazone There was only one serious toxic episode in the series, a melæna 3 patients had mild epistaxis

Pathology of the Rheumatoid Cervical Spine

Dr J BALL said that a characteristic feature of the intervertebral discs of the cervical spine was the presence of a synovial joint—the neurocentral joint—adjacent to their lateral borders *In a postmortem study of 20 cervical spines from* typical cases of rheumatoid arthritis (not selected on clinical or radiological grounds) neurocentral arthritis was found in all but 1 of the 18 cases in which this area was examined, apophyseal joints were involved in 19, in neither was there a preferred site of involvement Disc lesions were often encountered, mainly in the posterolateral and anterolateral parts of the annulus and also along the disc-bone border in these regions Serial sections indicated that the lesions were extensions of pannus arising in the roof or the anterior or posterior recesses of the neurocentral joint In the affected area the annulus was replaced by a granulation tissue whose appearance varied according to the degree of maturation, the occurrence of bone in the posterolateral part of the annulus may represent a quiescent stage of a rheumatoid erosion and may be found in association with bony ankylosis of the corresponding neurocentral joint

Atlanto-axial dislocation was found in 3 cases Dislocation at the first, second, or third disc occurred in 5, and in each instance there was associated erosion of the disc annulus posteriorly, anteriorly or in both sites Appreciable disc erosion was not necessarily accompanied by subluxation, occasionally this could be accounted for by ankylosis of the corresponding apophyseal or neurocentral joint In the single case in which dislocation was severe enough to cause compression of the cord, it was noted that some degree of fixation was present above and below the level of dislocation, due mainly to ankylosis of apophyseal joints

The disc lesions found in the rheumatoid cases were not encountered in the cervical spines of 12 elderly subjects considered not to have suffered from polyarthritis It was also noted that whereas in the control cases disc narrowing and osteophytosis were predominantly located at the fourth and fifth discs, in the rheumatoid cases disc narrowing when present showed no such predilection for the lower discs and was often unaccompanied by conspicuous osteophytosis

Heart lesions in Rheumatoid Disease

Dr B CRUICKSHANK remarked that previous workers had described a variety of non-specific cardiac lesions in patients suffering from rheumatoid disease, and the occurrence of rheumatoid granulomata in the heart was well-recognised, though rare Most of the non-specific lesions had been regarded as rheumatic The whole picture was complicated by the inclusion of examples of ankylosing spondylitis in several of the previous series

Heart lesions, other than those attributable to some other disease, had been studied in 100 patients suffering from rheumatoid disease Rheumatoid granulomata were found in the mitral and aortic rings and cusps in 5 patients and in the myocardium in 1 of these Active rheumatic heart disease was seen once and healed rheumatic endocarditis in 5 patients, in 2 of whom no histological examination was made Non specific chronic endocarditis was seen in 9 patients Although the macroscopic appearances suggested rheumatic endocarditis, microscopic examination failed to reveal characteristic lesions of that disease In 4 of these patients the inflammation was active and diffuse, with many of the features found in rheumatoid lesions elsewhere in the body, though necrosis was absent These were regarded as further examples of rheumatoid endocarditis The other cardiac lesions encountered were myocarditis (10 patients), arteritis (20), and pericarditis (15), all of which were commoner in patients admitted to hospital for treatment of rheumatoid disease than in those admitted for treatment of intercurrent disease In many of these patients tissues other than the joints were extensively involved

The incidence of rheumatic heart-disease was no higher than in unselected necropsy series Rheumatic fever, it was concluded, played no significant part in causing the cardiac lesions of rheumatoid disease, and many of these lesions were part of the rheumatoid process itself

Ulcerative Colitis and Arthritis

Dr B M ANSELL and Dr E G L BYWATERS reviewed all cases of definite ulcerative colitis attending Hammersmith Hospital and the Canadian Red Cross Hospital, Taplow, over the past ten to eleven years The overall incidence of arthritis appeared to be 15% 37 cases of arthritis with proved ulcerative colitis from this source and from patients seen at the Central Middlesex and West Middlesex Hospitals have been studied very closely The knee- and ankle-joints were the ones most often involved and, in contrast to rheumatoid arthritis, hand and tarsal joints were much less often affected There was a relatively high incidence of sacroiliac involvement, and of particular value diagnostically was the swelling of the proximal and distal interphalangeal joints of the toes

In most cases the arthritis was that of a recurrent mild synovitis, gross changes being found in only 4 cases, of which only 2 were typical of rheumatoid arthritis with nodule formation and a positive direct agglutination test (D A T) 29 patients had the Rose test repeated on a number of occasions 25 were persistently negative, the 2 already mentioned were persistently positive, and 2 others positive on one occasion only 8 of the 37 cases had erythema nodosum and this might occur early in the course of their disease or *during an exacerbation* In 7 of these the arthritis was present at the time of the erythema nodosum, and 1 of these patients also had pericarditis

The frequency of the arthritis, its course and pattern, its joint distribution, its frequent association with erythema nodosum, and the negative D A T suggested that it was a separate arthritis from rheumatoid arthritis, due either to the factor that produces the gut lesion or secondary to that lesion, or if it was rheumatoid arthritis it had been considerably modified by the presence of ulcerative colitis

Antinuclear Serum Factor in Connective-tissue Disease

Dr E J HOLBOROW and Dr D M WEIR had examined sera from 100 cases of connective-tissue diseases by the fluorescein-conjugated antiglobulin test for the presence of the antinuclear factor previously described [1] in disseminated lupus erythema-

Sex Reversal

By the "sex" of an individual we may nowadays mean one of several different things—such as the genetic sex, determined cytologically, the gonadal sex, determined with certainty only histologically, the anatomical sex, determined by inspection of the genitalia, the hormonal sex, determined biochemically, the social sex, determined by upbringing, and the psychological sex, determined by behaviour In most of us, of course, all the "sexes" agree but results at any level may be equivocal, and when unequivocal they may disagree with equally unequivocal results at any other level Such discrepancies are only moderately rare, and it begins to seem probable that every possible permutation of discrepancies can occur The older classifications of "pseudohermaphroditism" and the like are no longer sufficient, and there is urgent need of a new terminology And it is, for instance, not really justifiable to limit the term "sex reversal" as Dr Ashley and Dr Jones do in their paper on p 74 to simple discrepancy between genetic sex and all the other "sexes" at the opposite end of the scale transvestitism is equally a sex reversal

Nevertheless, if only because of the light thrown on them simultaneously by nuclear sexing techniques, it is worth considering together briefly the known varieties of extreme discrepancy between genetic sex and apparent sex There are perhaps four chromatin-negative Turner's syndrome (genetic male, gonad neutral, otherwise feminoid), chromatin-positive Klinefelter's syndrome (genetic female, gonad male, otherwise masculinoid), "testicular feminisation" (genetic male, gonad male, otherwise feminoid), and Ashley and Jones' case (genetic male, gonad female, otherwise feminoid) The first two are now very well known, and nuclear sexing, especially by the oral-mucosal smear technique, has so facilitated their recognition that they are becoming almost common [1–7], but the two latter are less familiar

When reported at a meeting last summer, Ashley and Jones' case was in fact the first certain example of its kind to be described there are a few possible earlier cases, but in none is information complete enough for certainty The infant was by all ordinary criteria female there were some minor pseudohermaphroditic features (an enlarged clitoris and a double urethra), but the vagina, uterus, tubes, and ovaries were clearly female, and the ovary had a full complement of ova The only discrepancy is the male nuclear sex In a sense, this is a mirror image of chromatin-positive Klinefelter's syndrome—male gonad and habitus with female nuclei in the one, female gonad and habitus with male nuclei in the other—though it would be unwise to push that analogy too far There will almost certainly be a tendency to regard this as a mere variant of Turner's syndrome Admittedly there is a variety of Turner's syndrome [8 9] in which virilisation occurs to a minor degree, with clitoral enlargement (one can probably blame activity of the Leydig-like hilus cells [10] for this), and the mild pseudohermaphroditic features of Ashley and Jones' case could probably be explained in this way There are also cases of Turner's syndrome in which the ovarian vestige contains a few follicles,[3] and it is just possible that these represent the adult state of Ashley and Jones' case But on the whole it seems better to regard this for the present as a new and separate entity Apart from anything else, acceptance of it as a variant of Turner's syndrome could overturn the whole satisfactory edifice of explanation of that syndrome as a kind of intrauterine castration, for this patient is certainly not a castrate Some distinct mechanism must have been operative, and one can do no more than speculate on its nature

A minor but most interesting point emerges from the case. The nuclear sex, tested at several points, is male, but the polymorphs are female Similar discrepancies have been noted in Klinefelter's syndrome in the opposite direction [11] One may add to this the fact that the characteristic drumstick structures seen in polymorphs in blood-films from females are seen in several animal species—notably the rabbit—in which the sex chromatin cannot be seen in tissue nuclei It is increasingly apparent that Davidson and Smith's polymorph drumsticks are not simply modified sex-chromatin bodies [12] The question now arises, what are they?—a fascinating new problem. Meanwhile, it is clearly no longer sufficient to rely on polymorph sexing in cases of possible sex reversal

The fourth of the sex reversals deserves to be better known, and certainly better considered than in our last brief and partly inaccurate mention of it [13] It is a very well defined syndrome with a considerable literature, which has, we fancy, missed the public eye chiefly for lack of a sufficiently exact name "Male pseudohermaphroditism", variously qualified, is its usual label, but that is too vague and all-inclusive a term Morris,[14] though he did not discover or claim to discover it (he collected 72 reported cases), suggested the term "testicular feminisation", a name at once compact, evocative, and precise, and one which we think (pace Dr Swyer [15]) might well be adopted Essentially the condition consists in the combination of male nuclear sex and testes with a fully feminine external anatomy and endocrine status [14 16 17] (The nuclear sex has of course been determined only in recent cases, but there seems to be no doubt that it is constantly male [18 19] an error in these columns [13] was derived from a misreading of Danon and Sachs' paper [20]) Though many cases present themselves

20 Danon M Sachs, L *Lancet*, 1957, ii, 20

early in life with inguinal herniæ [21]—operation on which results in discovery of the testis in or near the sac—the most striking cases are those found later in life, after they have undergone what seems to be a normal puberty apart from amenorrhœa They then appear, in build, external genital anatomy, breast development, and social attitudes, to be normal women, but they sometimes have moderately eunuchoid proportions, and usually the body hair is deficient Gynæcological examination reveals a blind vagina and absence of the uterus laparotomy shows gonads which may closely imitate ovaries in external appearance and site (though they may descend to the inguinal canal and then give rise to herniæ) but in *histology* are clearly testes They are not normal testes, but then they are not at the normal site of testes, and their abnormalities are, at least chiefly, those constantly seen in cryptorchidism In some cases at any rate they have shown some degree of spermatogenesis,[22] and they have the increased liability to tumour of all abdominal testes It is beyond doubt that these gonads are testes but it is equally beyond doubt that they secrete female hormones, for their removal produces menopausal symptoms and breast atrophy [23]

Often if not always this condition is hereditary, and some remarkable pedigrees are known [22] Though the exact mechanism of inheritance has been [22] and is [20] [24] a matter of dispute, it is evidently transmitted through the female only in affected sibships all, or nearly all, the males become testicular-feminoids, and all the females are normally fertile, half of them being carriers Unless one restricts definition very closely to cases with the completest feminisation, this variety of sex reversal is not very rare and there is a very real need—greater perhaps even than with other varieties—that the doctors who handle such a case in the first place should understand something of its nature (DIEKE [25] gives a vivid illustration of the dangers of vacillation) The discovery of testes must not be made a signal for drastic attempts to change the established sex of the patient nor should the testes be removed—at any rate before the age of 20—for they provide the hormones essential for adolescent development There is a case for their removal later in life, as a potential source of tumours in this respect, and this alone, we can treat them as ordinary cryptorchid testes Quite apart from such practical issues, these cases are of very great interest, and some part of the light which has beaten recently on other types of sex reversal might well be spread to include this variety Guidance would be especially welcome on the prognosis of feminoid children found to have testes early in life may we always assume that these anomalous gonads will produce feminising hormones at puberty, or is there a risk of virilisation, and if so, are there any criteria by which one can recognise the cases concerned? And is it true [21] that these patients not only do not produce their own androgens, but are resistant to therapeutic doses of synthetic androgens?

DR SWYER, who very properly pointed out the errors in our early editorial,[13] took us to task also [15] for saying *that no combination of hormones has yet made an XY* breast secrete milk The example he gives in refutation is a poor one, for Foss [26] produced only a drop of "*colostrum*" from his transvestite—hardly milk He might better have quoted the engorgement with milk produced in male rat breasts by multiple hormone treatment [27] But even that milk did not reach the exterior—it was only halfway secreted There are still *some* limits to what hormones can do to a male breast

Occupation and Compensation

IN the course of a chronic disease many circumstances tend to produce neurosis , and when the disease is occupational, permanent in its effects, sometimes difficult to diagnose, and responsible for a disability often hard to assess, these circumstances are particularly potent Following a discussion on the working of the National Insurance (Industrial Injuries) Act at a recent course on industrial pulmonary diseases at Hammersmith Hospital, correspondents in our columns have emphasised how administrative difficulties influence decisions about benefit claims for pneumoconiosis Critics have pointed to the anomaly where one man severely disabled by chronic pulmonary disease has his claim rejected and another with little functional impairment obtains benefit, to lack of uniformity in the application of the Act in different localities, to overmuch importance attached to X-ray appearances, to failure to use respiratory-function tests, and to the rejection of some applicants without clinical examination after initial scrutiny of chest X-ray films On the other hand, it has been submitted that, though discrepancies arise, the present arrangement works very well within the framework of the law, and that it would be hard to find a better

It is not to be disputed that bronchitis and emphysema are commoner among workers in many dusty occupations than among the general population , and the inference is that some of the increase is occupational On the other hand, bronchitis and emphysema are common in city-dwellers with no occupational exposure to dust or fumes Claimants whose X-ray films show the characteristic changes associated with pneumoconiosis can usually be accepted without question as having occupational disease, but doubt exists in the cases without typical radiological findings As the law stands, bronchitis and emphysema are not pneumoconiosis and so are not compensable Whatever part the X-ray examination may be held to play in assessing the stage of the disease, it is undoubtedly a necessary step in diagnosis The dilemma of the administrators is that the restriction of benefit to claimants with pneumoconiosis as at present defined by law means the rejection of some men and women with chronic pulmonary disease which *may* be of occupational origin, while widening the scope of the scheme would admit to benefit many non-occupational cases

The past twenty years have seen a very considerable widening of the scope of the original Workmen's Compensation Act in regard to industrial pulmonary disease Nevertheless criticisms do not seem to have diminished, and the sense of frustration experienced by rejected claimants, their relatives and workmates, and their doctors, when the disability is strongly believed to be occupational, is hard to dispel Moreover, there is misunderstanding of the functions and the powers of the pneumoconiosis medical panels and of the reasons for rejecting particular claims Further widening of the scope of the Act will do nothing to remove the causes of dispute, but merely extend the limits of controversy The main cause of contention is the considerable difference between the rates of benefit payable in industrial and non-industrial diseases It becomes an important issue for the workman to establish that his disease is occupational in origin It is often impossible to do this beyond doubt it may be easy to exclude an occupational cause if there has been no exposure to dust or fumes, but in a group of workmen occupationally exposed what doctor would undertake to distinguish the occupational from the non-occupational cases of bronchitis and emphysema in the absence of characteristic X-ray findings? The same problem arises in connection with other industrial diseases—notably perhaps, dermatitis—where the difficulty of establishing the precise cause of the disease, and the ensuing litigation, may contribute greatly to the anxiety, depression, and even demoralisation of the sufferer

What is the basis for compensation schemes? Are there valid reasons for paying a higher rate of benefit for an injury or disease arising in the course of employment than for one contracted in the domestic or public environment—for a factory accident than for a street accident, for pneumonia due to accidental exposure to nitrous fumes at work than for pneumonia complicating influenza, for pulmonary disability due to industrial dust than for that contracted through living in overcrowded conditions? Doctors who worked in child-welfare clinics in the 1930s will remember the many infants who suffered from repeated, almost continuous, bronchitis Are they now among the chronic bronchitics of the community, some of them workers in mines or foundries and blaming dust for their condition? Why should a man who chooses to work in an industry with a known dust hazard qualify for a higher rate of benefit if he contracts pneumoconiosis than the equally disabled chronic bronchitic who had no control over the environment which caused his condition? Would not the paying of equal rates of benefit be reasonable?

The widespread feeling of dissatisfaction with the Industrial Injuries Benefit Schemes undoubtedly has its origin in the different rates of benefit payable for industrial and non-industrial illness During the discussion at Hammersmith Hospital Dr A T Doig called attention to the need for examining the position and equating the two rates, and Dr Gilson and Dr Hugh-Jones and their colleagues suggested similar action in their letter of Dec 7

> "Two courses are possible The first is to abandon the rigid attribution requirement [i e, that the disease shall be attributable to the occupation in the individual case] and, in occupations where epidemiological studies have shown an increase in the prevalence of the common diseases, to compensate any disabled man as if all his disability was due to occupation This would remove the injustices which your correspondents claim to exist, but only at the expense of introducing new ones The second requires a fundamental change in approach—namely, to make provision under the National Health Insurance Scheme for adequate benefits for the disabled irrespective of how the disablement has been caused If this were done, epidemiological studies would return to their primary objective—prevention"

The opener of the debate in our columns, Dr Norman Macdonald, also supports this second course in his closing letter of Dec 28 He returns to his early suggestion, which seems to have been lost sight of in some of the succeeding letters, that a fully independent committee or commission should be set up to review the position As he says, the problem has been in the past, and still is, altogether too vexatious and absorbent of time and mental energy, which could be better devoted to preventive measures Its solution would bring a sense of freedom and relief to all concerned

Annotations

GETTING OVER OPERATIONS

As Dr R M Davies told the Section of Anæsthetics of the Royal Society of Medicine last Friday, a patient's need of skill and care following surgery is most acute as he leaves the operating-theatre, for he is then suffering not only from his disease but also from the effects of operative trauma and the residua of anæsthesia Yet at precisely this moment he is likely to be sent on a long journey to a ward, which can in itself be dangerous The particular kind of skill and care he needs cannot be provided consistently throughout the surgical wards, and in Dr Davies' opinion it is best concentrated in a single ward where all patients should stay for a while immediately after operation This ward should be very near the theatre, so that long journeys are avoided and the surgeon and anæsthetist can get quickly to the patient if necessary

Mr J R Belcher, and other speakers who followed him, were generally in agreement with these principles, but Mr Belcher thought that more emphasis should be placed on recovery before the patient leaves the theatre No patient, he thought, should leave the theatre till he is breathing well and reasonably conscious, and warm if he has had hypothermia In the discussion, nobody spoke against recovery wards or disputed Dr Davies' contention that they save lives, as his experience with 33,000 patients at East Grinstead shows Some thought that not every patient should go through a recovery ward, but, as Dr Davies said, the anæsthetist cannot tell in advance which patients are going to be in trouble As regards the ideal size and organisation of such a ward, most speakers agreed that this must vary with the type of hospital Patients who have metabolic difficulties (e g, after hypophysectomy) or have had unusual operations (e g, involving a cardiopulmonary bypass) may need special provision Skilled nursing is essential and a day-

and-night service highly desirable, especially since emergency patients are the ones who stand in most need of recovery rooms The ward, it was felt, should probably be in the charge of an anæsthetist, and a resident in anæsthetics act as the house-physician The nurse in charge should have the rank of sister and should remain in the ward for several months in some hospitals with recovery wards the student nurses spend short periods there, which gives them experience they would otherwise miss because the patients are no longer treated in general wards, but in others the ward is staffed by part-time qualified nurses from outside the hospital In a hospital which has many scattered theatres, a choice must be made between concentration of skill and apparatus, on one hand, and proximity of the recovery ward to the theatre on the other Most speakers favoured proximity, if a choice must be made, though the answer might be different if nurses were scarce

Prof E A Pask felt sorry for the patient who had been in the general ward long enough to get used to the staff, and awoke after operation in strange surroundings Other speakers had found that patients do not mind this, if they have been told beforehand, and indeed welcome the solitude in which they awake Some thought that the patient should spend the day before operation in the recovery ward, this would be hard on the patient at the bottom of the operating-list, who will see his predecessors return laden with drips and tubes and perhaps vomiting, but would avoid much of the nocturnal turmoil of general wards where emergency patients are admitted Perhaps the ideal would be to admit night emergency patients to the recovery ward before operation, but other patients only after operation Patients should stay in the recovery ward for as long as it will benefit them—which may be for minutes or for days

Dr G F Rawdon Smith feared lest the development of recovery wards should lead to yet another specialty Professor Pask replied that this warning came too late, for in France there is already the *réanimateur*, and doubtless he will come to Britain with the Common Market

KURU

THE discovery of a new disease has the same fascination as the identification of a new element or a new planet Four years ago Patrol-Officer J R MacArthur reported a strange endemic disorder in a newly explored area south of Mount Michael in the Eastern Highlands of Australian New Guinea He wrote " I observed a small girl sitting down beside a fire She was shivering violently and her head was jerking spasmodically from side to side I was told that she was a victim of sorcery " This trembling disease (it was called *kuru*), with its preference for females and its fatal outcome, had been known to the Fore tribe, who now number about 11,000, as their special curse for at least twenty years, and it had been observed by Berndt in 1952 and 1953 in them and adjoining peoples Extensive investigations were undertaken by Zigas and Gajdusek, who with commendable enterprise established a kuru research centre at the Okapa patrol post Their first reports [1] [2] record their findings in 150 cases

The disease, which has been observed at ages from 5 to " over 40 ", is confined to the Fore people and to members of contiguous tribes intermarrying with them It is, for instance, unknown in the neighbouring Kukukukus who have no marriage contacts with them and who are cut off by the formidable barrier of the Lamari river, but it has arisen in several members of a substantial party of Ingarias who migrated from the western slopes of Mount Michael, later to intermarry with the Fores The disease has also been reported, however, in a few women from communities with a low kuru incidence after entry into a kuru region, and this fact has to be satisfactorily explained before this can be accepted as a genetically determined disease The male/female ratio is 1/5 42, and in 23% of the observed cases the patient's age was less than 15 About 1% of the total population is at present affected, but in certain localities this figure may reach 10%, indeed, kuru sometimes accounts for half the deaths in a community

The onset is insidious, with ataxia ("loose knees"), but about a third of the patients have prodromal symptoms (not, so far, observed)—knee pains, headaches, malaise, fever, cough, and coryza, in order of frequency, but never an acute illness As the ataxia progresses a distinctive tremor appears, irregular but fine, involving the head, trunk, and limbs, it is aggravated by excitement, fatigue, or attempts at voluntary movement It tends to subside during relaxation and disappears during sleep In the second and third months the tremors coarsen and interfere with work and sleep, but the state of nutrition remains good Choreiform jerks with wild athetotic movements may appear, especially when the patient tries to stand Emotional behaviour may be prominent, paroxysmal hilarity alternating with moods of depression By this stage the patient has to use a stick for support while attempting her daily work, but soon she is forced to sit and has to be carried to the pig feasts and other tribal ceremonies A progressive dysarthria sets in and often a convergent strabismus, a flexed posture, and a parkinsonian facies Soon she is confined indoors, mute and doubly incontinent, and rapidly succumbs to starvation, decubitus, or some intercurrent infection

The course of this disorder is from three months to two years or more, with an average of six to nine months Although it is almost always steadily progressive, in 2 cases remissions have been observed (two in 1 case) followed by relapses, 2 presumed instances of the disease were noted to appear and remit with the menstrual cycle Kuru, which is apyrexial throughout, does not interfere with pregnancy and there are no physical signs other than those referable to the central nervous system The fundus oculi is normal and the pyramidal tracts are not involved The cerebrospinal fluid has revealed no abnormality except an occasional positive Lange curve Increases in the β-globulin and sometimes the α-globulin in the serum, when observed, have had to be discounted because they may be noted in New Guinea highlanders unaffected by kuru Immunological, therapeutic, and chemical studies, including some on copper metabolism, are so far negative

Pathological findings are confined to the nervous system, where preliminary observations point to a widespread neuronal degeneration with neuronophagia, the parts most affected being the cerebellum and extrapyramidal system and, to a lesser extent, the anterior horn cells, the inferior olives, thalamus, and pontine nuclei

The Fore people live in a heavily forested terrain, covered with kunai grass, at an altitude of 5000–7000 feet No toxic substance in the diet, water, soil, or body paints, or anything else in the environment has been found to account for the condition. In fact the evidence is so far in favour of some genetically determined degeneration of the central nervous system, and this is supported by the facts that kuru has been known to develop in several siblings at the same age and that the disease may show the phenomenon of anticipation. A congenital tremor has been seen in two Fore natives and occasional instances of parkinsonism are known in adjacent territories, but these conditions are easily distinguished from kuru. Further information on this striking disease will be awaited with interest, for it may well serve to throw welcome light on unsolved problems of neuropathology.

MEASUREMENT OF BLOOD-PRESSURE IN INFANCY

ALTHOUGH determination of the blood-pressure is not always regarded as a part of the routine examination of infants and children,[1 2] more conditions are now being recognised in which a dependable method of estimation is necessary.[3] For clinical purposes, one of the usual cuff methods (using auscultation, palpation, or oscillometry) can generally be applied, even to newborn babies, and Holland and Young[4] succeeded in measuring the systolic pressure in premature infants weighing as little as 4 lb by palpation of the brachial artery. The estimation must be made while the infant is quiet, which may mean waiting until he is asleep, or giving a sedative. By comparing the results with those obtained by direct intra-arterial measurement, Robinow et al.[5] showed that if a cuff of suitable width is used (2.5 cm. for newborn and 5 cm. for older babies) sufficiently accurate readings of the systolic pressure can be obtained by ordinary clinical methods, though there are errors in the diastolic readings because of difficulty in hearing the Korotkow sounds. The use of an amplifying stethoscope may make auscultatory determination both easier and more accurate. Where the conventional methods are unsuccessful, the "flush" technique of Gaertner[6] may be used. It depends on the production of reactive hyperæmia by deflating a cuff from a pressure of 300 mm. Hg, at a rate of about 5 mm. per second, on a limb made relatively bloodless distally by compression with an Esmarch or similar bandage. The limb is held at heart level and watched in a good light, and the pressure at which the first flush appears is noted. Since this method was first used in infants by Cappe and Pallin[7] and by Goldring and Wohltmann,[8] a number of reports on it have appeared,[9–12] and it has become an established clinical method.[13]

Average figures for normal brachial pressures in newborn babies are 80/46 mm. Hg, for babies aged six months 89/60, and at one year 96/66,[14] but the flush method gives values 10–20 mm. lower than systolic pressures obtained by palpation, auscultation, or direct measurement—i.e., it gives approximately mean pressures. The arm pressure is normally given as a few mm. higher than the leg by this method,[8] but in 8 cases of coarctation of the aorta the difference was 36–88 mm.[12] The flush method takes longer than conventional methods of sphygmomanometry, and is more likely to make babies cry; but even if they do, according to Forfar and Kibel,[10] an error of only 7–10% is introduced. Schaffer[15] wrote "the flush method is simple but coarse and unreliable," and it is undoubtedly inferior to auscultation when the sounds can be well heard. It is useful, however, for babies whose brachial pulses cannot be felt, and for femoral blood-pressure estimation in suspected coarctation of the aorta.

F.A.O.

A SMALL book[16] sets out in simple language the problems that the Food and Agriculture Organisation of the United Nations has faced in the first twelve years of its life. These problems still exist, for, as the director-general, R. B. Sen, says in his foreword, "there are today millions of hungry people, there are unused resources, maladjustments of distribution, depressed rural population." Nevertheless, the record is heartening, for F.A.O. has proved a good means of spreading knowledge in underdeveloped countries. The greatest difficulty in its way has been that of getting the necessary cooperation between Governments, especially in economic matters: too narrow a nationalism remains an important hindrance to scientific development. But it is significant that the Governments of the various countries of North Africa have never been so united—or so effective—as when serving as members of the Desert Locust Control Committee, sponsored by F.A.O. National political wisdom may grow on a diet of international scientific knowledge.

NEW YEAR HONOURS

SIR Harry Platt was knighted six years before he became president of the Royal College of Surgeons, and the baronetcy now bestowed on him recognises his three years' tenure of that great and strenuous office, as well as the value, in all his capacities, of his vigour and freshness of mind. The particular reason for Sir Stewart Duke-Elder's promotion to be a knight grand cross of the Victorian Order is presumably his services to the Royal Family, but these are of course only one manifestation of his remarkable services, through ophthalmology, to medicine. Of the new knighthoods, two, in the Order of the British Empire, are conferred on the recently appointed heads of the medical departments of the Royal Navy and the Royal Air Force, Rear-Admiral R. C. May and Air Marshal P. B. Lee Potter. Three of the knights bachelor work in Australasia (Dr. H. R. R. Grieve, Mr. W. G. D. Upjohn, and Dr. Ralph Whishaw) and three in Great Britain. Of Professor Krebs, of Oxford, Nobel prizewinner of 1953 and discoverer of the citric-acid cycle, it has been said that as a leader and teacher he has instilled the element of genius that turns possibilities into realities. Dr. Kenneth Cowan has retained and increased the confidence of his colleagues by his understanding work as chief medical officer of the Department of Health for Scotland. Dr. Bentley Purchase's championship of the difficult office of coroner, as well as his outstanding labours in it, deserve the honour they now receive. These are only the first names of a list which brings forward, for public thanks, much notable work—some of it widely known but much of it done in places where only a few colleagues can be aware of its quality.

Points of View

A PLASTIC APPROACH TO SURGERY

CHARLES HEANLEY
T D, M A, M B Cantab, F R C S, M R C P
CONSULTANT PLASTIC SURGEON, THE LONDON HOSPITAL, E 1

THERE is no such thing as a "lucky" surgeon—"the wind and the waves are on the side of the ablest navigator" To be lucky is to know the rules and to know when to break them

The first rule is that diagnosis should precede treatment, and to disregard this rule is "worse than a crime, it is a mistake" The word "diagnosis" is merely a verbal symbol to represent a living and changing phenomenon, diagnosis in its fullest sense is an understanding of the pathological process present The making of a diagnosis is a continuous process which does not cease with the start of the operation, but should always be one step ahead of the treatment It is fatal to cling to an incorrect diagnosis, so, having made a diagnosis, do not stick to it A plastic outlook is essential Each case should be treated on its own merits, since no two cases are the same The man with a rigid method and technique is dangerous if he says that something is always so, he is either teaching or no surgeon Since pathological processes change, what was a correct diagnosis at one time may be wrong later One should start an operation with a working diagnosis, together with a clear conception of the known facts and an open mind

One learns quickly from one's own mistakes, sometimes too quickly It is nicer to learn from the mistakes of others However, it is essential to be able to recognise a mistake, and it may be hard to realise that the result might have been better Inquisitiveness is an essential attribute of a good surgeon, because inquisitiveness leads to an increase of knowledge, and to know all about a *condition is to know its complications, and thus avoid them*

Do not ignore the opinion of the uninstructed, for rude minds sometimes contain pearls of wisdom, and discussion is always helpful, because what is dark when unspoken may become clear when discussed

Although the diagnosis is correct, it may be difficult to decide on the treatment, because this so much depends on the prognosis The knowledge of the prognosis of a disease and the assessment of the prognosis in the particular case is essential in deciding the treatment, especially in carcinoma

So often the problem *is not how to do the operation,* but what operation to do, since it is the duty of the surgeon to prolong living in comfort, rather than to prolong the discomfort of dying A clear conception of why one is operating at all, and why the particular operation has been decided upon, should always be kept in mind

You should not do today in an ill patient what can be done tomorrow or later in a fit patient Emergency operations should be avoided, if possible the acute abdomen, for instance, is a Pandora's box of mischief To an already ill patient do not add the insult of a big operation, *he needs a life-saving operation, and no more* Do not try to paint the lily, for a live weed is better than a dead lily

* * *

The gentle handling of tissues is essential, this rule must not be broken Avoid lethal surgery, whether it is a cell or the patient that dies The more dead or dying cells left in an operation site, the slower the recovery The heavy-handed surgeon who mauls tissues, often with the aid of fierce instruments and retractors, is the one who complicates already elaborate techniques in a vain attempt to reduce the incidence of postoperative sepsis

There must be no tension, either in the surgeon or in the tissues Healing is quickest when the tissues lie adjacent to one another without tension or compression Both these states, which are associated with tight stitching, upset the blood-supply to the healing edge Sutures should *be inserted in such a way that the blood-vessels in the loop* of the stitch are not compressed, either at the time of stitching or later when the tissues swell from postoperative œdema otherwise more trauma is caused, with more œdema and more compression Whereas a ligature is for *hæmostasis, a suture is to approximate tissues until they* heal, and a stitch that is inserted to perform both these functions is essentially bad The stitch that sutures the transverse mesocolon to the stomach in the posterior Polya gastrectomy should be tied so loosely that even if the middle colic vessels are contained in its loop, they are not obstructed The stitch that sews the peritoneal layer but inadvertently pierces the gut lumen will not slough out Often the leakage of intestinal contents results from a stitch obliterating the blood-supply to the suture line I remember a surgeon who, his muscles bulging as he tied his sutures, said "I can never understand why my colporrhaphies break down—I tie my stitches tight enough"

Each stitch must be inserted and tied as if it were the most important one Since a successful operation depends on its weakest stitch, each one should have meticulous care *As is seen in skin suture, a badly placed stitch* cannot be corrected by any number of rightly placed stitches, so it should be removed at once If the stitches are loose and soon removed, only the incision will be visible, and not the stitch marks But stitches can be removed early only if there is no tension and a good blood-supply On the face, for instance, stitches can be removed in three days, but where the blood-supply *is bad, as on* the back, they may have to be left in for fourteen days

By your scars will you be judged—the patient honours the surgeon if the scar is neat, for if the internal malady is cured, what is left save the scar by which to judge the result? *A neat suture line may cover a multitude of sins* Incisions should be made in the direction of Lange's lines, *which for the most part lie in the flexion creases If a circle* is drawn on the skin, and the circle of tissue is removed, the resultant bare area is larger than the area removed, and is oval in shape, showing that tension, and unequal tension, exists in the skin Therefore, if the incision is made at *right angles to direction of the least tension* a good scar results, if it is made in another direction there may be a contracture

"I shall excise the scar, the whole scar, and nothing but the scar, so help me Hippocrates", is the initiate oath of the plastic surgeon The resulting defect is sometimes surprisingly large—one removes a pennyworth of scar and gets a shillingsworth of bare area This is due to the fact that, where the skin is supple, skin defects heal by the contracture of the scar tissue drawing the edges together, rather than by epithelial growth

* * *

Nature abhors a vacuum, and fills it with a blood-clot, and, as hæmatomata are almost synonymous with wound infection, subcutaneous dead spaces can be obliterated by end-on mattress sutures of non-absorbable material with the loops tied over packs Some sites are more prone to the formation of hæmatomata than others Whereas blood-vessels in the face usually stop bleeding naturally, those in the lower abdomen do not, so every miserable bleeding blood-vessel must be ligated In plastic surgery, pressure dressings are used to press the graft against the recipient area and so prevent hæmatomata The introduction of the crêpe bandage has been the greatest advance in skin-grafting in the 20th century To control hæmorrhages, pressure dressings should be left for four days Six days shall you labour and the seventh is for the evacuation of hæmatomata

Raw surfaces should not be left exposed, because they granulate and form scar tissue Scar tissue is feminine in gender, being perverse at all times it contracts when it should relax, as in strictures, and stretches when it should contract, as in hernia repairs To say that a wound is granulating well is a contradiction in terms If, in transplanting a ureter into the colon, it is allowed to prolapse into the lumen, so that the epithelium where the ureter is cut is not in contact with the epithelium of the colon, the outer surface of the ureter will granulate, forming a circular scar which contracts around the ureter and causes urinary obstruction, sepsis, and death, even if the ureter is put into a defunctioned loop of bowel there will still be stricture leading to urinary sepsis Whitehead's operation for hæmorrhoids fell into disrepute because tension and sepsis led to the separation of the bowel mucous membrane from the skin, and the circular scar led to stricture formation Some surgeons wonder why their colostomies stenose when they do not suture the mucous membrane to the skin, but the wonder is that stricture is not commoner

* * *

The best dressing for any raw surface is a skin graft, and the thicker the graft the less the contracture Repeated dilatations are the signposts of surgical failure, and pull-through methods of anastomosis are bad The failures of prostatectomy, immediate and delayed, are failures to get immediate epithelial cover

Hippocrates said, "Do not operate on growths—it makes them worse", the same rule holds today One should operate on the normal tissues away from the growth, and not cut across carcinomatous tissue For the surgeon, the way to hell is paved with short incisions, for the patient the way to heaven is paved with small excisions, particularly in carcinoma surgery Carcinomata are seldom removed completely, but the growth of those cells that are left behind is held in check by many factors As the radiotherapist depends on the tissue reaction of the healthy patient for the treatment of carcinoma, so does the general surgeon The cynic says that in every case of carcinoma of the breast, recurrences will develop provided the patient lives long enough But the early recurrence appears in the patient who has made a slow postoperative recovery Therefore she should be kept as fit as possible before, during, and after the operation Large operations should be avoided wherever possible, because they lessen the general health of the patient and so upset the hormonal control At the site of successfully treated carcinomata, plastic operations should be avoided lest they liberate carcinoma cells from the scar tissue

* * *

To be a quick operator is good, but speed must never be gained by the sacrifice of any principles Thou shalt not worship speed for its own sake, for it is a false god A quick surgeon never hurries, for speed is not made by overhaste when you drive a car, a high average speed depends not on how fast you go, but on how slowly you don't go Delay is due to indecision, which results from incorrect diagnosis, faulty planning, and lack of experience The repetitive, unproductive movement should be avoided, as in time-and-motion study the hand that puts down the scalpel picks up the artery clip—in one movement Time is saved by attention to many details, such as the position of lights, trolleys, and assistants, and by teamwork Time is saved, therefore, by performing slow, deliberate, economical movements, never unnecessarily repeated Thus, speed becomes the handmaiden of the surgeon and not his mistress

ASSISTANT MEDICAL OFFICER OF HEALTH

CITY OF LIVERPOOL

The spread of influenza from North China and Hong Kong last spring has been reported from many areas (Mulder 1957, Fawdry 1957, Guthrie et al 1957, Lim et al 1957) We describe here its arrival and spread in Liverpool, and compare its course and effects with those of the last sharp outbreak, which attacked Merseyside in January, 1951 (Semple 1951)

Influenza in 1957

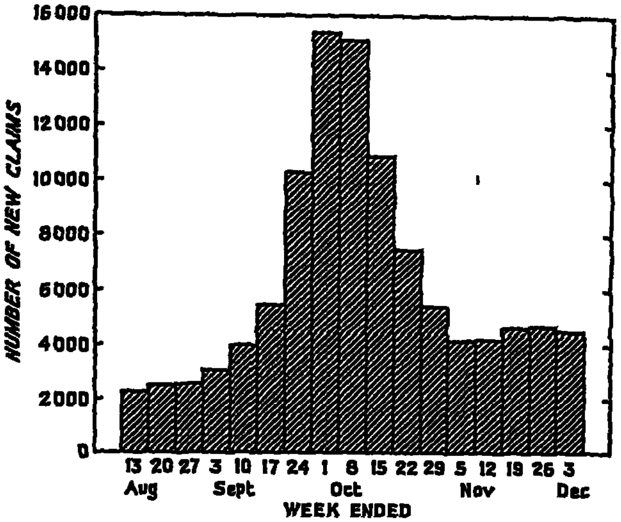
The first influenza patient to reach Liverpool arrived in the s s *Clan Chattan* from Calcutta on June 27 4 more cases were reported in another ship from India on July 1 There was then a break of seven weeks until August 19, when 27 patients arrived in the s s *Hellenes* from South Africa From then until the end of October, 35 ships docked carrying a total of 455 people with influenza The most heavily infected ship was an Indian naval vessel which docked on Aug 27, with 252 cases of influenza aboard

The outbreak in Liverpool started early in September It seemed to be at its height on Sept. 27 and 28

Incidence

The spread of the epidemic was studied day by day by collecting information from as many sources as possible, including the first sickness-claim forms, school absences, and sickness returns from industrial firms in the city and from the Liverpool Passenger Transport Department

The school absence figures rose quickly to a peak on Sept 27 when the average sickness-rate was 39 6% for infant schools, 40 2% for junior schools, and 50% for senior schools The



City of Liverpool Weekly new claims for sickness benefit, 1957

high incidence was found equally in all areas of the city The highest rates were among the older children—a finding unusual in widespread illness of a relatively mild nature Such findings were also noticed in the large independent schools of the city These independent schools started their term about three weeks later than those of the local education authority, and the peak of attack was also about three weeks later, in early October

TABLE I—DEATHS FROM INFLUENZA, PNEUMONIA (INCLUDING BRONCHOPNEUMONIA), AND BRONCHITIS

Nov 2	5	—	14	—	9	14

The new claims for sickness benefit collected by the Ministry of Pensions and National Insurance rapidly increased (see figure) Daily figures of new claims from three local offices of the Ministry were telephoned to the health department The peak of these first sickness claims (see figure), representing the highest incidence in adult insured workers, came in the weeks ending Oct 1 and Oct 8 The peak in adults was therefore a week to ten days later than that in the schoolchildren Figures collected from industry showed similar trends The daily sickness-rates of three large firms (comprising the passenger transport department, a football-pools firm [employing mainly women], and a large mixed factory) were

Date	*Sickness* (%)	*Date*	*Sickness* (%)	*Date*	*Sickness* (%)

and pneumonia continued to increase the high level of 42 in the week ending Oct 26, compared with 5 in 1956 This lag between the peak period for incidence and deaths is usual, but there did seem in this outbreak to be a rather longer period of increased respiratory deaths, though they at no time reached exceptional levels

The weekly mean temperature during the peak of the epidemic was between 52°F and 54°F This represents a level about 1 5°F below the mean temperature for the time of year—a much smaller variation from normal than during the 1951 outbreak

Comparison of 1951 with 1957

The outbreaks of 1951 and 1957 were remarkably similar in size but very different in effect (table II) The sickness first claims were very similar in the four peak weeks of the outbreak in 1951 there were 49,654 claims, compared with 52,560 in 1957 The incidence in children, however, was greater in 1957

The peak of the 1951 outbreak was at the start of a school term, but the absence-rate in the first two weeks of that term (coinciding with the peak of the outbreak) in all schools in Liverpool was 17 7% In the 1957 outbreak, the maximum absence-rate for the two peak weeks was 23 1% This difference is greater than is apparent because the epidemics were at different times of the year In the 1951 epidemic, the absence-rate was 17 7% in early January, when the normal figure would be 12 2%, and in the 1957 epidemic the rate was 23 1% compared with a normal figure for late September of 8 3%

The most striking differences were in the death-rates (table III) The number of deaths from influenza for the six worst weeks in 1951 and 1957 were 469 and 81 respectively The figures for the worst single week are even more striking—202 deaths in 1951 compared with 25 in 1957 These findings are repeated to a less extent with the "other pneumonia" deaths, 329 in 1951 and 143 in 1957

There is evidence that the 1951 epidemic attacked a much larger proportion of older persons in the community in 1951 the old persons' homes in the city were very heavily attacked, whereas in 1957 they almost entirely escaped (only 33 cases of a population of 1351 old persons in the hostels) This would account to some extent for the much lower mortality-rate in 1957, but the season of attack must also have played a part in reducing mortality in 1957

It would be interesting to know whether, in 1957, people over 50 years old escaped illness because they had already been exposed—perhaps in 1918—to a virus of similar strain [1] Perhaps this question can be answered by observing what happens in January and February, 1958, if a second wave appears

Summary

The large influenza A outbreak in Liverpool in September/October, 1957, is described and compared with a similar influenza A outbreak in 1951

Numerically the outbreaks were similar, but in 1951 there was a much higher death-rate and evidence of many older persons being attacked In 1957, the outbreak was much milder and attacked young people, especially schoolchildren

THE PUBLIC HEALTH IN 1956

Chief Medical Officer's Report

A YEAR ago[1] we quoted Sir John Charles' pleasant account of the weather of 1955, and predicted a less happy account for 1956 In his report on the health of England and Wales for that year,[2] Sir Charles tells of the London fog of Jan 4–7 and the thousand extra deaths that followed it, of the "summer" ("no summer since 1880 was colder and wetter and duller"), and of the fog that covered the country from Dec 19 to Dec 23 But, as he points out, man adapts himself to extremes of climate, and the death-rate remained steady at 11 7 per 1000, the infant-mortality rate reached a record low level of 23 7 per 1000 (though the rate of 14 0 in one borough indicates that there is room for improvement), and the number of deaths due to pregnancy and childbirth (including abortion) was 399, the smallest number on record (toxæmia is responsible for many of the deaths, and for much of the perinatal mortality)

THE CANCERS

The heading of the chapter on the malignant diseases is now given a title in the plural, to signify the growing belief that it is more useful to regard them as a group of diseases with a common link rather than as a single disease Some industrial cancers have been almost eliminated, and knowledge or suspicion of the causes of many other cancers gives hope that their incidence may eventually be reduced

The number of cancer-registration bureaus is increasing, this will help to give a truer picture of the morbidity, as distinct from the mortality, of the cancers, but at present trends can be discerned only from the death-rates The comparative mortality index shows the change in the death-rate from a disease, compared with the rate in 1938, corrected for changes in the size and age-structure of the population at risk, it is a better guide to long-term changes of prevalence than the uncorrected numbers of deaths The index for cancer steadily increased in men from 1 0 in 1938 to 1 17 in 1956, in women it steadily decreased to 0 91 Compared with 1955, the total number of deaths from cancer increased by 775 in men and 595 in women In men the number of deaths from most gastro-intestinal cancers declined, and most of the increase was due to cancer of the lung (794 deaths), prostate (225), bladder (61), and lymphatic and hæmopoietic tissue (53) In women the striking increases were in cancer of the lung (120 deaths), breast (85), and uterus (82), and in leukæmia (85 deaths) The incidence of leukæmia has risen more sharply in the past 25 years than that of any other disease except coronary thrombosis and lung cancer, though part of the increase may be apparent, and attributable to better diagnosis The part played by radiation in its cause has been convincingly shown in survivors of atomic-bomb explosions and in patients treated for ankylosing spondylitis, and less definitely in radiologists and in children whose mothers were radiographed during pregnancy But post-irradiation leukæmias have been chiefly acute or myeloid rather than lymphatic, whereas chronic lymphatic leukæmia has contributed much to the increase, and the proportion of cases of leukæmia in which radiation can be definitely incriminated is small

Deaths from lung cancer continue to increase in number (from 1955 to 1956, by 5 4% in males and 4 9% in females) Though in certain occupations (the mining of radioactive ores, the refining of nickel, and the manufacture of asbestos, chromates, and coal-gas) the workers have an increased risk of lung cancer, the two main causal factors against which evidence is substantial are cigarette-smoking and atmospheric pollution Many reports confirm the association between cigarette-smoking and lung cancer—particularly the squamous-celled variety Figures obtained from the mortality among doctors indicate that, even for heavy smokers, the risk of lung cancer developing is lessened if smoking is given up, habitual smokers are deprived of the consolation of "it's too late to stop now" Sir John comments "It's never too late to mend!" The Government have undertaken to see that the public are kept informed about this relationship Urban life, with its exposure to a polluted atmosphere, may be the explanation of the higher incidence of lung cancer in New Zealand among recent immigrants from Britain than in non-Maori natives

---

[1] *Lancet* 1956 ii 1302

[2] Report of the Ministry of Health for the year ended Dec. 31, 1956 Part ii On the State of the Public Health H M Stationery Office Pp 262 9s

CLEAN AIR

Lung cancer is only one of many disorders attributable, in part at least, to atmospheric pollution Sir John welcomes the Clean Air Act of 1956, which sets up a council to advise on clean-air policy, increases the powers of local authorities over the emission of industrial smoke, and empowers the Minister of Housing and Local Government to declare smoke-control areas, thus easing the burden on local authorities These measures may help to dissipate what Evelyn called "the hellish and dismal cloud of seacole" over our cities Meanwhile fog-masks can be prescribed under the National Health Service, and in London certain hospital beds are reserved for patients suffering from the effects of fog Warnings are broadcast when serious fog is predicted

MENTAL ILLNESS

Admissions to hospital for mental illness increased by 5341 to 88,189, but the number in residence fell by 1353 to 149,219 64,011 mental-deficiency patients were under care Outpatient attendances increased from 714,014 to 762,072, many treatments, including shock, psychotherapy, and abreaction are now given in outpatient departments, and more emphasis is now being placed on keeping patients out of hospital For many patients, day hospitals, night hospitals, or short-term inpatient care is best, but others still need long-term admission Even "chronic" patients can often be reclaimed and sometimes return to society Physical treatments (including tranquillising drugs) have helped to make group re-education and occupation possible The result has been that more and more wards have been unlocked—every ward in several large hospitals Patients who formerly vegetated in confinement can now move freely, enjoy recreation, and undertake employment

Mentally deficient children who have to be cared for in institutions may suffer from being deprived of their mothers In some hospitals nursing assistants or older girl patients (under supervision) have acted as substitutes Where possible children are sent home for holidays, conversely, children cared for at home may be admitted for short periods to give the parents a break

Medical officers of health are increasingly acknowledging their responsibilities in preventive psychiatry, through the maternal and child-welfare, school-health, and health-education services

ACCIDENTS

Another responsibility of the local authorities lies in the prevention of accidents, particularly in the home Health visitors and public-health inspectors, in particular, are in a position to detect hazards in the home and suggest remedies. 6908 deaths resulted from domestic accidents, 688 of them in children under 5 years and 5039 in people over 64 Since 1951, the number of deaths has increased in old people and fallen (by 26%) in the under 5's A survey quoted in the report indicates that less than a third of home accidents are caused by environmental factors (bad design, or, more often, lack of maintenance) Some people are accident-prone, thus an American transport company transferred 5% of their drivers with high accident-rates to static work, the number of accidents then fell to a fifth

There has been no decrease in the fatalities from clothing catching fire A British Standards specification for a fireguard (B S 2788), published in 1956, provides for fixation to the wall by hooks and provision for refuelling and removing ash with the guard in place Cellulose materials (especially cotton, flannelette, and winceyette) and flowing garments (especially stiffened underskirts) present the greatest hazard Materials with an anti-flame finish are on sale The report does not deal with transport or industrial accidents

TEETH

In their reports, very many school medical officers have expressed concern at the poor and deteriorating state of children's teeth The increasing scarcity of dentists draws attention to the importance of two ancillary dental workers—the hygienist and the dental nurse The Dentists' Act, 1956, permits the employment of hygienists in private practice (formerly they were confined, in this country, to the Forces and the public-health service), their work is scaling and polishing, and instruction in care of the teeth Dental nurses, now confined to New Zealand, are employed in the public-health service, where their work is the conservation of children's teeth The 1956 Act provides that the "Privy Council may direct the General Dental Council to conduct an experiment in their training and use"

As experiments in North America have shown, fluoridation at optimal levels reduces the liability to decay, and fluoridation experiments are in progress in four areas of England and Wales The experiments involve the periodic examination of 12,000 children, at the first examination over 90% had dental caries

DISABILITIES

During 1956 the total number on the blind register increased by 1336 to 96,019 These are persons "so blind as to be unable to perform any work for which eyesight is essential" 3 6% were totally blind and 11 1% had perception of light only In 80% of cases the cause is unknown The cause of retrolental fibroplasia was made known in 1953, but the incidence in children aged 0–2 in 1954–56 was half that in 1951–53,* altogether 47 cases were registered in 1956

The prevalence of otitis media has been much reduced, and the commonest cause of deafness in adults is otosclerosis This can often be treated successfully by operation or a hearing-aid A much smaller all-transistor aid should be available soon

Congenital deafness, even if not total, may make a child seem backward, and a scheme has been devised whereby children may be tested in the first year of life early training may give the child a better chance of overcoming his handicap

The demand for artificial limbs does not abate 82% of amputations were for disease, chiefly arteriosclerosis and diabetic gangrene, 13% of the patients with disease had cancers Trauma, most commonly industrial and motor-cycle accidents, accounted for 18% of the amputations Training is a particularly important part of the work of artificial-limb centres Patients as old as 90 have been successfully fitted, 50–60% of patients over 60 became fully independent

INFECTIOUS DISEASES

Typhoid fever "*no longer constitutes a public health problem*", though occasional cases arise, some from infected cockles But the number of cases of dysentery, nearly all Sonne, increased by a third to 49,009 Most cases were mild (there were 33 deaths) and conurbations were affected more than rural districts 11,000 cases of food-poisoning were reported to the Registrar General, but 18,500 came to notice through local health authorities and hospitals These represented 7713 incidents (8961 were detected in 1955), and 44 people died (22 with *Salm typhimurium* infections) Processed and made-up meats were the prime vehicles

Measles was in its biennial phase of minor incidence, and the low fatality ratio (0 2 deaths per 100 notifications) suggests that its killing power is weakening

There is a growing demand for laboratory investigation of virus diseases This is more time-consuming and costly than bacteriological investigation 819 strains of poliomyelitis virus were isolated and typed, but "this represents only a fraction of what will be required if our knowledge of viruses is to be rendered adequate for the purposes of clinical identification and for the development of methods of epidemiological control " Except for smallpox and now poliomyelitis, the control of virus diseases has so far proved impossible Of the lately discovered agents, the adenoviruses were identified more often, sometimes in cases where non-paralytic poliomyelitis had been diagnosed. Types 1, 2, and 5 are usually found in tonsils or adenoids, and types 3, 4, and 7 in association with acute febrile respiratory illnesses The evidence suggests that they are not at present of great epidemiological significance, but vaccines prepared from them have been found to reduce the incidence of respiratory infections in troops There was another, much smaller, outbreak of encephalomyelitis at the Royal Free Hospital, and there were small outbreaks and sporadic cases elsewhere with no deaths There were 173 notifications of "acute encephalitis" with 106 deaths 137 deaths were ascribed to poliomyelitis Virological tests indicate that many cases notified as non-paralytic poliomyelitis (1483 out of a total of 3200 in 1956) were really cases of Coxsackie or other virus infections A beginning was made in the large-scale immunisation of children, 140,013 were given two injections

In 1956 there were no deaths from smallpox and 8 (the lowest figure recorded) from diphtheria The proportion of babies vaccinated in various county boroughs ranged from 2 7% to 74 9%, and of babies immunised against diphtheria from about 30% to 70% The size of the immunisation index seems to depend more on the enthusiasm and vigilance of the local health authority than on family and social attitudes (The occurrence of 2 cases of smallpox in 1957 indicates that the danger still exists) B C G vaccination is being given to increasing numbers of people, especially schoolchildren, a promising new freeze-dried vaccine has been under trial In this country, however, the spectacular decline in deaths from tuberculosis, and now notifications (deaths decreased by 17% and notification by 7% from the previous year), is to be attributed less to vaccination than to epidemiological methods (such as the detection, isolation, and treatment of infected persons and examination of contacts) and effective treatment, especially chemotherapy An encouraging feature of the decline in notifications is that it is most evident in the younger age-groups, which augurs well for the future The highest death-rates from tuberculosis are now in the age-groups 65–69 for men and 75–79 for women

Chemotherapy is also largely responsible for the fall in the fatality ratio of meningococcal infections (now steady at about 18%, perhaps because many cases are missed in the early stages), and for much of the fall in the number of new cases of venereal disease since the peak year, 1946 (by about 80% for syphilis and 60% for gonorrhœa) But after reaching low levels in 1955 and 1954 respectively, both these diseases are now becoming commoner, as are non-gonoccocal urethritis in men and trichomonas vaginitis in women Most infections are not in immigrants or prostitutes Gonorrhœa " is clearly not under control, and one reason for this has been the tendency to play down its importance by over emphasising the power of penicillin it now seems likely that in some areas strains of gonococci partially resistant to penicillin may be coming into circulation "

Sir John refers also to the "perplexing problem" of staphylococci resistant to antibiotics, which are dangerous in their own right and, by producing penicillinase, enable hæmolytic streptococci " to resume their former place as public enemies No 1 of the operating theatre " He attributes the increasing proportion of resistant strains to the indiscriminate use of penicillin in unsuitable conditions

THERAPY

Sir John makes few comments on treatment, but indicates some further examples of its misuse Thus, though some tranquillising drugs are undoubtedly useful in the treatment of severe psychoses, they may give rise to severe and even fatal toxic reactions, and are often disappointing in the treatment of the simple common emotional disorders for which they are very often prescribed

702,593 bottles of blood were issued by the regional transfusion centres in 1956—6% more than in 1955 and 90% more than in 1949 " It seems possible that part at least of the increase is caused by a less discriminating use of transfusion, and it is difficult not to conclude that some transfusions are given unnecessarily " This would be serious enough if the only disadvantage of excessive transfusion were the dangers of the method and the cost of the necessary organisation, but it seems that we are near the point where a further increase in demand will not be met by an equivalent increase in the donor panel 12% of the blood collected was contributed by British and American Forces stationed in this country

Medicine and the Law

Is Automatism a Defence to Crime ?

In recent years much of the discussion on criminal responsibility has centred on the death penalty for murder This particular controversy will no doubt abate now that there is the defence of diminished responsibility and the death penalty has been abolished for certain murders, but there remains both scope and need for further medicolegal discussion of the element of intention in criminal liability The case of Hill *v* Baxter [1] raised—but left unsettled—the question whether automatism is a valid defence to a criminal charge

The defendant had been charged with dangerous driving The magistrates concluded that, after a certain point, he was not conscious of what he was doing, and inferred that he was then incapable of forming any intention as to his manner of driving They therefore dismissed the charge On the prosecution appealing, the Lord Chief Justice said that the magistrates evidently meant that the driver was in a state of automatism His Lordship observed that there was no case in either English or Scottish law in which the defence of automatism had been set up or been the subject of judicial decision In the present case, his Lordship was content to rest his judgment on the ground that there was no evidence which justified the magistrates' finding that the defendant was not fully responsible in law for his actions, and that his intention was immaterial because the prohibition against dangerous driving was absolute Mr Justice Devlin also thought there was no need in the present case to determine just what part automatism played in liability for crime, it was a novel point and the answer would depend, among other things, on the nature of the liability which the prosecution had to establish

---

[1] *Lancet*, Jan. 4 1958, p 47, *Times*, Dec 20, 1957

In establishing criminal liability, the question of intention may enter in what the lawyer regards as two different contexts One basic rule applies to all criminal offences—namely, that the accused must have committed an act prohibited by the law or he must have omitted to do something required by the law Furthermore, this act or omission must have been voluntary An involuntary act or omission is one which is not willed, and Halsbury's *Laws of England* give the following examples

> " an act done by a person in a state of unconsciousness, as in sleep, or by a person of such tender years or in such a state of idiocy or insanity that he has, or is deemed to have no mind and therefore no will, or by a person who is constrained by overwhelming force An act or omission is voluntary in this sense if it might have been avoided by the exercise of reasonable care "[2]

In the case of many criminal offences, it is also necessary that the accused should have been guilty of a legally blameworthy condition of mind known as *mens rea* This element is essential in all the common-law crimes with one exception, but is not regarded as essential in some statutory offences Thus, as the Lord Chief Justice pointed out, in the offence of dangerous driving the intention of the driver is immaterial, even an honest error of judgment may render a motorist guilty of dangerous or careless driving Where *mens rea* is an essential element, proof of guilty intention rests in the first place upon the prosecution, in many cases, however, the facts themselves will raise a presumption that the accused had a guilty intention, in which case it will be upon him to rebut the presumption

It would seem—particularly from Mr Justice Devlin's judgment—that a plea of automatism might be relevant in establishing that an act or omission was involuntary in the sense considered above, or in disproof of *mens rea* where this is an element in the offence In either case, it would seem obligatory upon the defence to produce some evidence of automatism, though the degree of proof might vary according to the nature of the defence If the defence is that the act or omission was not "voluntary ", the court might require a higher standard of proof than in a case where the defence is a denial of *mens rea*

Medical Reports in Criminal Proceedings

In civil proceedings the use of agreed medical reports is a recognised practice which saves both time and expense One would suppose that a similar procedure could be adopted in criminal cases, but apparently this is regarded as improper In Hill *v* Baxter[3] a bench of magistrates considered the charge of dangerous driving The defence produced two letters from a doctor dealing with the defendant's condition, the prosecution had no objection to these letters and they were accepted by the magistrates This procedure was condemned by the Lord Chief Justice Agreed medical reports, he said, have no place in criminal courts, where evidence must be given on oath and be subject to cross-examination unless there is a statutory exception allowing documents or certificates to be put in

Special Articles

NEW YEAR HONOURS

The list of honours published on Jan 1 contains the names of the following members of the medical profession

Baronet

Sir Harry Platt, M S Lond, M D Manc, F R C S
Lately president, Royal College of Surgeons of England, emeritus professor of surgery, University of Manchester

G C V O

Sir Stewart Duke-Elder, K C V O, M D, D SC St And, F R C S

K B E (Military)

Air Marshal **Patrick Brunton Lee Potter**, C B E, M D Sheff, Q H S
Director-general, Royal Air Force Medical Services

Surgeon Vice-Admiral **Robert Cyril May**, C B, O B E, M C, F R C S, Q H S
Medical director-general of the Navy

Knights Bachelor

Kenneth Cowan, M D Belf, M R C P E, Q H P
Chief medical officer, Department of Health for Scotland

Herbert Ronald Robinson Grieve, M B Sydney
Member of the New South Wales medical board

Hans Adolf Krebs, M A Cantab, M D Hamburg, F R S
Whitley professor of biochemistry, University of Oxford, director of the Cell Metabolism Research Unit, Medical Research Council

William Bentley Purchase, C B E, M C, M B Cantab
Coroner, H M Household and northern district of London

William George Dismore Upjohn, O B E, M D, M S Melb, F R C S, F R A C S
Consulting surgeon, Royal Melbourne Hospital

Ralph Whishaw, C B E, M B Sydney, F R C P, F R A C P
Physician, Royal Hobart Hospital, Tasmania

C B. (Military)

Major-General **Douglas Bluett**, O B E, M B Dubl, Q H P

Air Vice-Marshal **Frederick Elvy Lipscomb**, C B E, M R C S, Q H P

Surgeon Rear-Admiral **Eric Thomas Sutherland Rudd**, C B E, M B Dubl, F R C S E

C.M G.

Donald Dixon McKenzie, M B N Z, F R C S, F R A C S
Senior surgeon, Auckland Public Hospital

C B E (Military)

Group-Captain **Hugh Cuthbert Sutcliffe Pimblett**, M D Durh, R A F

C B E (Civil)

Alexander Brown, M B Edin, F R C P E
Professor of medicine, University College, Ibadan

Trewavas Pearce Eddy, M R C S
Director of medical services, Sierra Leone

Gordon Lilico, M B Edin
Lately a principal medical officer, Ministry of Health

John Campbell McIntyre Matheson, D S O, M B Glasg
Principal medical officer, H M Prison, Brixton

Lambert Charles Rogers, V R D, F R C S, F R A C S, F A C S
Professor of surgery, University of Wales

---

[2] 3rd ed vol 10

[3] *Times*, Dec 20, 1957

Seymour Cochrane Shanks, M D Glasg , F R C P
Director, X-ray diagnostic department, University College Hospital, London

Clarence Edmund Smith, L M S Singapore
Assistant director of medical services (tuberculosis), Singapore

Lieut.-Colonel George Henderson Stevenson, O B E., M C , M B Edin , F R C S E
Lately chairman, executive committee, British Red Cross Society (Scottish branch)

Edwin Alfred Trim, O B E , M D Cantab
Director of medical services, Uganda

O B E (Military)

Surgeon Lieut.-Commander David Geoffrey Dalgliesh, M R C S , R N

Squadron-Leader John Ernsting, M B Lond , R A F

Lieut.-Colonel Charles McNeil, M B Cantab , R A M C

O B E (Civil)

Frank Richard Ashton, M B Edin
Medical superintendent, Nethersole Hospital, Hong Kong

Charles Bowesman, M D Dubl , F R C S E
Formerly specialist (surgery), Ghana Ministry of Health

Harold Crawford, M B Melb , F R A C S
Orthopædic surgeon, Children's Hospital, Brisbane

Katherine Mary Hirst, M B Lond
A senior medical officer, Ministry of Health

Thomas Victor Humphreys, M B Belf
Lately first secretary and medical officer, H M Embassy, Moscow

Reuben Jacobson, M B W'srand
Director of medical services, Basutoland

Leonard Ross Mallen, M B Adelaide, J P
Medical practitioner, Lower North District, South Australia

Pan Tsoh Chen, M B
For social welfare services, North Borneo

Ivan Samuel Parboosingh
Senior medical officer, Jamaica

John Patrick Sexton, M B Edin
Regional senior health officer, Northern Region, Nigeria

Clarence Edmund Smith, L M S
Assistant director of medical services (tuberculosis), Singapore

Joseph Stanley Thomas, M R C S , J.P
General practitioner, East Ham

Thomas James Russell Warren, M B Dubl , F R C.S E
Director, Samaritano Hospital, São Paulo

Philip Randal Woodhouse, D S O , M C , V D , M B N Z
President, New Zealand Catchment Boards' Association

M B E (Civil)

George Francis Nicholas Anderson, M B Dubl
Senior medical officer, Iraq Petroleum Company in Qatar

Elizabeth Abimbola Awoliyi, M R C P I
Medical officer, Federation of Nigeria

Abraham Johannes Petrus Coetzee, M R C.S
Chief medical officer, Rhokana Corporation, Northern Rhodesia

George Millar Edington, M D Glasg
Formerly specialist pathologist, Ghana Ministry of Health

Irene Elizabeth Beatrice Ighodaro, M B
For social welfare services, Western Region, Nigeria

Frank Stanislaus le Merle
Lately medical practitioner, Basra

Latima Kamya Musoke
Medical officer, Uganda

Olive Hope Robertson, M B Edin
President, Federation of Women's Institutes, Southern Rhodesia

James Scott Robinson, M R.C S
District medical officer, Dominica, Windward Islands

Cyril Augustus Wallace, M B Belf
Medical officer, Tanganyika

In England Now

The reminiscences of the elderly can be tedious, but those of Uncle Edward, now rising 93, have a stark simplicity which amply repay the annual visit Last year's was about the benevolent rat he had once observed piloting its blind mate along a gutter by means of a straw held between its teeth This year Uncle set the ball rolling by remarking innocently that he had just received a Christmas card from Eric Little "He has sent me one regularly for over fifty years" So we dutifully asked who Eric Little was But Uncle was not to be hurried It appeared that in 1887 when he was senior obstetric officer at his alma mater a colleague in practice nearby had sent him an S O S because he was having difficulty in delivering the baby of an elderly primigravida "And no wonder," said Uncle, "because it was not an ounce under twelve pounds" However it appeared that Uncle was quite used to landing twelve-pounders, and he was soon able to hand the baby over to the gamp and turn his whole attention to the mother who was having repeated convulsions which were rather worrying Here again Uncle's skill prevailed, though it was some two hours before his unspecified therapeutic efforts were rewarded, and he could turn once more to the baby "But the baby is dead, Doctor, it was born dead" "Nonsense," said Uncle, "where is he?" It transpired that the baby had been tidily wrapped in brown paper and deposited on top of the dustbin Uncle lost no time in retrieving his charge and divesting it of its make-shift shroud "It certainly looked white and was not breathing, but through my stethoscope I could hear the heart, ten beats to the minute and very muffled" So Uncle, undismayed, proceeded vigorously to apply a method, again unspecified, of resuscitation, which, he avers, is known in the hospital to this day as MacGillicuddy's method of reviving the apparently dead For the third time his virtuosity was crowned with success The baby turned blue, then breathed, and finally bellowed "And soon I was able to place Eric Little in his mother's arms, and hence the Christmas card No, no, his mother never told him the truth—she simply said it was a miracle." Uncle ended modestly

* * *

Well 1958 has certainly come in with a bang There's the geophysical jamboree at the Pole, there's Sputnik I hourly getting nearer, and above all Mr Fairbrother has pain in his chest on exertion Antarctic news has not unnaturally left most people cold, Sputnik I is best forgotten, but Mr Fairbrother's catastrophe has hit the great British Public where it hurts most It stands to reason that if a hero of the Light Programme gets pain on climbing hills and is to have a E C G then something is bound to happen After all what is good enough for him is good enough for the Common Man and the next thing we will find will be our dyspeptics scorning our mag trisilicate and demanding specialists and E C G s galore The Light was friendly when I phoned to plead for a change in the story before Mr Fairbrother was actually in extremis It saw my point It thanked me for phoning, but it promised nothing

That night one of my coronaries sprang an embolism Next evening two had relapses It may mean nothing, but perhaps it does

* * *

In Calgary the Christmas and New Year campaign against people who drive cars when they are not fit to do so is again being widely advertised,[1] and once again the police will DRIVE-YOU-HOME if you are "impaired" and ask for help No names will be named, and no charges will be laid This campaign has helped greatly to lessen the recurring toll among merrymakers, and this year the men who man the *petrol* pumps are going to help by offering coffee and doughnuts *free* along with the gas and oil at service-stations in Regina and Saskatoon, and probably in Calgary as well They hope that the fluid balance will be so well maintained that nobody will be tempted

TICK-BORNE MENINGOENCEPHALOMYELITIS IN SWEDEN

SIR,—During recent years cases or epidemics of meningoencephalomyelitis caused by agents related to the Russian spring–summer/louping–ill group of tick-borne viruses have been reported not only from Russia but also from Czechoslovakia,[1] Hungary,[1] Slovenia,[2] Austria,[2] Poland,[3] Sweden,[4] and Finland [5]

The first verified Swedish cases were in the summer of 1954 When, in 1956, again a large proportion of the cases of aseptic meningoencephalitis in Stockholm were found to have been tick-bitten, an enlarged study was undertaken This time tissue-culture methods were adopted for the assay of neutralising antibodies and for the production of complement-fixing antigen The results so far obtained seem to be of some general interest

At first we tried the virus-cell system introduced by Oker-Blom [6]—i e , a strain of louping-ill virus adapted by him to give cytopathic changes in cultures of HeLa cells In our laboratory, however, this virus strain caused only late and partial changes, which varied too much to be used for quantitative tests The cytopathic effect was not much better on KB cells Detroit-6 cells[7] were, however, found to be considerably more sensitive, the changes appeared earlier, were more extensive, and were reproducible The response of the cultures was the same following 12 passages of the virus Actually, a suspension of a mouse brain infected with a strain of louping-ill virus (kindly supplied by Dr F O MacCallum) that had never been carried in *tissue-culture gave as clear-cut cytopathic changes Moreover,* the titre was the same (*$10^{-7\ 5}$* per ml of the 10% suspension) in Detroit-6 cultures, and following intracerebral inoculation into three-week-old Swiss mice

The stationary-tube cultures of Detroit-6 cells used for all neutralisation tests were grown out on a medium of Parker 199 with 40% human serum and maintained on bovine amniotic fluid fortified with 10% horse serum and 0 5% bactotryptose Serial dilutions of serum were tested against a constant dose (1000 TCD_{50}) of virus, the mixtures being incubated at 37°C for one hour before inoculation This dose of virus caused obvious microscopic changes within three days, the final reading of the neutralisation tests was made six or seven days after inoculation A complement-fixing antigen that could be used without further treatment was prepared in Roux flask cultures *Guineapig serum* was, however, substituted for the horse serum in this instance as the antigen otherwise became anticomplementary

Neutralisation and complement-fixation tests were performed on the sera from 159 patients with the clinical diagnoses of aseptic meningitis, meningoencephalitis, or poliomyelitis, who were treated at the Hospital for Infectious Diseases in Stockholm during the latter half of 1956 Neutralising antibodies were found in the convalescent sera of 66 patients, and complement-fixing antibodies in 65 of these *Moreover,* significant rises in titre (at least 4-fold) were found in the convalescent sera of 26 patients, most often with the complement-fixation test On the other hand, none of 44 healthy blood-donors in Stockholm had neutralising antibodies against louping-ill virus About 70% of the patients with antibodies reported that they had, within a couple of weeks before their disease, been bitten by ticks when on vacation somewhere in the Stockholm region during June-September The corresponding figure for patients without antibodies was only 6% The tick *Ixodes ricinus,* a known vector of this virus, is common in Sweden The probability that a tick-borne virus, related to the Russian spring-summer/louping-ill group, caused the disease in the majority of patients with such antibodies is strengthened by the fact that no indications of other virus infections were found in this group Thus no agents cytopathic for human embryonic lung cultures were recovered from stool specimens, and, furthermore, the complement-fixation reaction with heated poliovirus antigens (which responds quite broadly also to infections with several other enteric viruses, such as ECHO 6[8] and ECHO 9), was consistently negative or gave only minimal titres On the contrary, the 93 patients lacking antibodies against louping-ill virus included 25 excretors of enteric viruses (11 polioviruses and 14 other cytopathic agents) and 7 cases of mumps, high and often rising complement-fixation titres against heated poliovirus antigens were also common in this group

The following clinical data have been computed from all 66 patients having antibodies against louping-ill virus The clinical picture corresponded well with that described in Central European tick-borne encephalitis

Thus 75% had a diphasic course The incubation-*period*—i e , the interval between a single known tick bite (28 cases) and the first onset of disease—varied between two and fourteen days (mean six days) The prodromal stage lasted for two to twelve days (mean six days) It was characterised by moderate fever, headache, and muscle pains After a free interval of two to twenty-five days (mean eight days) *the major disease followed Dominant symptoms* were now high fever (lasting for five to twenty-two days, mean eleven days), splitting headache, neck rigidity, and vomiting About half the patients had at least some clinical sign of encephalitis, such as disturbance of sleep, mental confusion, somnolence, vertigo and/or ataxia Not less than 44 of the 66 patients had, however, a definitely pathological electro-encephalogram during the first week and lasting for one to four weeks 17 patients had transient paralysis (5 shoulder and/or upper arm, 1 shoulder and leg, 2 leg, 3 eye, 2 facial, 1 pharyngeal, 3 intestine or *bladder) Lumbar puncture on admission revealed a moderate* pleocytosis with *mostly lymphocytes* and a relatively high protein content

1 of the 66 patients died three weeks after onset of the meningoencephalitis The convalescence of the others lasted between two and fourteen months (in 75% four months or less) The main complaints were the common ones after an encephalitis—i e , headache following mental or physical stress, disturbance of sleep, and inability to concentrate and to memorise

THE NEW CHINA

SIR,—May I correct two statements in Dr Fox's account of the New China (Nov 9)?

On p 938 he says that " in the various medical colleges of the 1930s and earlier, teaching was usually in English but sometimes in other foreign languages, and the profession was disunited thereby " This implies that all medical colleges taught in a foreign language, which was usually English Actually, although some of the better-known colleges, such as the Peking Union Medical College, did all teaching in English, a considerable number taught in Chinese The West China Union University, with which I was associated, and Cheeloo University, both did almost all their teaching in Chinese These were two of the more important Christian medical colleges in China It is true that some English was used—e g , for hospital histories—but lectures were almost entirely in Chinese The fact that China today has a medical terminology is due very largely to the efforts of missionaries, and Causland's *Medical Lexicon* is still being reprinted in China

Also on p 938 is the statement " I am told that after graduating in arts, qualification as a doctor took eight years and qualification as a nurse took five (which meant that too few nurses stayed the course) " Both statements are quite untrue, as a reference to the calendar of the Peking Union Medical College will show The entire course (premedical, medical, and one year of internship) took eight years Three years premedical, taken in any suitable university but usually in Yenching University, then four years of medicine (as in the U S A), followed by one year of rotating internship was the total requirement for medical qualification in the P U M C At the

end of the first year of medical studies, Yenching University usually conferred a B SC degree—that is after three years in Yenching and one year in the P U M C The total requirement of West China and of Cheeloo was seven years, and of almost all other medical colleges in China it was six As for the nurses, the P U M C certainly did not require an arts degree before entry The total length of their nursing course—a degree course—was five years In nearly all other schools of nursing the course was three years in length, and no degree was given The P U M C nursing course was specially designed to train a relatively small number of future principals of schools of nursing, nursing superintendents (matrons) of hospitals, &c

LESLIE G KILBORN

THE REINFORCEMENT OF TENDON-REFLEXES

SIR,—Dr Penman (Jan 4) raises the interesting question of the effective stimulus for reinforcement We do not think that the "alerting" if unaccompanied by the effort of muscular activity is sufficient For example, in fig 3a of our paper the subject had been warned to be ready to grasp as soon as he felt the hammer blow That he was fully alert is shown by his short reaction time, yet there was no reinforcement On the other hand, we have noticed that some subjects tense their muscles as soon as they are alerted and we suspect that the effort involved in this movement accounts for the anticipatory reinforcement described by Dr Penman We agree that movement is not necessary, for we have observed reinforcement of the ankle-jerk produced by an effort to grasp when the forearm muscles were so paralysed by decamethonium that no detectable movement resulted We feel that the effort to move, whether accompanied by a movement or not, is the effective stimulus for reinforcement, and this is what we intended to imply in our paper

A J BULLER
A C DORNHORST

TRICHOMONAS VAGINITIS

SIR,—Dr Marjorie Murrell (Dec 21) criticises our article on the action of 'Locan' pessaries in trichomonal vaginitis The following are her main points and our replies to them

1 That *our dosage of 'Penotrane'* was not that now recommended by the manufacturers The dosage used was the routine for the particular clinic and gave satisfactory results when the organism was sensitive The failure-rate was due to genuine resistance in the strains and agrees exactly with that found in other, earlier, trials and in general experience

2 That the exclusion of known promiscuous patients from the experimental series invalidates the comparison with the controls It was not possible retrospectively to discover whether the controls were promiscuous or not In any case the number of persons excluded from the trial was only five

3 That there is in her experience a higher rate of sensitisation than we report Her cases were treated elsewhere and when she saw them there was vulval eczema in 3 out of 12 The absence of eczema before treatment has not been established

In our cases, and apparently in Dr H C Perry's series (Dec 21), there was no evidence of sensitisation The case we mention complained of irritation but there was no inflammation or excoriation Sensitisation will occur in some patients but the frequency should be low The manufacturers of locan tell us that the same chemicals in other topical preparations are giving this in only 2 out of 15,000 cases treated

The remaining criticism of our paper is directed to the nature of the trial It appears to be widely believed that a mathematical estimate cannot be obtained unless alternate or randomly selected cases are treated and the remainder given blanks This is not true if, as in trichomonas infestation, there is little chance of spontaneous cure during the period of observation and if the cure-rate for the population at large under alternative treatment has been established over many years

The purpose of using a group of controls was to establish that the clinic population was not self-selected and notably atypical Since the figures for both preparations used agreed with earlier trials and with the accepted figures for failures in treatment, such a comparison was fair Using the familiar χ^2 technique, either with the series as published or with the addition of those cases still under treatment or in which the follow-up had been less than three months (giving 18 more cases with 3 relapses in previously relapsing patients, these now being taken as failures), the probability that the favourable results are due to a sampling error *is less than 0 001*

St Mary's Hospital Medical School,
London, W 2

H C STEWART

EFFECT OF *d*-TUBOCURARINE CHLORIDE ON BLOOD-PRESSURE OF ANÆSTHETISED PATIENTS

SIR,—As Dr Langton Hewer says in his interesting letter of Oct 26, there have been a number of reports of a rise of blood-pressure following the injection of *d*-tubocurarine chloride As far as I am aware, however, it has not been conclusively shown that such a rise can be attributed to the effects of this drug

The rises in my cases were mostly small—only three being greater than 10 mm Hg—and were not statistically significant The blood-pressure of the anæsthetised patient is not constant but varies in either direction for a variety of reasons, some of which are *ill* understood It was to this variability that I attributed the small rises in blood-pressure which I observed There is nothing in my results, therefore, to support the contention that *d*-tubocurarine chloride may raise the blood-pressure of some patients

I do not think that Dr Burchell's interesting remarks (Nov 9) are applicable to my results because control of respiration had been established in most of my patients at least 5 minutes, usually more, before the injection of *d*-tubocurarine chloride

EDWARD T THOMAS

VALIDITY OF THE UREA METHOD FOR ESTIMATING TOTAL BODY-WATER IN MALNUTRITION

SIR,—Dr Srikantia and Dr Gopalan (Nov 23) recommend the use of urea for measuring total body-water There are a number of points to be remembered

A given dose of urea may not be completely absorbed, this may make calculations of total body-water inaccurate After administration of doses of the order of 100 g urea a day for the treatment of peptic ulcer, the blood-urea did not always increase as expected There were increased levels of urinary urea, but not to a sufficient degree, one could only assume an incomplete absorption of these relatively large doses My unpublished studies seem to confirm this view, but since unabsorbed urea may appear as fæcal ammonia rather than as urea, exact deduction is difficult

If urea is fully absorbed it must not be assumed that it will diffuse into all the body-water We have shown [1] that urea permeates slowly into the central nervous system

---

[1] Conway, E J; FitzGerald, O *J Physiol* 1942, 101, 86

Furthermore, some parts of the central nervous system may be impermeable to urea

Finally, it should be remembered that urea is not biologically inert Indeed, this is explicit in Dr Widdowson's suggestion, and the purpose of the paper by Dr Srikantia and Dr Gopalan was to assess its importance Urea may be broken down by gastric urease and by bacterial urease We have found that the amount of gastric ammonia after urea administration (orally or intravenously) might be quite great[2] This would affect the value of the urea as a test substance for total body-water These considerations (apart from the reference to the central nervous system) possibly apply only under somewhat unusual circumstances, such as where large amounts of urea are being used or where incipient renal failure is present They are, however, worth remembering

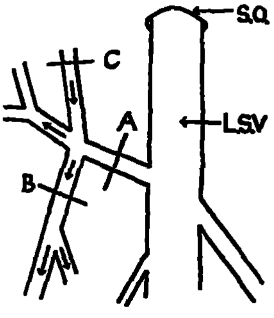
and University College, Dublin

OLIVER FITZGERALD

THE STRIPPING OF VARICOSE VEINS

SIR,—Some of us have been performing this operation long enough now to come across an occasional recurrence When this is at the site of high resection or " top-tie", and the notes show that every single branch joining at that point has been resected, we have to ask ourselves why the bypass has occurred

I think the enclosed diagram may help to give us the answer in other words, resecting the joining branch *close* to the main trunk of the long (internal) saphenous vein may still allow a bypass through the distal branches To make quite sure that this state of affairs should not arise, it is necessary to resect and ligate at the points diagrammatically represented at C and B in the accompanying figure



Ligation of branches of long saphenous vein A site of usual ligation B, C: additional ligatures needed to prevent bypass L.S V: long saphenous vein S O saphenous opening

The most common cause of " recurrence " that comes my way I find to be failure to strip the short (external) saphenous vein when dealing with the eradication of the internal saphenous vein In a high percentage of cases this extra procedure I find to be necessary at the original operation

There are many other causes of recurrence, but I do feel that these two are of sufficient importance for our special attention

London, W 1

R ROWDEN FOOTE

A THYROID ASSOCIATION

SIR,—The Fourth International Goiter Conference is to be held in Britain in 1960 and the American Goiter Association, which usually holds its annual meeting in one of the cities of the U S A, is on this occasion holding its annual meeting in London in conjunction with the International Conference The London arrangements for these meetings are being made by a committee of the London " Thyroid Club "

These developments have raised the question of whether there should be formed a " Thyroid Association of Great Britain " or " of Europe ", which should probably be linked in some way to the Society for Endocrinology and the section of endocrinology in the Royal Society of Medicine If those who feel that some such association should be formed would notify the undersigned, the amount of support for this idea could be ascertained If it then seems desirable a preliminary meeting will be arranged, possibly in association with the national joint meeting of the Society for Endocrinology and the section of endocrinology in the Royal Society of Medicine

INTELLIGENCE OF DRIVERS

SIR,—Although I have not experienced the hazard described by Dr Millman (Jan 4) I have often thought that the sign " dual carriageway " itself offers a potential danger Neither " dual " nor " carriageway " is a word commonly used in speech and it is doubtful if the meaning of " dual " would be readily comprehended by the semi-literate The expression " dual carriageway " is liable also to be misinterpreted, for ordinary roads can be regarded as dual carriageways in the sense of providing two ways or directions of movement for vehicles Perhaps this is why the expression is not to be found in the Highway Code

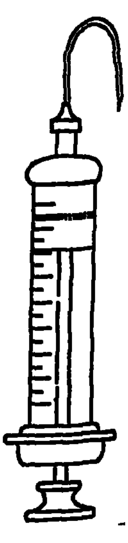
Middlesex

A G J EVANS

AID FOR VOLUMETRIC FILLING OF SYRINGES

SIR,—Preparation of an accurately measured volume of fluid in a syringe is often associated with spilling and dribbling of the excess fluid as an attempt is made to get rid of air-bubbles This is especially troublesome when one is handling frothy fluid, such as blood, or radioactive material, where it is essential to avoid contamination



The problem can be solved by the simple means of using a U-shaped needle, shown in the accompanying figure This is prepared by bending an 18-gauge standard hypodermic needle, $2\frac{1}{2}$ in long, into the suitable shape, with careful manipulation the standard steel needle will take this strain without snapping, especially if first heated

The solution is drawn into the syringe beyond the graduation mark in the usual way, the U-needle is then fitted to the nozzle of the syringe which is held inverted When the piston of the syringe is pushed, all air bubbles are ejected, and excess fluid is returned to the stock bottle held in position below the needle-point During this manipulation sterile conditions can be maintained with ease

ENZYME TESTS FOR GLUCOSE

SIR,—From time to time adverse reports have been published on the enzymatic testing of urine for glucose Recently Tunbridge[1] suggested an error of 11% when urine is tested in this manner On the other hand, the advantages of this method are such that it should not be rejected lightly unless there is clear evidence that it is unreliable

In my diabetic clinic at the Beverley Westwood Hospital, each patient brings with him four specimens of urine which have been passed at specified times on the previous day My present series covers 932 samples of urine each of which was tested by the ' Clinistix ' method and also by the standard

---

[2] FitzGerald, O, Murphy, P *Irish J med Sci* 1950, March, p 97

[1] *Prescribers Notes,* 1957

Benedict technique in a water-bath The urine is tested by a laboratory technician Of those 932 samples 12 gave a false positive reaction On the other hand, not one gave a false negative. False positives are of little importance, as under normal routine all urines which give a positive reaction to 'Clinistix' must have this confirmed by water-bath test I strongly suspect that, in the case of at least some of the false positives, they were read off later than thirty seconds Those results would suggest that it is a reliable test for glucose in urine.

INFANTILE GASTROENTERITIS

SIR,—I should like to support Professor Watkins' condemnation (Dec 21) of the indiscriminate use of antibiotics in infantile digestive disorders I use the latter term deliberately because I agree with Dr Easton (Dec 28) that most cases of so-called gastroenteritis seen nowadays are non-infective, rather do they result from dietetic mismanagement by the mother because of ignorance or indifferent professional advice

Present-day reliance on bottle-feeding leads to trouble at both the major weaning periods (1) when the mother first attempts to wean the infant from the breast on to the bottle, usually after leaving hospital, (2) when mixed feeding commences and choice of other natural foods becomes a problem At both times the divided responsibility of her advisers (hospital, child-welfare clinic, health visitor, midwife, and family doctor) does not favour unanimity of professional opinion, though it is true that the necessary explanation and reassurance is time-consuming The reason why babies do better in hospital is surely not the use of antibiotics, or a lessening of doubtful infectivity, but the skilled nursing (rather than medical) attention which is given to feeding, its timing, and above all the absence of panic and fussing

MANIPULATION FOR BACKACHE

SIR,—We must all applaud Mr Bremner (Jan 4) for drawing renewed attention to the useful part played by manipulation in the relief of backache This fact calls for reiteration until its value is recognised at every hospital in the country When this becomes so, patients requiring such treatment will no longer have their time wasted by futile physiotherapy nor be forced to go outside the N.H S to seek relief from lay manipulators

While I can only admire Mr Bremner's courage in manipulating under anæsthesia, this unfortunately militates against a good result. Comparison between his 10% complete relief after one session with the 57% reported by Barbor[1] and the 49% when anæsthesia is avoided,[2] shows clearly what a handicap anæsthesia is The reason is this

We are agreed that the aim is to restore a painless range of movement to the affected lumbar joint(s) But it often happens that forcing movement in one way does good whereas in another does harm Which technique is most suited to any one case can be discovered only by questioning the patient about his pain and assessing his range of straight-leg raising and of lumbar movements after each manœuvre Anæsthesia deprives the manipulator of this necessary guidance Moreover, the manipulation should cease when a painless range has been restored How can the manipulator know that this point has been reached unless the patient can stand up, move in each direction, and report the result? Good work carried out under adequate control demands a fresh assessment of the case after each separate manœuvre such as is rendered impossible by anæsthesia[3]

There is another disadvantage the small number of patients that can be treated if admission for the night, use of the theatre, and the services of an anæsthetist are needed Moreover, both hospital and patient are reluctant to repeat so elaborate a routine at whatever intervals prove necessary This is important, for relapse within three years amounts to over 40%, and some patients need treatment once or twice a year

We are careful to avoid physiotherapy after a successful manipulation, and regard it as useless when manipulation fails, hence our only after-treatment is postural instruction and perhaps a corset

Our statistical assistant, Mrs Granger-Taylor, has supplied us with the following figures for 370 patients, all seen in 1953 and followed-up for not less than three years

Pain in Back (46%)

(1) Treated by manipulation, 58%
  Well in one session, 49% } 60%
  Well in two sessions, 11% }
  Recurred within three years, 44% of those relieved by manipulation
(2) Treated by traction, 13%
  Well in two weeks, 38%
  Recurred within three years, 20%
(3) Treated by epidural injection, 17%
  Well, 43%
  Recurred within three years, 21%

Sciatica (54%)

(1) Treated by manipulation, 31%
  Well in one session, 33 5% } 45%
  Well in two sessions, 11·5% }
  Recurred within three years, 40%
(2) Treated by traction, 25%
  Well in two weeks, 68%
  Recurred within three years, 20%
(3) Treated by epidural injection, 26%
  Well, 66%
  Recurred within three years, 18%

These are personal figures At St Thomas's Hospital, as is well known, nearly all manipulation is carried out by physiotherapists It is thus probable that statistics based on their work would show results in rather more sessions, since many are still students However, these students have manipulated with success in cases where manipulation under anæsthesia had failed, hence I feel sure that Mr Bremner will be able to obtain results surpassing those in his present series, satisfactory though these already are, merely by avoiding anæsthesia

London, W 1 **JAMES CYRIAX**

SIR,—Mr Bremner's article is, I think, the clearest and least biased article on the subject that I have read

Being unprejudiced he inevitably arrives at the conclusion that manipulation is a good thing All right, let the manipulation be carefully applied and the manœuvres thoroughly studied, then, Sir, he can probably dispense with the anæsthetic and possibly eliminate one of the "variables"

London, W 1 **W HARGRAVE-WILSON**

EFFECTS OF CERTAIN PROTEIN FOODS ON BLOOD-SUGAR LEVELS AND GLUCOSE TOLERANCE

SIR,—When we reported our results[1] (Aug 17), we had also observed that two hyperglycæmic patients showed considerable improvement when their diet contained, in addition to their normal complement of rice or chappatis or bread, a greater proportion of fish, egg, or lean meat but little or no fatty food, such as bacon and pork However, as no quantitative data on the calorie intake of these patients had been recorded, it was thought that these observations could wait until we had occasion to publish in detail the results of our further study, now in progress, on the effects of ingesting different types of proteins (of both animal and vegetable origin) and their hydrolysates on blood-sugar and glucose-tolerance in healthy and hyperglycæmic subjects But in view of the interesting letter by Dr Bicknell[2] it seems appropriate to record our findings with animal-protein diets

OSTEITIS PUBIS AFTER INGUINAL HERNIORRHAPHY

SIR,—May I congratulate Mr Le Vay and Mr Borman on their report (Dec 21) I would like to add to their cases a personal one that occurred in a series of over five hundred herniæ in men over 50 years of age

The patient was a man of 50 and he evinced the same symptoms of backache and pubic and perineal pain Before the diagnosis was made he was seen by a rheumatologist, a physician, a neurologist, and my friend Mr E W Riches, who diagnosed the condition he was called in because of a suspicious hardness of the prostate (? carcinoma)

Although in this patient there was no apparent infection, I think the underlying cause is a subclinical infection about the stitch (in this case no 50 linen thread), which passes into the periosteum of the pubic tubercle, with a spreading reaction in the pubic vessels He completely recovered in 18 months His X-rays were identical with those shown by Le Vay and Borman It is a baffling and tiresome complication

London, W 1
HAROLD DODD

SIR,—Mr Le Vay and Mr Borman[3] should be congratulated on immediately recognising the condition of osteitis pubis as their "second and third post-herniorrhaphy patients tottered into the orthopædic clinic"

Osteitis pubis was first described as a postoperative complication by Legueu and Rochet in 1923[4] and fully dealt with by Edwin Beer[5] [6] in 1924 and 1928 Many papers have appeared on osteitis pubis since, but not very much has been added to Beer's original postulate that most probably trauma and infection were the main factors responsible for the development of this complication

I drew attention to this condition in 1947[7] after I had diagnosed osteitis pubis in one of my patients, who was shown at the meeting of the Middlesex County Medical Society on June 9, 1945 Although not generally known then, the syndrome later did become well recognised in the British Isles, especially among urologists, as a complication following operations on the bladder and prostate As I observed in 1947, typical instances of osteitis pubis had already been reported following operations for hernia and further observations would prove that this complication was not rare

It was interesting to read again about the failure to influence the course of this condition by any active treatment including cortisone I have had the opportunity of trying cortisone and found that it did relieve the pain (previously quite unaffected by large doses of morphine) and allowed the patient free movement, but the injections had to be discontinued on account of prohibitive side-effects

In my own personal series of 300 suprapubic bladder operations, chiefly prostatectomies, on which I reported in 1947, osteitis pubis arose in 10 patients (3%) Looking back, I now believe that this was most probably due to a flaw in my technique, as all lower abdominal operations infringing the integrity of the pubic periosteum would appear to be liable to the complication of osteitis pubis

London, W 1

RADIATION FURTHER WARNINGS

SIR,—The leading articles and annotations of *The Lancet* used to be, and should still be, like Cæsar's wife It is true they are difficult to write They review data published in the world's scientific and medical press and often give guidance to the reader in the form of critical editorial opinion The journal and its editors cannot be blamed for drawing the "wrong" conclusion or holding "wrong" opinions, but they can be castigated for misreporting the data

Recently I have been taken to task by my colleagues overseas for permitting to pass without comment a leading article in *The Lancet* referring to radiobiological work in which the data were wrongly reported It was left to workers in the Netherlands to voice objection in a letter to *The Lancet* Unhappily there is now a recurrence in the annotation of Dec 28 I must beg leave to point out the error

After summarising some recent publications, in fair but somewhat lurid form, the annotation works round to genetic damage produced by radiation, it then becomes misleading To Glass[1] is attributed the statement "Since mutations are caused by the fracture of a chromosome followed by reunion of the broken ends in a new pattern, at least two fractures are needed for a mutation, that is why the incidence of mutations increases as the square (or some higher power) of the dose" In fact Glass was very careful to discriminate between *chromosomal* mutations such as the above and *point* mutations I quote from his article

> "Inasmuch as the chromosomal mutations are produced chiefly by high doses, and in those very cells that are most readily eliminated through the production of the well-known temporary sterilisation of the male after acute doses of radiation, there is relatively little genetic damage to be expected from them
>
> "Of chief importance, then, are the point mutations, in which the lesions of the hereditary material are submicroscopic in size
>
> "All existing genetic evidence indicates that the frequency of point mutations increases linearly with the radiation dosage"

Everything that I have quoted from Glass is standard teaching based on scientific data It has all been said many times before and is to be found in the report of the Medical Research Council's committee[2] and in the report of the National Academy of Sciences[3] It is true that Glass interprets the established data in a rather more pessimistic fashion than either of the national committees, like any thinking scientist, he is fully entitled to his personal opinion It is not right, however, for you to take Glass' opinions and hang them on to distortion of the facts

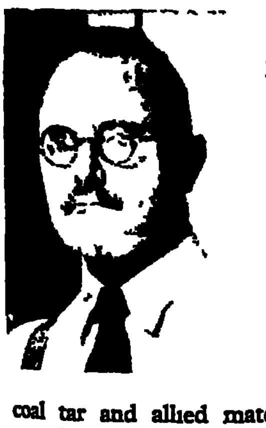
Obituary

ERNEST LAURENCE KENNAWAY

Kt, M.A, D M Oxon, D Sc Lond, F R C.P, F R S

Sir Ernest Kennaway, who died on Jan 1 at the age of 76, had the great gift of scientific curiosity in such degree that neither disabling illness nor age could turn him from his purposes The achievements of his able mind included the first demonstration, in 1930, that cancer can be produced by a pure chemical compound, and through many years he proved a leader in the new study of carcinogenesis



Son of L J Kennaway of Exeter, he distinguished himself as student and graduate successively at University College, London, at New College, Oxford, at the Middlesex Hospital, and at Guy's Hospital, where for some years he demonstrated physiology From the first he was interested chiefly in the biochemical side of medicine, and he did much work on purine metabolism and on acetonuria From Guy's he moved back to The Middlesex as chemical pathologist, and thence to the Cancer Hospital Already in the early 1920s he recognised that the cancer-producing properties of coal tar and allied materials implied the presence of specific chemical individuals having this property, and he undertook a series of painstaking researches, unaided except by a technician whom he trained, in which he examined tar fractions and a large number of the known constituents of tar

From his first paper, published in 1924, an important conclusion was that the cancer-producing substance was present in a fraction of pitch distillate which came over above 500 C This work was followed by studies of artificial cancer-producing tars formed by the pyrolysis of acetylene, isoprene, cholesterol, and other organic materials, and then of the very potent high-boiling fractions of the mixture of hydrocarbons formed by the action of aluminium chloride on tetrahydronaphthalene Although Kennaway himself seemed not to appreciate the fact, this pioneer work showed fairly conclusively that the materials he sought were complex hydrocarbons, probably of aromatic type

These efforts were presently supplemented by those of physicists, chemists, and a biochemist in the team which he assembled, and had their culmination in 1932 in the isolation from coal-tar pitch of a potent carcinogenic hydrocarbon which was shown by synthesis to be the hitherto unknown 3 4-benzpyrene Kennaway's own general account of these researches was published in 1955 A parallel line of investigation, based on the fluorescence spectroscopic studies of Mayneord and Hieger, led to recognition of a considerable group of potent carcinogenic hydrocarbons, all of them prepared synthetically The carcinogenic activity of the first of these, 1 2 5 5-dibenzanthracene, was described by Kennaway in 1930, although, through a chemical error which Dr J W Cook was able to correct, the compound was wrongly described in his paper as 1 2 7 8-dibenzanthracene

A detailed account of the biological properties of these hydrocarbons is given in a series of papers in the *Proceedings of the Royal Society* with the general title of the Production of Cancer by Pure Hydrocarbons A brief summary of these and later developments by Dr Cook appeared in our columns last February

Perhaps equally important were Kennaway's epidemiological studies, carried out with Lady Kennaway, who also assisted in his experimental researches

This very laborious work involved the examination of tens of thousands of death certificates and illustrates Kennaway's flair for amassing, classifying, and correlating data Such studies have aimed at correlating the numbers of deaths from cancer, in various years, with sites of the disease and occupations, environments, and other circumstances of the victims The Kennaways' 1936 publication, a Study of the Incidence of Cancer of the Lung and the Larynx, was one of the earliest papers to focus attention on the rising incidence of lung cancer, especially in men It was followed by two others in the same field, in 1947 and 1951, and in the latter year Kennaway also published an illuminating survey, Cancer of the Lung in Relation to Tobacco, in which he followed up an earlier experimental study of the arsenic content of tobacco from various sources

Of the man who achieved this big output of valuable work, some idea is given by the following extracts from tributes by his friends

* * *

Sir Ernest Kennaway was one of the great men of his generation He was essentially a shy man and in some respects unduly modest He shunned publicity and was perhaps little known outside the immediate circle of his medical and scientific colleagues Until his latter years he declined to take part in public discussion in any form, even at small intimate scientific gatherings This was probably due in part to the handicap of the affliction from which he suffered for more than thirty years, but which he was able largely to overcome by dogged determination and sheer force of character He was a man of high principles and would pursue any course in which he believed with the ardent zeal of a crusader He would never take " no " for an answer, and compromise was no part of his make-up None, however eminent or exalted, were spared the lash of his tongue or the pungency of his pen when he disapproved of their actions or their neglect to act Himself very painstaking and methodical, he had no patience with careless or slipshod work in any form, and was quick to point out inaccuracies and to rebuke their authors One of his last remarks to me, a month before his death, was " Well, although I can no longer walk, I can still bite "

But the picture of a stern, forbidding personality would be unjust to his memory Although Kennaway was not a man with whom people took liberties, he was nevertheless a friendly and hospitable man, and in the manifestation of these qualities he was greatly helped by the grace and charm of Lady Kennaway, to whose care and support he owed much In his own way he had a keen sense of humour He was particularly kind and generous to his younger colleagues, many of whom had good cause to be very grateful to him for his inspiring encouragement and for the stimulating enthusiasm with which he took an interest in their work He displayed unbounded confidence in their ability to overcome their difficulties and great delight when they succeeded

Sir Ernest was no narrow specialist He had received a broad scientific training in addition to his medical training and was also a man of wide general culture In his latter years he took some interest in religious beliefs and religious customs, but his views were rather bigoted and this was not one of his happiest pursuits He had a graphic style and his published accounts of his travels—to Iceland, to Norway, and to the United States, for example—were full of factual information of great value and punctuated with entertaining asides and comments on details which would have escaped the notice of most people At one time he was interested in the cinema, and his article, Zadigism and the Cinema, published in *St Bartholomew's Hospital Journal* in 1949, is an amusing commentary, which shows some of his breadth of knowledge, on the incongruities as regards both time and environment of some of the films he had seen

For about forty years Kennaway had dedicated himself to cancer research, and no-one has made greater contributions to it than he This has been generally acknowledged throughout the world His work is characterised not only by the genius which comes of an infinite capacity for taking pains but also by an inspired faith in its methods and its outcome That he was able to make the right approach was due in no small measure to his detailed knowledge of various fields of pathology, chemistry, and biochemistry His general appreciation of several branches of science enabled him to guide and direct the efforts of a team of experts, each of whom was enabled to bring his own specialised knowledge and experience to bear on the problems under investigation

Though it is probably too early to make a final assessment of the importance of this work, it has completely reorientated cancer research Kennaway himself wrote of it in 1945 with characteristic understatement "The very numerous carcinogenic compounds which have been discovered in the last 15 years have served, even if they have done nothing else, to dispel some of the rather hopeless mystery which used to surround the whole subject of the ætiology of cancer" It is to be hoped that a collection of his more important papers may yet be reprinted They would serve as models for many young people embarking on a research career J W C

Others, who knew Sir Ernest earlier than I, will describe his pioneer work, which all respect and which many of us would do well to reread at intervals I met him first during the last war, when on the eve of enlistment I came to ask him whether a bit of unfinished work was worth recording he made me publish it Later I found myself on the fringe of his wide zone of interest in tobacco carcinogenesis, and undertook some tests in this field He had a remarkable way of showing his interest in one's work, which often seemed to give it an importance one had not thought it possessed I feel an affectionate gratitude for the kindly and persistent efforts he made, despite illness, during recent years to stimulate and encourage and guide those whom he believed could help in the study of lung cancer M H S

During the last years of his life Sir Ernest suffered from at least four major conditions, any one of which would have been sufficient to induce most other men to cease active work But though his body was infirm his mind retained an extraordinary vigour It was characteristic that during his last illness, when he knew that he was seriously ill, he wrote an article on nursing from the patient's point of view, and continued to plan for the future, only two days before his death he telephoned a friend to inquire about the chemical peculiarities of the fuel used to smoke fish in Iceland, which process he thought might contribute to the high incidence of cancer of the stomach there

In later years his interest centred particularly on the epidemiological approach to the study of cancer, and he published papers on the epidemiology of cancer of the larynx, lung, penis, and cervix uteri But he was never content merely to discover differences in incidence, his object was always to find out what lay behind them and how they were produced No aspect of human behaviour was too trivial for his attention, and he allowed no taboos to stand in his way Any subject was fit for speculation, but he distinguished himself from so many others by immediately setting out to obtain quantitative data which would allow his speculations to be tested

He was not an easy man to get on with and took offence at times, where none was intended This, however, nearly always arose because of his inability to appreciate how much he was honoured He was in reality a humble man and always assumed that his contributions and opinions were unwanted and would be ignored He was at his best in contact with young workers, whom he treated as his equals, and he was as ready to learn from them as they were from him To those who worked along with him he showed a lively sense of humour and a warm humanity, to them he was a source of constant inspiration and a model of the devoted inquirer after truth

R D

HAROLD GEORGE BEDFORD RUSSELL

M.A , B Chir Cantab , F R C S

Mr H G Bedford Russell, consulting surgeon to the ear, nose, and throat department of St Bartholomew's Hospital, London, died on Dec 30 at his home in Oxfordshire

He was born at Geelong, Victoria, in 1886 and went to school in Australia He came to this country to study medicine at Sidney Sussex College, Cambridge, and at St Bartholomew's Hospital, qualifying in 1911 During the 1914–18 war he served in France with the rank of major, and acted as D A D M S of IX Corps For his work he was mentioned in despatches and awarded the Croix de Guerre

In 1919, after he was demobilised, he took the F R C S and was appointed chief assistant to the ear department at Barts under Ernest West and Sydney Scott After West's retirement the departments were regrouped and Bedford Russell moved to the throat department, then a separate unit under Mr Douglas Harmer and Frank Rose Bedford Russell was closely associated with Mr Harmer in his assessment of the value of radiotherapy in cancer of the upper air-passages (later published as the Semon lecture of 1931) Much of the analysis of results and data was entrusted to Russell

Russell also joined the staff of the Hospital for Diseases of the Throat in Golden Square, at first as registrar, later becoming assistant surgeon, surgeon, and dean He worked for some years at the Facial Injuries Hospital at Sidcup at the time when Sir Harold Gillies and Prof Pomfret Kilner were laying the foundations of modern plastic surgery In 1928 he was appointed assistant surgeon to the throat department at Barts, and two years later he succeeded Frank Rose as head of the department

Bedford Russell worked extremely hard at his hospitals, quickly built up a large private practice, and yet was an active member of a number of medical societies From 1932 to 1934 he was secretary of the section of laryngology of the Royal Society of Medicine, and he arranged for Ferris Smith to visit this country and demonstrate to his colleagues here his external operation for chronic ethmoiditis

Of Bedford Russell's work as a surgeon and his interests as a man F C O writes

Bedford Russell was enterprising and energetic in everything he did In his professional life his early efforts were concentrated on the throat, but later his attention became diverted to the paranasal sinuses He took up the study of infection of the sinuses with customary zeal and developed the operative technique to the most complete drainage and exenteration possible He became interested in the effect of sinus infection on the mind and gave many years to the study and investigation of the relation between sinus disease and mental disorders He was associated with a number of institutions and societies concerned with mental diseases and wrote many papers on the subject

He was a keen tennis-player, putting his characteristic dynamic energy into the game and deriving equally characteristic enjoyment from it He took up skiing with the same enthusiasm, visited Murren every year, and gave the Bedford Russell cup for which an annual competition is held He derived the greatest exhilaration from the weeks he spent each year in Switzerland He took to country life, with its attendant sports and responsibilities, with the usual energy and drive and rented and farmed a number of estates in various parts of the

Home Counties The part of squire was one that afforded him great satisfaction.

Mr Bedford Russell married in 1928 Lilian, daughter of the late Harold Longmore-Mavius She survives him with their two sons

HAROLD PERCY WALLER BARROW

C.B., C.M.G., D.S.O., O.B.E., M.R.C.S., D.P.H., D.T.M.

Major-General Barrow, who died on Dec. 20 at the age of 81, was director of hygiene at the War Office from 1924 till 1930 and colonel commandant of the Royal Army Medical Corps from 1941 to 1946

He was born at Madras, the son of Colonel H J Waller Barrow, A.M.S After qualifying from Guy's Hospital in 1898 he became a surgeon probationer, and he received his commission in the R.A.M.C. the following year. He served in South Africa from 1900 to 1902 and later he was posted to the Punjab and to Jamaica. In the first world war, after a time as deputy assistant director-general at the War Office, he served in France as A.D.M.S of a division and was awarded the D.S.O in 1918 After the war he returned to India as deputy director of hygiene and pathology at Army Headquarters, and in 1924 he took up his last Army appointment as director of hygiene at the War Office.

After he retired in 1930 he became health officer in Antigua and a member of the Federal Executive Council of the Leeward Islands and Antigua until 1933 Later he settled at Epsom where his many activities included work as a commissioner of the Royal Hospital, Chelsea, and as a member of the committee of the Royal Patriotic Fund Corporation. Some years ago he moved to Brockenhurst, and he died at his home there. In 1901 he had married Miss Estella Hertog of The Hague, by whom he had two sons and a daughter

A colleague writes that many who as young officers served under Boy Barrow will remember "his kindly interest and the hospitality which he and his wife dispensed so generously and so enjoyably."

WILLIAM JAMES FENTON

M.D. Camb., F.R.C.P

Dr Fenton, consulting physician to the Brompton Hospital and Charing Cross Hospital, died in London on Dec. 24 at the age of 88

He was educated at Leamington College School, Caius College, Cambridge, and St. George's Hospital. After qualifying in 1894 he held several resident appointments at St. George's, and he seemed set for a place on its staff. But he was unlucky, for, when he reached the age when promotion could be expected, no vacancy seemed likely for some time. Fenton accordingly applied for and obtained an appointment at Charing Cross Hospital as an assistant physician. Shortly afterwards a death vacancy occurred at St. George's, but Fenton felt that as he had thrown in his lot with Charing Cross he could not seek election to St. George's, though it was a great disappointment. Soon afterwards he was elected to the staff of the Brompton Hospital, and he became a fellow of the Royal College of Physicians in 1907.

The National Health Insurance Act of 1911 called for the setting up of a tuberculosis dispensary for Chelsea, and when it was decided that this should be located at Brompton, Fenton became medical officer in charge. For some years he was dean of Charing Cross Hospital Medical School, and later he became dean of the Brompton Hospital School. He retired from the staff at Charing Cross in 1933, and remained till 1939 at Brompton, where a member of the staff at that time need not retire until he had been a full physician for twenty years

Fenton was one of those who was a consultant in diseases of the chest before chest X-rays had shown their worth; but he was quick to appreciate their value as soon as technical advances produced satisfactory plates, and in *Diseases of the Chest* (1930) with his co-author, the late L. S. T. Burrell, he suggested that the importance of clinical signs could be exaggerated in view of the precision of modern methods of diagnosis. Of Fenton as a colleague and a friend, F. H. Y. writes

He was a capable and careful physician, though his was not an original mind. His work at his hospitals was of a high standard, and he was popular with his patients because of his interest in their welfare. His chief hobby was photography, and after his retirement he presented to the Brompton Hospital Medical School two volumes of beautifully reproduced photographs of X-rays of obscure diseases of the chest. Architectural photography was another of his interests when on holiday In the early part of the war most of his time was spent taking photographs for the National Buildings Records He was keenly interested in music, and as a young man was a competent performer on the violin. Fenton was not easy to get to know, and few of his colleagues knew him except through his hospital work. Those who did know him, however, found a kindly and perceptive man.

Dr Fenton's wife died in 1930, and one of his sons was killed on active service during the late war. He is survived by a daughter and a second son.

EDITH MAY HALL

M.D. Lond., F.R.C.S., F.R.C.O.G

Miss Edith Hall, gynaecologist and obstetrician to the South London Hospital for Women, died at her home in Hampstead on Dec. 26 at the age of 61.

She graduated M.B. from the London School of Medicine for Women in 1920, and on taking the M.D. in 1922 won the university gold medal in midwifery and gynaecology. In 1923 she was appointed an assistant in the obstetrical and gynaecological unit at the Royal Free Hospital.

She also joined the staffs of the Marie Curie Hospital when it was first opened in 1925, and of the London Homoeopathic Hospital. In 1935 she became assistant surgeon, and later full surgeon, to the South London Hospital for Women. For many years she also held the post of consultant gynaecologist and obstetrician to the London County Council hospitals service.

Since 1949 ill health had gradually forced her to give up much of her hospital work, but she remained on the staffs of the London Homoeopathic Hospital and the Marie Curie Hospital until her death. How much she still found time for is shown by the following tribute from O R.

Edith Hall's success was due to natural ability, combined with a phenomenal capacity for sheer hard work, and a retentive memory. She also developed at an early age the maturity of mind and character and the sense of responsibility which made her such a valuable member of her profession. She never had a great fund of physical energy, although she was able to stand for long hours in the operating-theatre. Her hospital appointments entailed many regular sessions and a considerable amount of emergency work. She had long distances to cover by car, and always drove herself, and any time left over must have been fully occupied with committees and with her private patients. Despite all these demands she never allowed herself to be hurried over her professional work; she was in fact a slow worker, spending a considerable time in talking to her patients and allowing them to talk to her, thus making an effort to get to the bottom of their difficulties and troubles. She had an exceptionally amiable temperament, always appeared calm and unruffled. Completely [illegible] her innate charm and courtesy of manner never [illegible] always sincere. She had a sense of humour, and an [illegible] character, even when she [illegible] herself, her standards were high and she never [illegible] what she considered right Her judgment of people could be penetrating and acute, though she looked on the failings of others with a slightly humorous and kindly tolerance, and she never spoke unkindly about anyone

Though she had considerable strength of character and held decided opinions, she was always conciliatory, and on those occasions when she felt very strongly about anything, especially where the running of the hospital or the welfare of the patients was concerned, she could be tenacious to the point of obstinacy, nevertheless she always listened with courtesy to the views of others, and often managed to get what she wanted by tactful persuasion

In spite of her busy life, she always found time to keep in touch with her old house-surgeons and registrars, and she took a great interest in their careers Many of them are now settled abroad, and they always found a welcome at her house when they came back to London She had little time for hobbies, but was interested in archæology and architecture, and spent many of her holidays travelling abroad with her sister It is sad that her death should have come as she was looking forward to a peaceful retirement, with the opportunity for doing all those things for which she had never before had time

THOMAS HERBERT CECIL BENIANS

F R C S

Mr T H C Benians, honorary consulting pathologist to the Prince of Wales's General Hospital and to the Tottenham Group of Hospitals, died on Jan 1 at the age of 75

For a short time after qualifying from the London Hospital in 1907 he worked in South Africa and Rhodesia In 1914 he was appointed pathologist to the Prince of Wales's General Hospital and later he also became part-time pathologist at the North Middlesex Hospital, where during the late war he did much to build up the blood-transfusion service Soon after the war he gave up this post to become whole-time pathologist to the Prince of Wales's General Hospital and, within a short time, to the Tottenham Hospital Group under the National Health Service After he retired in 1951, he continued to work sometimes as a locum at other hospitals, and when not thus engaged continued his own research in his old laboratory at the Prince of Wales's General Hospital, where he was working until a few months ago

The North London Postgraduate Medical Institute owes much to the work which Benians put into the old North East London Postgraduate Medical College, of which he was for many years the vice-dean He was responsible for drawing the North Middlesex Hospital, and later Chase Farm Hospital, into the scheme, and on this amalgamation the present institute was founded The pathological museums of the institute are formed around the nucleus that was collected by Benians and his staff

Of his position and friendships at the hospital B H J writes

Tommy Benians was a popular figure at the Prince of Wales's General Hospital, and generations of housemen came to regard him as a father confessor who would give sound advice on pathology and on many other matters not necessarily related to professional work Such phrases as "You surprise me", "Now that's interesting", and "You must tell me more" when associated with a merry twinkle from his blue eyes encouraged the most bashful young man and conversation would flow freely Over lunch he would often recount little incidents with great enjoyment, but never with malice and never in a manner to cause any hurt He never claimed to be a clinician, but his advice on further investigations that might prove fruitful was often sought and often solved a clinical problem On one occasion he listened to a junior house-physician's account of a patient brought to the casualty department who died almost within minutes, and Tommy said, "Now that's interesting you will find that he has a rupture of the aorta into the pericardium", and the autopsy proved the correctness of his diagnosis

Gardening and growing flowers gave him great pleasure, and when he lived in a flat during his latter years his small allotment was a continual joy to him He was also a keen amateur artist, and of this interest P H M-B relates

In recent years I knew Benians more through his paintings than through his work He was a member of the Medical Art Society and besides attending our evening sessions he exhibited from time to time some of his original and quizzical compositions It was always good to meet him, for he possessed an unusual and refreshing turn of mind, and he preserved the same lively interest and whimsical turn of humour as in our student days at the London Hospital

Mr Benians leaves a widow, two sons, and a daughter

JOSEPH LENNOX PAWAN

M B E, M B Edin, D P H

Dr Pawan, formerly bacteriologist and pathologist to the Government of Trinidad and Tobago, died at his home at Port of Spain on Nov 3 at the age of 70

He graduated M B from the University of Edinburgh in 1912, and after postgraduate work at the Pasteur Institute, Paris, and in Germany, he returned to the West Indies and took up the appointment of Government bacteriologist which he held for over a quarter of a century He published papers on serum-calcium levels, pulmonary tuberculosis, sleeping-sickness, and the bacteriology of water-supplies and food-poisoning in the tropics, but his most important study was his articles on the transmission of paralytic rabies by the vampire bat, and he was appointed M B E for his investigations into the pathology and histology of this disease In 1954, he visited America as a consultant on rabies to the United States Government He was invited to become joint chairman of the Rabies Committee of the World Health Organisation, but ill health forced him to decline this invitation He is survived by his widow, one son, and two daughters

Sir THOMAS DUNHILL

A P B writes

Thomas Dunhill was a brilliant surgeon and essentially kind, two attributes not always met with together The two most beautiful sights I have witnessed in surgery were the late Lord Moynihan operating in the abdomen and Sir Thomas on the exophthalmic thyroid There was no fluster, the silence was broken by the click of the forceps, though the former might discuss the latest novel Each was gentleness personified Lord Moynihan used to teach "Every pull is a pain" But the most impressive feature was the absence of blood despite the vascularity of the organs

Appointments

GRIFFITH, D H S, L.R C P E, D P H, D I H M O H, Guisborough, Loftus, Skelton, and Brotton, Yorkshire

SACKWOOD, MARK, M B Lond, D OBST senior assistant M O H (maternal and child welfare), Middlesbrough

SHEPHARD, R H, M D Lond, F R C.S part-time consultant neurosurgeon, Derby group of hospitals

Births, Marriages, and Deaths

BIRTHS

DAY—On Jan 3, to Sonia, wife of Dr F M Day—a daughter, a sister for Carolyn

DEATHS

BENIANS—On Jan 1, at the Prince of Wales's General Hospital, London, N 15, Thomas Herbert Cecil Benians, F R C.S, aged 75

Notes and News

NEW LOOK FOR LAMBETH

"WHEN Hitler has finished bombing our cities," wrote Herbert Read during the war, "let the demolition squads complete the good work" The squads will soon be at work again on the south bank of the Thames, for the governors of St. Thomas' Hospital are planning their share of the reconstruction. The hospital was badly hit by bombing, by the end of the war seven of its thirty wards were destroyed and fourteen unusable, and it has lately been found that the buildings remaining are so unsound that they are not worth renovating The board have a plan which entails the diversion of Lambeth Palace Road further from the river, thus doubling the area of the hospital site They have provided a block of flats, now nearing completion, to house those whose homes will be demolished

A completely new building is to be erected, in stages to enable the present hospital to function during the building The main block of the new hospital, 120 yards from the river, will be 11 storeys high, containing 32 wards (827 beds) in 8 storeys, a 4-storey building, connected to it and lying between the main block and the road, will house outpatient departments and operating-theatres Other buildings, some of them in the space between the main block and the river, will provide accommodation for nurses, residents, and students, and (it is hoped) house the medical school The main block will be about 140 feet high, and the buildings nearer the river about 80 feet—the height of the present structure Most of the space between wards and river will be open, allowing excellent views The construction will be of concrete, but details of finish are not yet decided. Communication will be vertical by means of 4 towers housing lifts and stairs, the fifth and eighth floors (which will house laboratories) and the ground floor will provide horizontal communication The wards are designed in accordance with principles enunciated by the Nuffield Provincial Hospitals Trust, each will have a central entrance and service rooms

The Minister of Health has provisionally approved the scheme, subject to agreement on the scale of residential accommodation, it is being submitted to the Royal Fine Arts Commission and to the London County Council (the planning authority) Each of the four stages of building is estimated to take about 2$^1/_2$ years, and the total cost of the hospital (excluding the medical school and the road diversion) is put at about £7$^1/_2$ million It is hoped that building may begin some time next year

TELEVISION PROGRAMME ON CANCER

CANCER research was the subject of a recent B B C television programme An anonymous surgeon, who admitted to eradicating rather than curing cancer, introduced several research-workers Prof J F Danielli dealt with the question "what is cancer?" and showed cinemicrographic films of normal and cancerous cells dividing Dr R J C Harris described carcinogens, and Prof Geoffrey Hadfield discussed the role of endocrines in breast malignancy Dr L H Gray showed a film of dividing cells, revealing clearly the influence of radiation on the chromosomes Finally, methods were shown of testing chemicals that arrest malignant growth Summing up, the chairman emphasised that though no cure had been discovered, research was continuing along several lines, and the final answer might come from any of them

The symposium gave a good impression of the vigorous approach to the problem by several routes, and conveyed well the feeling that the chances of finding a cure were hopeful rather than encouraging at present There was no attempt to talk down to the audience and the excellent animated diagrams and film clearly illustrated the points being explained The random use of the terms "cancer", "carcinoma", and "malignancy" may have been confusing to some viewers The production (by James McCloy) was carefully planned and well presented

CARE OF DRUG ADDICTS

A STUDY group of the World Health Organisation has issued a report[1] on drug addiction It is concerned solely with addiction to opium (and its derivatives and synthetic substitutes) and to cannabis derivatives It deals with treatment, and considers prevention only as regards relapses

Addicts are classified according to their amenability to treatment Easiest to treat (often by mass methods) are those who fall into addiction during some temporary stress—e g, hunger, a painful illness, or the depressive phase of cyclothymia Harder to treat successfully are those with a basically pathological personality There is usually immaturity of character development and a desire to live only in the present or a destructive or self-destructive tendency, besides a lack of capacity for dealing with stress The causes may be found in emotional deprivation, lack of a parental figure to form a proper ideal (both common in broken homes), or over-indulgence during childhood, or an unrealistic attitude with standards differing from those of the patient's basic subculture Patients may, however, move from group to group

The fundamental need in treatment is effective control of the drugs concerned The addict must be regarded as a patient For those who do not respond easily to simple or mass methods, treatment will be psychotherapeutic and not essentially different from psychotherapy in other personality disorders It should aim at giving the patient more insight, understanding of the unreal character of his neurotic fears, and a better judgment of situations Maintenance of addiction is not treatment and should be reserved for special circumstances, withdrawal is important though only a part of treatment It is distressing and must be done with skill, speed, and humanity, and must be fully discussed with the patient It may be gradual or abrupt, supportive treatment, with sedatives and perhaps intravenous infusions, may be given, and in some cases electric or insulin shock therapy The methadone substitution technique[2] is recommended, but sedatives and tranquillisers "often make the withdrawal unnecessarily dangerous"

The continued-treatment stage, which aims at reablement of the patient till he can withstand the normal stress of life without using drugs, is time-consuming but the most important Withdrawal may be so unrewarding that the patient fails to continue treatment, or may lead to overconfidence Over two or three years the relapse-rate is high, and the patient needs support from his physician and friends and from social agencies The most effective method in most countries is civil commitment to medical care, with a gradual return to society through open wards and halfway houses

The report ends by calling for further studies of the prevalence of addiction in various countries, for diagnostic tools such as a urine test for the drugs concerned, and for extensive life-histories of addicts Annexes consider the ætiology of addiction and the legal framework of treatment in various countries

---

Whitley Dispute

On Jan 2 representatives of administrative and clerical workers in the National Health Service decided to end the ban on overtime which began on Nov 18 as a protest against the Minister of Health's refusal to approve a 3% pay increase recommended by the Whitley Council for these workers (*Times*, Jan 3) A fresh claim for a 5% increase is being submitted to the council, if the management side reject this claim, it could then be referred to arbitration by the Industrial court

Royal Society of Health

On Wednesday, Jan 15, at 2 30 P M at 90, Buckingham Palace Road, London, S W 1, Dr W S C Copeman, chairman of the Empire Rheumatism Council, will speak on the problem of rheumatic diseases

---

British Association of Allergists

The annual general meeting of this association will be held at 11 A M on Saturday, Jan 18 at 1, Wimpole Street, London, W 1

Canadian Poliomyelitis Vaccine

The first consignment of Canadian Salk vaccine arrived by air in Manchester last Saturday, on its way to the Liverpool headquarters of Evans Medical Supplies, who are handling the vaccine in this country (*Times*, Jan 6) This batch contains four tons, and altogether 5 million doses have been ordered

Laboratory Animals Bureau Congress

Sir Solly Zuckerman will open this two-day congress at 9 30 A M on Monday, March 24, at the Medical School of the University of Birmingham Further particulars may be had from the bureau, M R C Laboratories, Holly Hill, Hampstead, London, N W 3

Anglo-French Exchange Bursaries

Short-term grants for work in France are offered again this year to British doctors and medical research workers by the Institut National d'Hygiène, Paris Application forms can be had from Dr G W Wolstenholme, Ciba Foundation, 41, Portland Place, London, W 1 The closing date for application is Feb 2

Royal Commission on Remuneration

The Royal Commission on Doctors' and Dentists' Remuneration will hold public hearings on Thursday and Friday, Jan 16 and 17, at 11 15 A M, at Church House, Great Smith Street, London, S W 1 Representatives of the Medical Practitioners' Union have been invited to attend on Jan 16, and Lord Moran has been invited to attend on Jan 17

Conference on Work Study

This conference, convened by the British Institute of Management, will be held in Caxton Hall, London, S W 1, on Feb 6

The programme will include a talk by Mr R P MacMahon, deputy house-governor of the Westminster Hospital, on work study and the hospital service Full particulars may be had from the press officer, Management House, 80, Fetter Lane, E C 4

The Royal Society

Sir Lindor Brown and Sir Charles Dodds have been appointed vice-presidents of the society for 1957–58

Awards under the Society and the Nuffield Foundation Commonwealth bursaries scheme have been made to Dr A J Buller, senior lecturer in physiology, St Thomas's Hospital Medical School, London, and Dr W P U Jackson, senior lecturer in medicine, University of Cape Town

Roehampton Courses on Artificial Limbs

Courses on artificial limbs and rehabilitation after amputation, for consultants and senior registrars in orthopædic surgery or physical medicine, are now held at Roehampton in March and October The next course for orthopædic surgeons will be from March 24 to 28 inclusive, and the next for specialists in physical medicine on March 5 and 6 Those interested should apply to the Principal Medical Officer, Artificial Limbs and Appliances Centre, Roehampton House, London, S W 15

Steroid Reference Collection

Part of the Medical Research Council's Steroid Reference Collection, formerly kept at the National Institute of Medical Research, has been moved to the Postgraduate Medical School of London

All requests for compounds in the collection should now be addressed to Dr W Klyne at the School, Ducane Road, W 12 As a result of generous gifts from two industrial firms larger supplies of œstriol and 16-epi-œstriol (Organon Laboratories) and very limited supplies of racemic aldosterone (Ciba AG, Basle) are now available, these materials are intended for chemical reference purposes, and not for clinical work.

Adelaide Hospital, Dublin

An association of old students of this hospital is bei formed All old students are asked to write giving their name and addresses to the secretary, Association of Old Adelaid Students, Adelaide Hospital, Peter Street, Dublin

Major-General F C Hilton-Sergeant has succeeded Air Commodore H A Hewat as medical adviser to the British Red Cross Society

Prof W C W Nixon is to visit the United States in February to attend the annual session of the Obstetrical and Gynecological Assembly of Southern California at Los Angeles

Corrigenda The new medical dictionary which the late Dr L E Napier was preparing is to be published by the Caxton Publishing Company, Ltd, and not the Caxton Press as stated in our obituary (Dec 28, p 1343)

The Ankle-jerk in Early Hemiplegia—In Dr Buller's paper (Dec 21, p 1262) the tracings in the lower part of fig 4 were wrongly labelled The right-hand tracing recorded the left ankle jerk and the left-hand tracing the right jerk

ÆTIOLOGY OF PRE-ECLAMPTIC TOXÆMIA AND ECLAMPSIA

FACT AND THEORY *

F J Browne

M D Aberd, D Sc Edin, F.R.C S E, F R C O G

EMERITUS PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE NIVERSITY OF LONDON, CONSULTING OBSTETRIC SURGEON, UNIVERSITY COLLEGE HOSPITAL, LONDON

A DISCUSSION at the Royal Society of Medicine, London, n the Ætiology of Pre-eclampsia (*Proceedings of the Royal Society of Medicine* 1957), though of great interest nd presenting new data bearing on pathogenesis, seemed o fail in its presentation of all the facts as well as in its ack of any precise conclusions regarding the ætiology of pre-eclamptic toxæmia and eclampsia

It has long seemed to me that, thanks to the researches n Great Britain, the United States, and elsewhere, specially in the past ten years, we now have all the essenial facts bearing on the ætiology of eclampsia, and that hey resemble the pieces of a jig-saw puzzle and only need o be assembled in proper sequence to provide an acceptble explanation of eclampsia, including its onset two r three days after delivery

Any satisfactory explanation of the ætiology of eclampsia must explain (1) why it occurs only in association with pregnancy and only in man, (2) its preference for first pregnancies (75% of cases), (3) why it sometimes occurs n pregnancy with hydatidiform mole and no fœtus, and that very early in pregnancy (say from the 12th to the 16th weeks), (4) why it is five or six times as common in win as in single pregnancy, (5) why it occurs in 50% of chronic hypertensive pregnancies, (6) its greater frequency n diabetic pregnancy, (7) why it is often associated with "red infarcts" in the placenta, or with concealed accidental hæmorrhage, and sometimes with renal cortical necrosis, and (8) why it often occurs two or three days after delivery (10% of all cases) This last has been the chief obstacle to the acceptance of all published theories, ncluding those of Young (1914), Paramore (1929), Beker (1948), Van Bouwdijk Bastiaanse and Mastboom (1950), Parviainen et al (1950a and b), Louros and Kairis (1951), Sophian (1953), Theobald (1955), and Bartholomew et al (1957)

Hormones in Normal Pregnancy

In normal pregnancy the anterior lobe of the pituitary gland hypertrophies and produces excess of corticotrophin This is no doubt due to œstrogens secreted by the placenta, which, besides the fœtus, is the only new organ in the pregnant woman

Corticotrophin is also produced by the placenta (Cohen and Kleinberg 1952, Assali, Hamermesz, and Ross 1954) Under this double stimulus the adrenal cortex undergoes hyperplasia and secretes excessive amounts of cortical metabolites, including glucocorticoids (11-oxycorticosteroids), which have an anti-insulin effect on carbohydrate metabolism and are the basis of the well-known delayed sugar-tolerance curve characteristic of normal pregnancy Under the influence of corticotrophin the adrenal cortex also secretes excess of the mineralocorticoids (11-deoxycorticosteroids), which retain sodium, chloride, and water Aldosterone, though probably largely responsible for the œdema both of normal pregnancy and of toxæmia, does not seem to be under the influence of the anterior lobe of the pituitary gland or of corticotrophin but to be regulated by sodium and water balance

At this point let me cite some rather striking evidence of the powerful sodium-retaining and pressor effects of adrenocortical compounds

Ferrebee et al (1939) treated 13 cases of Addison's disease with deoxycortone acetate or propionate This caused a striking retention of salt and water, the urine diminishing to 410 ml in twenty-four hours in one patient receiving a daily dose of 15 mg The blood-pressure rose from subnormal to normal levels in two to four weeks, and in 3 of the cases it rose gradually to 160/92, 160/110 and 146/108 mm Hg Of the 13 patients 10 developed œdema, varying from mild puffiness of the face and ankles to massive anasarca

Altschule and Zamcheck (1942) reported the case of a man, aged 43, who had asthma for many years but no evidence of adrenal cortical insufficiency Because of eczema, which he had had for years, sodium chloride 5 g by mouth daily and extract of suprarenal cortex 1 ml daily intramuscularly had been prescribed At that time his blood-pressure was 120/80 mm Hg and serum-protein level 5 9 g per 100 ml He received altogether 7 ml of extract of suprarenal cortex in the daily doses Severe œdema developed in his legs and soon involved his whole body, and in consequence he was admitted to hospital He then had rapid respiration, dyspnœa, orthopnœa, œdema of face, arms, legs, and trunk, and effusion into his body cavities His urine contained much albumin, casts, and a few red blood-cells His blood-pressure was 200/110 mm Hg and serum-protein level 4 42 g per 100 ml There was no evidence of congestive heart-failure Altschule and Zamcheck considered that "the syndrome closely resembles that produced by a diffusely active vascular toxin" The lowered serum-protein level suggests injury to the capillary walls by the "vascular toxin"

In this connection it is of interest to recall that examination of the œdema fluid in 3 cases of gross œdema in severe pre-eclamptic toxæmia in the obstetric department of University College Hospital, London, showed protein levels of 0 5, 0 57, and 0 9 g per 100 ml Since the normal protein level in interstitial fluid is exceedingly low (less than 0 1 g per 100 ml), this increase clearly indicates injury to the capillaries, an additional cause of the often rapidly forming œdema of pre-eclamptic toxæmia Incidentally this demonstration of injury to the capillaries by a vascular toxin justifies the retention of the term "toxæmia of pregnancy"

Though the deoxycortone acetate used by Ferrebee et al (1939) was a synthetic compound and is probably not produced to any great extent by the adrenal glands, its action in causing œdema and hypertension is of great interest It is probable that the chief cause of œdema in pre-eclamptic toxæmia is an increased secretion of salt- and water-retaining hormone by the adrenal cortex, but a contributory factor may be antidiuretic hormone, which Hawker (1952, 1957) has shown to be increased in the plasma of patients with pre-eclamptic toxæmia compared with normal pregnancy Hawker has found too that, in normal pregnancy, this hormone is kept in check by a placental enzyme which does not do so in pre-eclamptic toxæmia

We shall presently see that hydrocortisone (compound F) can cause in laboratory animals as great a rise of blood-pressure as can deoxycortone acetate In passing it is important to note that deoxycortone acetate does not raise the blood-pressure in healthy pregnant women In 1946, during my own investigations of the cause of the hypersensitivity of the vascular system in toxæmia, I was surprised to find that injected extract of suprarenal cortex in the same doses as used by Altschule and Zamcheck (1942) had no effect whatever in raising the blood-pressure in healthy pregnant women The probable reason for this has now come to light

---

* Paper read at a joint meeting of the Colloquia on Hypertension and Pregnancy Toxæmia and the 4th Conference in Australia of the Royal College of Obstetricians and Gynæcologists, Sydney, Aug 28, 1957

Hypertensive effects of Corticotrophin, Cortisone, and Hydrocortisone

Hydrocortisone and cortisone raise the blood-pressure, both systolic and diastolic, in rats at least as much as and probably more than does deoxycortone acetate after two weeks' treatment in intact (non-adrenalectomised) rats (Friedman et al 1952, Knowlton et al 1952) It is now well known that hypertension occasionally develops during therapy with corticotrophin and with cortisone (Zweifach and Shorr 1950, Cope and Hurlock 1954) Perera (1950) observed the effect of corticotrophin on the resting blood-pressure of 13 non-pregnant patients, a rise occurred in the great majority In one patient with hypertension the administration of corticotrophin 100 mg daily for nine days was followed by a rise of blood-pressure, hypertensive encephalopathy, and mental confusion

Increase of Corticosteroids in Normal and in Toxæmic Pregnancy

Bayliss et al (1955) followed the plasma levels of 17-hydroxycorticosteroids at monthly intervals through the normal pregnancies of 30 women The level rose progressively during normal pregnancy, becoming in some cases very high, after delivery the level fell and was normal again after a week Gemzell (1953) found that the concentration of 17-hydroxycorticosteroids (which include hydrocortisone) in the blood in the last three months of normal pregnancy was four times the pre-pregnancy value Immediately after delivery it increased to seven times the normal value, but by the sixth day it had fallen to pre-pregnancy level The significance of this rise immediately after delivery will be discussed later

Many investigators have found that, in toxæmia, the urinary excretion of corticosteroids is considerably larger than in normal pregnancy (Tobian 1949, Parviainen 1950a and b, Chart et al 1951, Lloyd et al 1952, Venning et al 1954)

I am aware that Assali et al (1955) found that the blood levels of 17-hydroxycorticosterones were not raised in toxæmia compared with normal pregnancy The glucocorticoids alone, however, were estimated, not the mineralocorticoids, which are probably the hormones chiefly involved in pregnancy toxæmia Assali et al (1955), commenting on their results, state

> " By excluding glucocorticoids from involvement in toxæmia our results lend support to the work of the aforementioned investigators (i e , Venning, Tobian, Lloyd et al) which indicates that mineralocorticoids may be the hormones involved in this abnormality "

It should be here noted that Chart et al (1951) found much increased excretion of a sodium-retaining factor in toxæmic pregnancy but no parallel increase in the excretion of 11-oxysteroids (glucocorticoids)

Cushing's Syndrome and Normal Pregnancy

There are several resemblances between normal pregnancy and Cushing's disease, which is now regarded as due, in most cases, to hyperplasia of the adrenal corte J S L Browne, indeed, has spoken of normal pregnan as "a kind of physiological Cushing's syndrome Examples of this resemblance are insensitivity to insul adiposity, osteoporosis, striæ, sodium retention, a hypertension, which is present in Cushing's syndro in 90% of cases Study of 15 cases of normal pregnan by Bush and Pickering (Bush 1953) has shown that t blood-level of 17-hydroxycorticosterone is within t range of that found in Cushing's disease

> " Thus the increased rate of adrenocortical secretion pregnancy, indicated by clinical findings and estimations urinary steroids, is also associated with an increased conce tration of adrenocortical hormone in the peripheral veno blood " (Bush 1953)

I have discussed Cushing's syndrome at some leng because it shows that blood-pressure-raising hormon are produced by the adrenal cortex in normal pregnanc I shall suggest later that hypertension similar to that Cushing's disease would develop in every pregnant wom if it were not for the protective placenta Striæ oft appear in pregnancy on the upper and outer aspects the thighs, where they could not be due to stretching the skin or to deposit of fat over the fascia lata They a very well-known side-effects of cortisone, and thoug they are usually present in Cushing's disease, even thin legs, they may be absent, as they often are, pregnant women

The Protective Placenta

It will be evident that the normal overaction of th anterior lobe of the pituitary gland and of the adren cortex can cause the syndrome of pre-eclamptic toxæmi including œdema, hypertension, and albuminuria Wh then does not every pregnant woman become hype tensive? That she becomes œdematous is well know and that half the weight gain of normal pregnancy due to retention of water—i e , 12 lb or 6 litres of water

In 1948 it was shown that there is present in the norm human placenta and decidua a highly active mono-amin oxidase that can inactivate vasoconstrictor amines—e g adrenaline and tyramine Its activity increases as the placen matures, and is diminished or inhibited by a decrease in t oxygen tension of the medium in which it acts (Luschinsky a Singher 1948, Thompson and Tickner 1949) The significan of this work could not be appreciated in 1948, because work had been done on the maternal placental blood-flo Browne and Veale (1953), however, by injecting radioacti sodium into the placental blood sinuses and measuring its ra of disappearance in healthy, pre-eclamptic, and chronical hypertensive women, showed that there was a reduction about half in the pre-eclamptic and chronically hypertensi women compared with the healthy women This reductio could decrease the oxygen tension within the placenta, and th finding of a decreased oxygen tension in the cord blood toxæmia (Walker 1954) suggests that this actually happens

It will be clear, therefore, that in normal pregnanc when the placenta has not been made ischæmic, press substances can be wholly or partly destroyed, in placent ischæmia, however caused, the enzyme cannot exert i anti-pressor activity, with consequent failure of degrad tion of vasoconstrictor substances produced by th adrenal glands

Corroborative evidence of this activity is found in th fact that, though corticotrophin causes hypertension non-pregnant women, it does not do so in health pregnant women Assali and Suyemoto (1954) ga intramuscular corticotrophin 120 mg for four, five, an

Sensitisation of Vascular System

That the vascular system is hypersensitive in pre-eclamptic toxæmia was first demonstrated by Schockhaert and Lambillon (1937) and Dieckmann and Michel (1937), and confirmed by De Valera and Kellar (1938) and myself (Browne 1943)

That this hypersensitivity is not hereditary or constitutional but acquired between about the seventeenth week and the time at which toxæmia becomes clinically manifest was shown by me in 1946 (Browne 1946), when I found evidence that its cause was chorionic gonadotrophin. This finding that the sensitisation is acquired in the course of pregnancy rules out the suggestion that pre-eclamptic toxæmia develops only in women with a familial predisposition to chronic hypertension I was unable to pick out, by the cold pressor test, women who would develop toxæmia in later pregnancy (Browne 1940)

Byrom (1937) produced, in rats, lesions closely resembling those of eclampsia—focal necrosis of the liver and symmetrical cortical necrosis in the kidneys—by injecting vasopressin. He believed the lesion to be due to arteriolar spasm. He also found that the sensitivity to vasopressin could be increased ten times by œstrogenic hormones, and that, in unspayed rats, the sensitisation could equally well be brought about by gonadotrophic hormones

All the evidence therefore goes to show that sensitisation of the vascular system, acquired from whatever cause in pregnancy, plays a part in the ætiology of toxæmia

I am aware that the adrenocorticosteroids are not mono-amines They are all combinations of carbon, hydrogen, and oxygen, and I suggest that the normal placenta contains an oxygen-sensitive oxidase that can inactivate them This is a matter for further investigation

What is the purpose of this elaborate mechanism that has been developed during the course of normal pregnancy in the internal secretory organs, including the placenta? I suggest that it is designed to protect the fœtus from the dangerous consequences of low blood-pressure that would otherwise occur, and increase as pregnancy advances, through pooling of blood in the maternal placental blood lake combined with the erect posture (Theobald 1955) The result is that, in the great majority of cases, the blood-pressure is nicely adjusted to that end and kept at normal levels, neither hypotensive nor hypertensive, by the protective placenta Through various causes this healthy adjustment sometimes fails, and pre-eclamptic toxæmia and eclampsia are the consequences There is no need to think of them as "diseases of adaptation", because the stimulus for the adrenal cortex is in the placenta

Summary

Under the influence of corticotrophin produced by the placenta and the anterior lobe of the pituitary gland (the latter stimulated by œstrogens secreted by the placenta) the adrenal cortex in pregnancy produces excess of cortical metabolites, including glucocorticoids and mineralocorticoids

There are several resemblances between normal pregnancy and Cushing's syndrome, which is usually due to hyperplasia of the adrenal cortex and is in 90% of cases accompanied by hypertension In normal pregnancy there must therefore be a pressor substance produced in excess (compared with the non-pregnant individual) by the adrenal cortex The blood in normal pregnancy contains 17-hydroxycorticosteroids equal in amount to or exceeding those in Cushing's syndrome.

Every pregnant woman would become hypertensive if it were not for the protective placenta which furnishes, it is suggested, an oxygen-sensitive oxidase that inactivates pressor hormones from the adrenal cortex The presence of this enzyme would explain the fact that cortical hormones, which in the non-pregnant individual cause hypertension and œdema, are without effect in healthy pregnant women If from any cause the placenta is made ischæmic and its oxygen tension lowered, the protective enzyme is made ineffective, and hypertension results

The excess of chorionic gonadotrophin present in pre-eclamptic toxæmia can be explained by its non-destruction There is evidence that it causes the hypersensitivity of the vascular system known to exist in pre-eclamptic toxæmia.

In 25–30% of women who have been normotensive during pregnancy and labour the blood-pressure reaches hypertensive levels in the first three days after delivery This can be correlated with Gemzell's (1953) findings that the level of 17-hydroxycorticosteroids in the blood before labour is increased by nearly 100% immediately after the birth of the placenta Dangerous eclamptogenic rises of blood-pressure often occur in toxæmic patients after delivery It is suggested that the birth of the placenta and the loss of its inactivating effect on pressor hormones explain the onset of eclampsia in the first three days of the puerperium in women who have had pre-eclamptic toxæmia before delivery

references continued at foot of next col

eclampsia within the first three days of the puerperium Fits occurring after that time are, I suggest, due to one of two causes primary cerebral venous thrombosis (Martin and Sheehan 1941) and subarachnoid hæmorrhage In all such cases a neurologist should be called in and, when subarachnoid hæmorrhage is a possibility, lumbar puncture should be done to exclude blood in the cerebrospinal fluid

If this explanation of the absence of hypertension in normal pregnancy and of the occurrence of eclampsia in the first three days after delivery is correct, we would expect a rise of blood-pressure after the birth of the placenta in women whose blood-pressure has been normal throughout pregnancy and labour I have not been able to find any reference to this in textbooks, and it seems to have been assumed that the blood-pressure is always normal Examination of blood-pressures of such women at the Royal Hospital for Women, Sydney, and at the Postgraduate Medical School of London, has, however, shown that 20–30% are hypertensive in the first three days after delivery This is remarkable when it is considered that these women are at rest, are tired after labour, and have often lost a considerable amount of blood Intramuscular ergometrine 0 5 mg was given routinely at the end of the second stage, but the puerperal blood-pressures were not taken until between twelve and twenty hours after delivery, and some much later It is therefore unlikely that any of the hypertensions were due to ergometrine

Rise of Blood-pressure in Toxæmic Patients after Delivery

During the last week several examples of this have come to my notice without seeking or searching

(1) *Mrs A,* aged 27, first pregnancy, multiple pregnancy, and pre-eclamptic toxæmia *May 1, 1957* membranes stripped and medical induction given *May 3* artificial rupture of membranes and oxytocin drip *May 4* episiotomy and breech extraction of first infant, forceps delivery of second, manual removal of placenta because of postpartum hæmorrhage, intramuscular ergometrine 0 5 mg given, after delivery blood-pressure rose remarkably to 170/120 mm Hg From this time onward the patient progressively deteriorated and died at 1 45 A M on *May 5* Necropsy revealed a liver with findings typical of eclampsia

(2) Bulfin and Lawler (1957) review 234 sets of twins delivered beyond seven months' gestation, and state that there were 12 cases "in which the excessive rise in blood pressure post-partum resulted in headache, nausea and visual disturbances, creating all the appearances of impending eclampsia In retrospect we now feel that the injudicious use of ergonovine in these patients already toxæmic could have been responsible for the fulminating post-partum symptoms" They state that intravenous ergometrine maleate occasionally causes acute hypertension which persists from half an hour to four hours "The hypertensive effect of this drug seems to be even more pronounced in the patient whose uterus is contracting following distension from a twin pregnancy"

(3) Dugan and Black (1957), discussing kyphoscoliosis in pregnancy, review 39 pregnancies in twenty-two hospitals and give a detailed account of 1 fatal case This woman had toxæmia and was delivered vaginally by forceps after pudendal block The placenta and membranes were complete, and there was no postpartum bleeding At 2 30 P M, forty-five minutes after delivery, the patient's pulse-rate was 122 and blood-pressure 148/80 mm Hg At 3 30 P M, one and three-quarter hours after delivery, her blood-pressure was 180/100 mm Hg She had a generalised convulsion, which lasted about three minutes Her condition steadily deteriorated, and she died at 7 P M During labour she had been given pethidine and scopolamine and, because of severe restlessness during delivery, intravenous morphine sulphate gr $^1/_6$ There is no note about whether ergot was given or not

Eclamptic Fits

These are caused by a rapidly rising systolic bloo pressure causing hypertensive encephalopathy, and cerebral œdema

That a rapidly rising systolic blood-pressure alone can cau convulsions is shown by Byrom's (1954) experiments on ra He removed one kidney and clamped the renal artery of t other In the weeks after the operation the systolic bloo pressure rose and ultimately, when it reached an excessiv high level (over 200 mm Hg), especially if it rose steeply, fa convulsions came on Through a 'Perspex' window in th rat's skull spasm was seen in the cerebral arterioles during th convulsions

Œdema of the brain alone can cause fits Rowntree (192 showed that by giving 50 ml of water per kg of body-weig to dogs every half-hour—i e, faster than the kidneys cou excrete it—he could produce convulsions, coma, and dea in a few hours Necropsy revealed œdema of the connectiv tissues, liver, kidneys, and brain Rowntree demonstrat increased intracranial pressure during life and believed this t be the cause of the convulsions

It is possible that hypertension and œdema can suppleme each other as eclamptogenic agents, that fits can occur if systol blood-pressure rises quickly to a high level with little or n œdema, as in Byrom's (1954) rats, and that they may occur i there is cerebral œdema alone if the blood-pressure is normal o near normal, as in Rowntree's (1923) dogs

Cerebral dysrhythmia may possibly predispose to fits, but the evidence is inconclusive (Rosenbaum and Maltby 1943, Parviainen et al 1950a and b, Macintosh 1952, James 1955, Poidevin 1955) Recently I saw a patient who had pre-eclamptic toxæmia and idiopathic epilepsy, but eclampsia did not develop

This view of the cause of eclamptic fits received support from the results in Cincinnati, U S A, where treatment of eclampsia is based on the assumption that the fits are due to cerebral vascular spasm, and that if it is relieved they will cease This is achieved by giving alkaloids of veratrum viride, œdema is also treated with intravenous dextrose, and magnesium sulphate, 50% solution, is injected intramuscularly as a sedative and anticonvulsant to relax the cerebral vasospasm (McCall and Sass 1956) No other sedatives are given To date 205 consecutive cases have been reported with only 3 deaths, 2 of which took place in pre-antibiotic days from puerperal sepsis, one fourteen days and the other sixty-five days after cure of the eclampsia and delivery This is an uncorrected maternal mortality of 1 5% (Bryant and Fleming 1940, Garber 1953)

Role of Diet in Causing Toxæmia

The greatly increased frequency of eclampsia in patients with beriberi (King and Ride 1945) and in areas of the United States where pellagra is endemic suggests that vitamin-B complex may be essential for the action of the placental enzymes Hipsley (1953) has found that eclampsia is much less common among races that consume large amounts of fibre in their diet I think that the fibre may contain vitamin B Possibly other dietary factors—e g, calcium and vitamin D—are also important in this connection (Theobald 1955) Perhaps a high-carbohydrate diet, by raising the blood-sugar level, calls for a greater output of insulin and therefore of growth hormone to provide it, and as a consequence of this an increased output of corticotrophin This might explain the value of a low-carbohydrate diet in preventing toxæmia (Stevenson 1952, Hamlin 1952, J Woodhill, personal communication, and others)

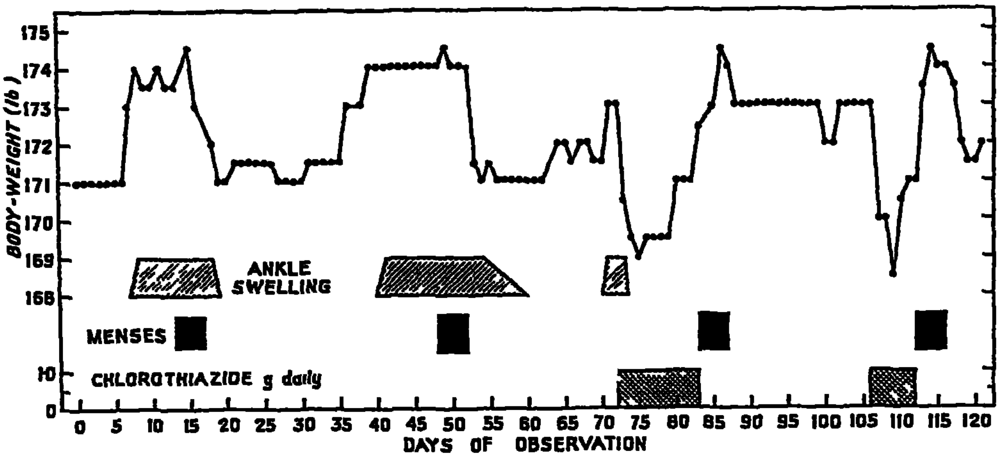

Fig 4—Patient no 18 with premenstrual œdema.

Chlorothiazide given before the third and fourth menstrual periods largely controls the symptoms and weight gain, but should have been continued during the menstruation

sodium, chloride, or bicarbonate levels were observed, but the serum-potassium level tended to fall (as shown in fig 2), and in all eleven patients whose urinary excretion of electrolytes was studied there was increased loss of potassium In three patients the serum-potassium level dropped to below 3 mEq per litre without symptoms of potassium depletion, and a fourth had such symptoms with a serum-potassium level of 3 1 mEq Chlorothiazide was given daily to three of these patients, and for 4 days each week to the fourth In two the daily intake of sodium was 22 mEq, in one it was 87 mEq, and in the fourth, with nephrosis and heavy proteinuria, it was 218 mEq

No changes in liver-function tests, white-cell and platelet counts, or hæmoglobin levels were seen None of the patients developed gastro-intestinal or other symptoms attributable to chlorothiazide, with the single possible exception of the cirrhotic patient (no 21), who became anorexic and felt unwell

Comparison with Mersalyl

A detailed comparison of the potency of chlorothiazide and mersalyl will be reported elsewhere It will be seen, however, from table I and from fig 2 that patients who responded poorly or not at all to bi-weekly injections of mersalyl may have a satisfactory diuresis on chlorothiazide

Refractoriness to mersalyl, despite persisting œdema, may be due to the severity of the patient's condition, a low glomerular filtration-rate, or electrolyte imbalance (Stock et al 1951) None of these eleven patients who responded poorly to mersalyl had hypochloræmic alkalosis, hyponatræmia, or hypokalæmia, yet five of them gave a good and four a fair response to chlorothiazide Fig 3, for example, shows little fall in weight on days 20 and 22, when mersalyl alone was given, but a good diuresis and weight loss when continuous chlorothiazide treatment was started on day 24

Chlorothiazide and mersalyl given together produce a greater diuresis than either given alone For example, in fig 3 electrolyte and water excretion was greater on day 12, when the two agents were given together, than on days 6, 10, and 14, when chlorothiazide was given alone, or on days 16, 20, and 22, when mersalyl was given alone Furthermore, chlorothiazide may increase the response to mersalyl in patients who have become mersalyl-resistant, if the two agents are given together (Bayliss et al 1958) This enhanced response to combined treatment may be of clinical value in patients whose œdema fails to clear completely on chlorothiazide alone, and suggests that chlorothiazide and mersalyl may influence two different mechanisms for the tubular reabsorption of chloride

Discussion

The ideal diuretic should (*a*) be effective by mouth, (*b*) be at least as potent as mersalyl, (*c*) cause a proportionate loss of sodium, chloride, and water, (*d*) not induce any electrolyte imbalance, (*e*) not lose its effectiveness (so that it can be given continuously if necessary and allow the seriously incapacitated patient to eat a diet containing a palatable amount of sodium chloride), and (*f*) be devoid of toxic effects Such a substance does not exist, but chlorothiazide meets many of these desiderata It is effective by mouth, causes almost equimolar loss of sodium and chloride, and in our experience has been outstandingly free from toxic effects It may cause potassium depletion, and is not always therapeutically effective, but it would be difficult to imagine any substance that would unfailingly induce a diuresis in severe congestive cardiac failure, particularly when the glomerular filtration-rate is much reduced Many of the cardiac patients who showed a poor or fair response to chlorothiazide were old, chronically ill, and resistant to other forms of treatment Indeed it is more remarkable that several of this type (e g, nos 1, 5, 7, 8, and 16) responded to chlorothiazide at all

Potassium depletion and hypokalæmia may develop during treatment with any diuretic that increases the excretion of chloride or bicarbonate, and the more potent the diuretic the more likely is this to happen Usually the increased amount of chloride excreted will be accompanied by sodium, but, if the amount of available sodium is reduced—either because of rigid dietary restriction, or because of intense tubular reabsorption of sodium—potassium may be excreted instead Our experience shows that continuous daily administration of 2 g chlorothiazide may cause potassium depletion, and as daily treatment may be necessary for a long time in severely ill refractory patients, a careful watch should be kept on the serum-potassium level, and daily supplements of potassium chloride 2–6 g in capsules should be given to prevent hypokalæmia In less severe cases which respond quickly, continuous administration of chlorothiazide 2 g daily is necessary for only a few days, and thereafter a smaller dose, 1 0–1 5 g daily, can be used and maintenance therapy given intermittently on 3–4 days each week

Summary

The value of chlorothiazide, a non-mercurial orally effective diuretic, has been assessed in 24 œdematous

TABLE II—SUMMARY OF RESULTS

Disease	Response*		
	Good	Fair	Poor
Congestive heart-failure			
Ischæmic heart-disease	4	1	1
Hypertensive heart-disease	5	3	0
Valvular heart-disease	1	1	1
Hepatic cirrhosis	0	0	1
Nephrosis	0	1	0
Premenstrual œdema	3	0	0
Miscellaneous	1	1	0
Total	14	7	3

*See text.

with a weight loss of 15 lb in 9 days The serum-potassium level fell, and, when the sodium intake was increased from 87 to 218 mEq per day, the œdema recurred with a weight gain of 4 lb

Another hypertensive patient (no 13), with renal insufficiency, lost 12 lb spontaneously during the first 10 days in hospital When he was almost œdema-free, chlorothiazide increased the natriuresis and induced a further loss of 6 lb in the next 10 days, but the blood-urea rose from 50 mg per 100 ml on admission to 150 mg No abnormality of the electrolytes was found, and as there was no dehydration (judged by the extracellular-fluid volume, which had fallen from 23 0 litres to a normal value of 15 4 litres), the azotæmia was attributed to a further deterioration in renal function

The third patient (no 14), who showed only a fair response, became œdema-free on chlorothiazide, but increased activity led to some reaccumulation of fluid

Valvular heart-disease—There were three patients in this group

One (no 15) responded well, losing 10 lb in weight and becoming œdema-free

A second (no 16), who had been in chronic congestive failure for 3 years with frequent hospital admissions, was readmitted with gross œdema Bi-weekly injections of mersalyl for 17 days produced no improvement, and he gained 3 lb Chlorothiazide (2 g daily for a week and then 3 g daily for 10 days) caused only a 5 lb loss of weight The addition of mersalyl induced a further diuresis, and the weight fell another 10 lb This result, which can only in part be attributed to chlorothiazide (although seemingly as a result of its use the patient became responsive to mersalyl), has been classified as fair The third patient (no 17) had been in failure for many months with mitral stenosis, aortic incompetence, tricuspid incompetence, and cardiac cirrhosis No significant improvement followed treatment with chlorothiazide or mersalyl (with or without ammonium chloride) either singly or in combination

Premenstrual œdema

All three patients responded well to chlorothiazide given 7–10 days before the onset of their menses, when symptoms were liable to start The result in 1 of these patients is shown in fig 4

Cirrhosis

One patient with alcoholic cirrhosis, ascites, and œdema of the legs lost 7 lb in 8 days Treatment was stopped because she felt increasingly anorexic and unwell, but as no electrolyte abnormality was found, her symptoms were probaby more related to sudden withdrawal of alcohol than to chlorothiazide

Nephrosis

This patient with chronic spinal tuberculosis had amyloid nephrosis, shown by finger-clubbing, hypoalbuminæmia, heavy proteinuria, and 75% retention of congo-red

Chlorothiazide induced a striking diuresis and weight loss of 26 lb, the extracellular-fluid volume falling from 29 9 to 18 5 litres Despite continuing hypoproteinæmia the patient was œdema-free, and the dose of chlorothiazide was reduced from 2 to 1 g daily Although he was on a high-protein diet containing 218 mEq of sodium, hypokalæmia of 2 8 mEq per litre developed, and a potassium supplement of 80 mEq daily was given to correct this The œdema returned and was not controlled until the dose of chlorothiazide was raised to 4 g daily Chlorothiazide did not increase the urinary concentration of protein, 40 g daily being excreted during the diuretic phase

Miscellaneous

One patient (no 23) with œdema of the legs and abdominal wall due to malignant obstruction of the inferior vena cava showed a good response and lost 13 lb in 14 days Another with cirrhosis (no 24), who developed œdema after a portacaval anastomosis, was only fairly well controlled on chlorothiazide 1 g given for 4 days each week, and became hypokalæmic

Electrolyte Disturbances and Toxic Effects

On the intake of sodium chloride given to these patients no significant changes in serum

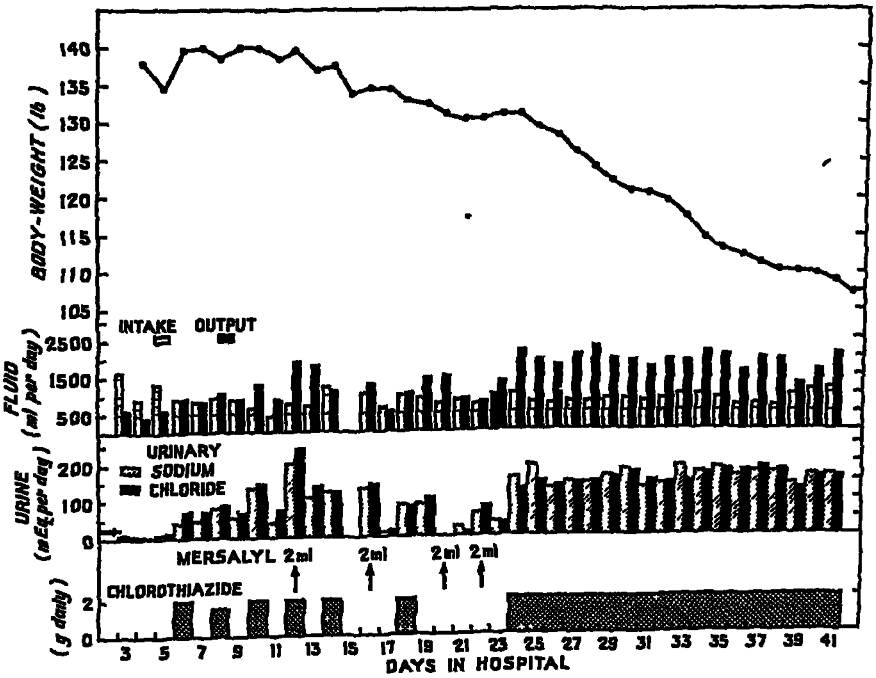

Fig 3—Patient no 7, aged 71, with hypertensive heart-disease

The dietary sodium intake (22 mEq daily) is shown by the arrow on the sodium and chloride scale Note gradual increase in sodium and chloride excretion on days 6, 8, and 10 when chlorothiazide is given on alternate days On day 12 the combination of mersalyl and chlorothiazide causes a further increase in the water and sodium diuresis On day 22 there is a poor response to mersalyl alone and no weight loss A good response follows 2 g chlorothiazide daily started on day 24

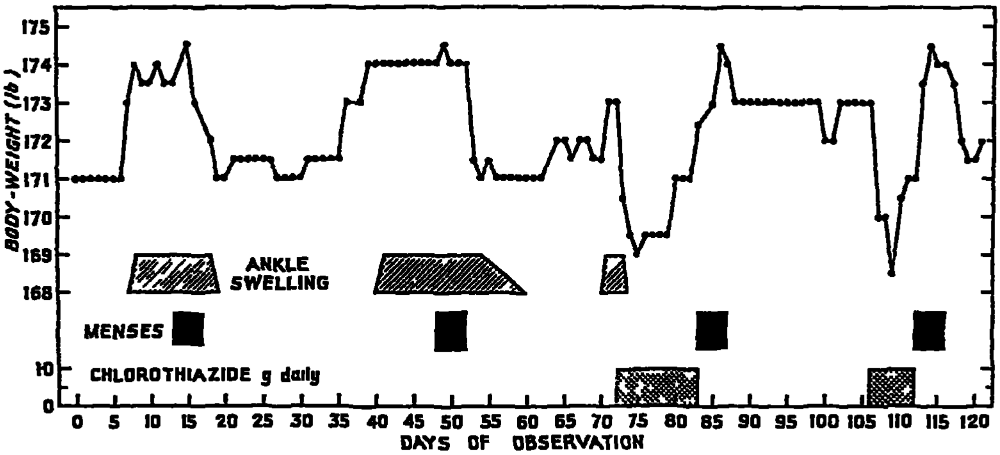

Fig 4—Patient no 18 with premenstrual œdema.

Chlorothiazide given before the third and fourth menstrual periods largely controls the symptoms and weight gain, but should have been continued during the menstruation

sodium, chloride, or bicarbonate levels were observed, but the serum-potassium level tended to fall (as shown in fig 2), and in all eleven patients whose urinary excretion of electrolytes was studied there was increased loss of potassium In three patients the serum-potassium level dropped to below 3 mEq per litre without symptoms of potassium depletion, and a fourth had such symptoms with a serum-potassium level of 3 1 mEq Chlorothiazide was given daily to three of these patients, and for 4 days each week to the fourth In two the daily intake of sodium was 22 mEq, in one it was 87 mEq, and in the fourth, with nephrosis and heavy proteinuria, it was 218 mEq

No changes in liver-function tests, white-cell and platelet counts, or hæmoglobin levels were seen None of the patients developed gastro-intestinal or other symptoms attributable to chlorothiazide, with the single possible exception of the cirrhotic patient (no 21), who became anorexic and felt unwell

Comparison with Mersalyl

A detailed comparison of the potency of chlorothiazide and mersalyl will be reported elsewhere It will be seen, however, from table I and from fig 2 that patients who responded poorly or not at all to bi-weekly injections of mersalyl may have a satisfactory diuresis on chlorothiazide

Refractoriness to mersalyl, despite persisting œdema, may be due to the severity of the patient's condition, a low glomerular filtration-rate, or electrolyte imbalance (Stock et al 1951) None of these eleven patients who responded poorly to mersalyl had hypochloræmic alkalosis, hyponatræmia, or hypokalæmia, yet five of them gave a good and four a fair response to chlorothiazide Fig 3, for example, shows little fall in weight on days 20 and 22, when mersalyl alone was given, but a good diuresis and weight loss when continuous chlorothiazide treatment was started on day 24

Chlorothiazide and mersalyl given together produce a greater diuresis than either given alone For example, in fig 3 electrolyte and water excretion was greater on day 12, when the two agents were given together, than on days 6, 10, and 14, when chlorothiazide was given alone, or on days 16, 20, and 22, when mersalyl was given alone Furthermore, chlorothiazide may increase the response to mersalyl in patients who have become mersalyl-resistant, if the two agents are given together (Bayliss et al 1958) This enhanced response to combined treatment may be of clinical value in patients whose œdema fails to clear completely on chlorothiazide alone, and suggests that chlorothiazide and mersalyl may influence two different mechanisms for the tubular reabsorption of chloride

Discussion

The ideal diuretic should (*a*) be effective by mouth, (*b*) be at least as potent as mersalyl, (*c*) cause a proportionate loss of sodium, chloride, and water, (*d*) not induce any electrolyte imbalance, (*e*) not lose its effectiveness (so that it can be given continuously if necessary and allow the seriously incapacitated patient to eat a diet containing a palatable amount of sodium chloride), and (*f*) be devoid of toxic effects Such a substance does not exist, but chlorothiazide meets many of these desiderata It is effective by mouth, causes almost equimolar loss of sodium and chloride, and in our experience has been outstandingly free from toxic effects It may cause potassium depletion, and is not always therapeutically effective, but it would be difficult to imagine any substance that would unfailingly induce a diuresis in severe congestive cardiac failure, particularly when the glomerular filtration-rate is much reduced Many of the cardiac patients who showed a poor or fair response to chlorothiazide were old, chronically ill, and resistant to other forms of treatment. Indeed it is more remarkable that several of this type (e g, nos 1, 5, 7, 8, and 16) responded to chlorothiazide at all

Potassium depletion and hypokalæmia may develop during treatment with any diuretic that increases the excretion of chloride or bicarbonate, and the more potent the diuretic the more likely is this to happen Usually the increased amount of chloride excreted will be accompanied by sodium, but, if the amount of available sodium is reduced—either because of rigid dietary restriction, or because of intense tubular reabsorption of sodium—potassium may be excreted instead Our experience shows that continuous daily administration of 2 g chlorothiazide may cause potassium depletion, and as daily treatment may be necessary for a long time in severely ill refractory patients, a careful watch should be kept on the serum-potassium level, and daily supplements of potassium chloride 2–6 g in capsules should be given to prevent hypokalæmia In less severe cases which respond quickly, continuous administration of chlorothiazide 2 g daily is necessary for only a few days, and thereafter a smaller dose, 1 0–1 5 g daily, can be used and maintenance therapy given intermittently on 3–4 days each week.

Summary

The value of chlorothiazide, a non-mercurial orally effective diuretic, has been assessed in 24 œdematous

patients, of whom 17 had congestive heart-failure and 11 had responded poorly to mersalyl

A daily dose of 2 g produced good results (with clearing of the œdema) in 14 patients In 7 the results were less satisfactory, and in 3 they were poor

Chlorothiazide may be effective in patients who do not respond to mersalyl, and it enhances the response to mersalyl even in patients who have become mersalyl-resistant

Except for 1 patient who developed malaise and anorexia, no toxic effects were observed

Chlorothiazide may cause potassium depletion, particularly if continuous treatment with 2 g daily is given over a long period In refractory cases this dosage may be required and should be supplemented with 2–6 g potassium chloride (sufficient to maintain a normal serum-potassium level) In less severe cases which respond quickly a smaller dose of chlorothiazide (1 0–1 5 g daily) may suffice, and for maintenance therapy the drug may be given intermittently on three or four days each week

We are grateful to Drs C J Gavey and F Dudley Hart for allowing us to study patients under their care, to Miss Margaret Wood and Miss Jill Nuttall for technical assistance, and to Messrs Merck Sharp & Dohme for generous supplies of chlorothiazide ('Saluric')

ASSISTANT PHYSICIAN

THE MIDDLESEX HOSPITAL, LONDON, W 1

From the Institute of Clinical Research of the Middlesex Hospital Medical School

CHLOROTHIAZIDE is a new oral non-mercurial diuretic Chemically it is 6-chloro-7-sulphamyl-1,2,4-benzothiadiazine-1, 1-dioxide, a heterocyclic compound containing a sulphonamido group Preliminary studies by Ford et al (1957) have shown that it is as effective as the mercurial diuretics In vitro it inhibits carbonic anhydrase but in vivo it causes a considerable increase in the rate of excretion of chloride and sodium without producing metabolic acidosis The effect on chloride output is unlike the action of carbonic anhydrase inhibitors (Hanley and Platts 1956) and resembles the action of organic mercurial compounds

We report here our initial clinical experience with chlorothiazide in three patients with the nephrotic syndrome, one patient with ascites due to portal hypertension, and one patient with congestive heart-failure A short-term study designed to assess its effect on renal carbonic anhydrase is also described

Case-reports

Case 1—A woman, aged 38, developed the nephrotic syndrome in September, 1956 Her serum-albumin level was 1 8 g per 100 ml, urinary output of protein 25 g daily, and serum-cholesterol level 1300 mg per 100 ml However, in addition, she had hypertension (B P 190/100 mm Hg), granular casts, white and red blood-cells in her urine, and retention of urea (blood-urea level 34–62 mg per 100 ml) She has been maintained on a low-sodium diet (initially 44 mEq and later 22 mEq daily) Prolonged treatment with cation exchange resins and later with prednisone did not produce any permanent improvement

Treatment with chlorothiazide 500 mg six-hourly, started in May, 1957, caused a rapid well-marked diuresis with increased excretion of sodium and chloride Her body-weight fell by 3 9 kg in six days She then had a transient attack of abdominal pain, diarrhœa, and vomiting Chlorothiazide was withheld, and she lost 3 0 kg Renewed administration of chlorothiazide (500 mg twelve-hourly) ten days later did not cause gastro-intestinal symptoms, and she has now taken chlorothiazide intermittently—one week every alternate week—for six months without ill effect Her weight has remained steady, and she feels well and is almost free from œdema Persistent hypokalæmia has developed and is only partially controlled by an extra 40–80 mEq of potassium daily (potassium chloride 3–6 g) No clinical effects attributable to hypokalæmia can be recognised

Case 2—A woman, aged 49, developed the nephrotic syndrome in March, 1956 Her serum-albumin level was 1 7 g per 100 ml, urinary output of protein 22 g daily, and serum-cholesterol level 780 mg per 100 ml Her blood-pressure was normal Her urine contained white blood-cells and a few red blood-cells but no casts, and her blood-urea level was normal The œdema persisted despite treatment with a low-sodium diet (30 mEq daily), prednisone, and mersalyl injections Treatment with cation-exchange resin, started in September, 1956, was poorly tolerated but controlled the œdema Resins were stopped in May, 1957, and her weight increased by 2 3 kg in two weeks on a diet containing 22 mEq of sodium daily

Treatment with chlorothiazide 500 mg six-hourly was begun in June, 1957 The patient lost 2 0 kg in the next six days, with a prompt diuresis and increased excretion of sodium and chloride Since then a maintenance dose of 500 mg eight-hourly (given at first every alternate week and later for four days in each week) has controlled her œdema and body-weight There has been a tendency to hypokalæmia, and despite an extra 55 mEq of potassium daily the plasma-potassium level has on occasions fallen to 2 8 mEq per litre

Case 3—A man, aged 37, developed the nephrotic syndrome in April, 1957 His urinary output of protein is 25 g daily, serum-albumin level 1 2 g per 100 ml, and serum-cholesterol level 890 mg per 100 ml He also has hypertension (B P 140/100 mm Hg), retention of urea (blood-urea level 103 mg per 100 ml), and numerous granular casts and white and red blood-cells in his urine There had been little response to a low-salt diet and prednisone therapy

Treatment with chlorothiazide began after a control period on a low-sodium diet (22 mEq daily) 500 mg six-hourly, begun in October, 1957, caused a prompt diuresis, increased urinary excretion of sodium and chloride, and a weight loss of 4 6 kg in eleven days The intake of sodium was subsequently increased, but, when it exceeded 44 mEq daily, œdema reappeared

Case 4—A man, aged 69, developed ascites due to portal hypertension and diffuse hepatic fibrosis in August, 1955 The ascites was controlled successfully for the first sixteen months with a low-sodium diet (22 mEq daily) and weekly mersalyl injections, but over the next five months more ascitic fluid developed despite twice-weekly mersalyl injections

Treatment with chlorothiazide 500 mg six-hourly was started in June, 1957. Initially this provoked a considerable diuresis with increased urinary excretion of sodium and chloride. Two months later chlorothiazide had become ineffective, and the patient was also found to be resistant to mersalyl injections. A combination of the two treatments produced a satisfactory diuresis, and for the past three months the ascites has been controlled by continuous chlorothiazide therapy with twice-weekly injections of mersalyl 2 ml. The plasma-potassium level is 3.0–4.1 mEq. per litre despite 6 g. of potassium chloride (80 mEq. of potassium) daily.

Case 5 was a man, aged 80 years, with congestive heart-failure.

Methods

The patients were studied in hospital initially, and cases 1, 2, and 4 were subsequently followed as out-patients. They were intelligent, cooperative people who could be relied on to keep to their diets and to collect their urine accurately. Before chlorothiazide was given, there was a control period of 4–8 days on a diet of fixed sodium and chloride content. Blood-pressure and body-weight were recorded daily. Twenty-four-hour collections of urine were made, and their accuracy checked by creatinine estimations. Electrolyte and protein levels in the plasma and in the urine were determined by standard laboratory methods, and urinary glucose by the glucose-oxidase technique of Froesch and Renold (1956). In the short-term study the urine was collected by catheter, and both urine and arterial blood were kept from contact with air. The pH was estimated within 10 minutes of collection at 37°C on the pH meter described by Wynn and Ludbrook (1957). A Stadie electrode system was used and standardised with fresh phthallate buffer at pH 4.025. Titratable acidity was estimated by titration with standard NaOH to pH 7.4.

Results

Short-term Study

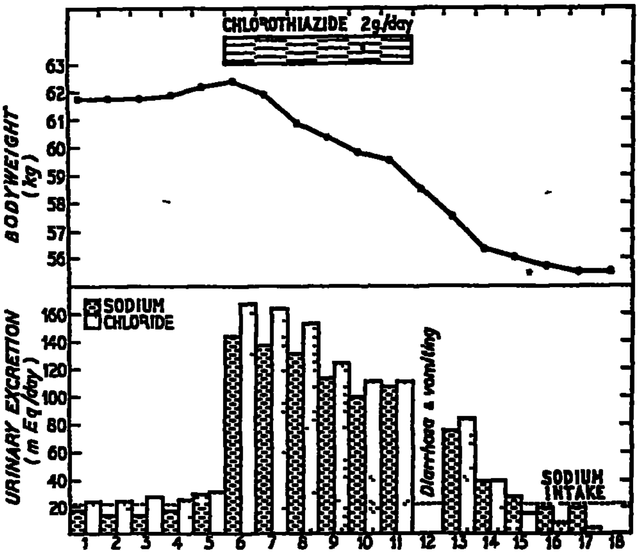

Fig. 2.—Case 1 (nephrotic syndrome): effect of initial course of chlorothiazide on body-weight and urinary excretion of sodium and chloride.

The patient selected for this had rheumatic heart-disease and benign essential hypertension. She had had congestive heart-failure, but this had responded to rest in bed, a low-sodium diet, and digitalis. She was able to concentrate the urine to sp. gr. 1.027, and her blood-urea level was 30 mg. per 100 ml. Twelve hours after the last meal control samples of arterial blood and urine were obtained. Chlorothiazide 3 g. (53 mg. per kg. of body-weight) was then given by mouth, and changes in her blood and urine were followed for the next five hours. The patient remained fasting but was encouraged to drink tap-water. The results are shown in fig. 1. There was a slight but definite transient decrease in the pH of her arterial blood, an increase in the pH of her urine, and a sharp rise in the rate of excretion of bicarbonate. The rate of excretion of hydrogen-ion diminished (decrease in titratable acid and disappearance of ammonia), and the rate of

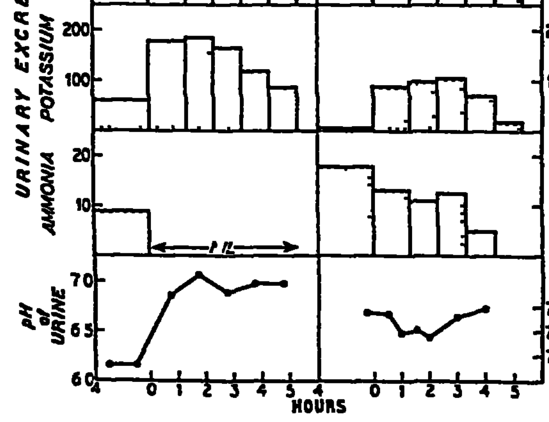

Fig. 1.—Short-term study of effects of a single oral dose of chlorothiazide 3 g. on pH of arterial blood and on volume and composition of urine.

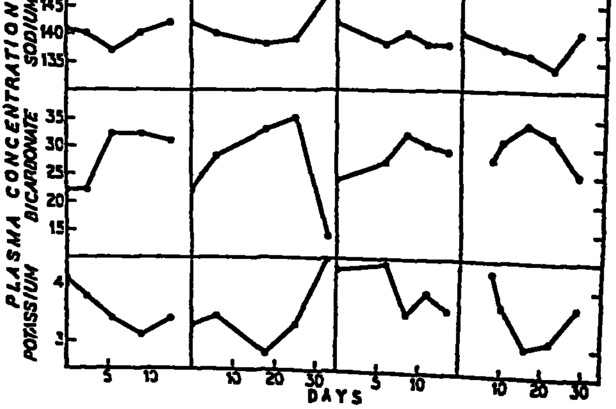

Fig. 3.—Plasma-electrolyte levels during initial period of treatment (cases 1–4).

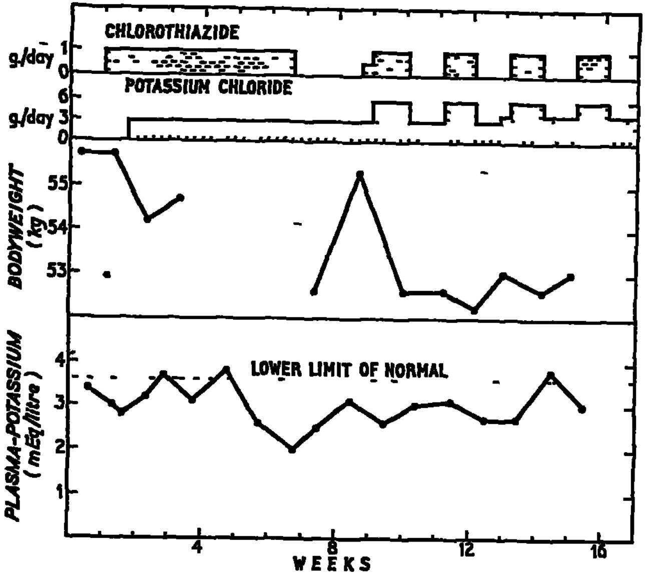

Fig 4—Case 1 (nephrotic syndrome) effect of prolonged intermittent chlorothiazide therapy on body-weight and plasma-potassium level

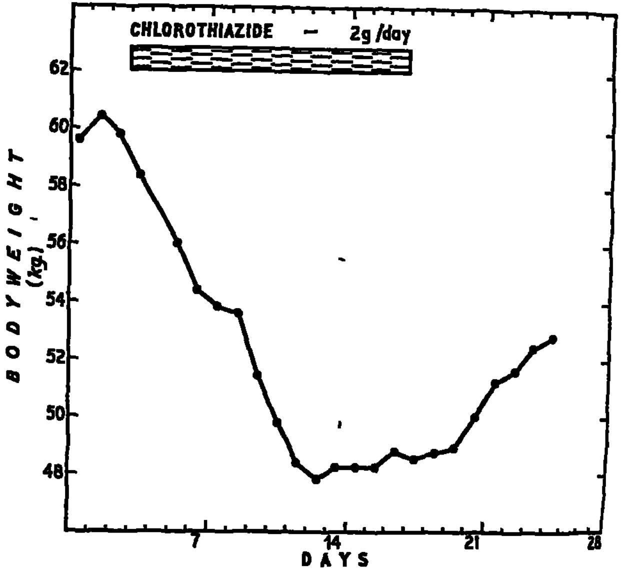

Fig 6—Case 5 (congestive heart-failure) response of body-weight to first course of chlorothiazide

excretion of potassium increased about three-fold These effects can reasonably be attributed to inhibition of renal carbonic anhydrase (Counihan et al 1954) The considerable increase in excretion of chloride is unlike the effects of carbonic anhydrase inhibitors and suggests that chlorothiazide has a separate action similar to that of the organic mercurial diuretics

Nephrotic Syndrome (cases 1–3)

Before receiving chlorothiazide all three patients were œdematous and retaining sodium despite a very low intake When chlorothiazide was given, they had a prompt diuresis with loss of weight and reduction or disappearance of œdema There was a considerable increase in the urinary excretion of sodium and chloride, the average ratio of chloride to sodium in the first six days being 1 18 1 0 (fig 2) In two of the patients this was accompanied by 25–33% increase in urinary output of potassium, in the third patient the urinary excretion of potassium decreased slightly during the first five days but increased later to an average of 27% above the control levels Changes in plasma-electrolyte levels are shown in fig 3

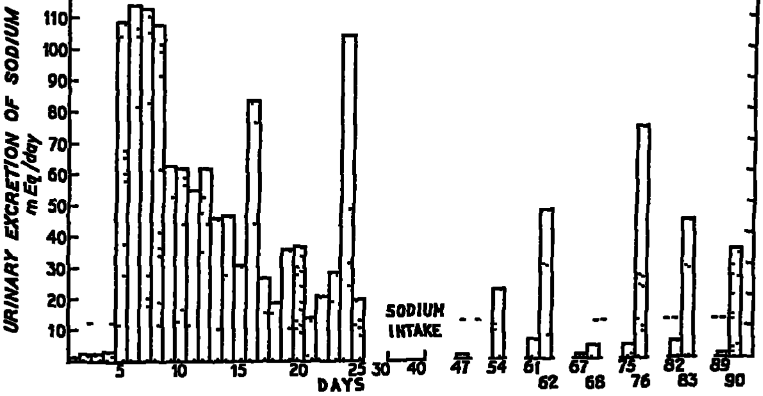

Fig 5—Case 4 (ascites due to portal hypertension) effect of chlorothiazide therapy on body-weight and urinary excretion of sodium Initial response was satisfactory, but after seven weeks patient became resistant to chlorothiazide and mersalyl given separately, although he responded when they were given together

Cases 1 and 2 have now been on treatment with a low-sodium diet and intermittent chlorothiazide for five or six months Œdema is controlled, and the patients feel well, but both have developed persistent hypokalæmia despite oral potassium supplements of up to 80 mEq daily as potassium chloride (fig 4) Studies with an increased sodium diet were made on case 3 in hospital When taking chlorothiazide he could be allowed 44 mEq of sodium daily, but, if the intake was increased to 88 mEq daily, œdema returned. It had been hoped that a diet with a higher sodium content would reduce the tendency to hypokalæmia, but the lowest plasma-potassium level (3 1 mEq per litre) occurred while he was having 88 mEq of sodium (5 1 g of NaCl) daily

During the period of observation the 24-hour urinary output of protein has remained unaltered Cases 1 and 3 had an excess of red blood-cells, white blood-cells, and granular casts in their urine, but repeated Addis counts have not shown any significant change

Specimens of urine from cases 1 and 2 were tested for glucose with glucose-oxidase tape In both patients the control urines gave negative reactions but glucose was found after chlorothiazide had been given In case 3 the glucose content of the urine was measured, during the control period he excreted 2 9–3 9 g daily, and this did not increase during the first fourteen days of chlorothiazide therapy

Cases 1 and 3 had hypertension, this was not affected by chlorothiazide

Ascites and Portal Hypertension (case 4)

This patient had gradually increasing ascites despite restriction of sodium and regular injections of mersalyl In the control period his urinary output of sodium was 1–2 mEq daily, given chlorothiazide he had at first a prompt diuresis with a considerably increased output of sodium and chloride The average urinary chloride to sodium ratio over the first six days was 1 50 1 During the initial eleven days of treatment losses of potassium exceeded the estimated intake by about 330 mEq, and at the end of this time the plasma-potassium level had fallen to 3 0 mEq per litre Subsequent details of this patient are shown in fig 5 He has become refractory to the action of chlorothiazide and to that of mersalyl although he still responds when both drugs are given together Resistant hypokalæmia has developed, but no symptoms can be attributed to it

Congestive Heart-failure

Fig 6 illustrates the dramatic response obtained with chlorothiazide in an old man with congestive heart-failure Rest in bed, a low-sodium diet, and digitalis had not relieved his breathlessness and œdema When he was given chlorothiazide, his general condition and appetite improved, but it was impossible to keep him to a low-sodium diet A steady state was finally achieved with a normal diet without added salt, chlorothiazide 2 g daily, and injections of mersalyl 2 ml twice a week His plasma-potassium level fell to 3 4 mEq per litre, and in a second patient with heart-disease the plasma-potassium level fell to 3 0 mEq per litre after 9 g of chlorothiazide had been given for four days

Discussion

The chief action of chlorothiazide appears to be to cause a rapid increase in the rate of excretion of chloride by the kidneys In this it resembles closely the diuretic action of organic mercurial compounds (Pitts and Sartorius 1950) A different effect, attributable to the inhibition of carbonic anhydrase, can be demonstrated in short-term studies This secondary action may explain why chlorothiazide produces considerable hypokalæmia, although it is unusual for mercurial diuretics to do so

In practice chlorothiazide has proved to be a most effective diuretic agent In two of our patients the diuretic action has continued for five or six months, although a third patient developed resistance in two months Compared with injections of mercurial diuretics, chlorothiazide has the great advantage of being active when taken by mouth. We have no reason to believe that it will be effective given to patients completely resistant to the action of mercurial diuretics, but in this situation a combination of chlorothiazide and mersalyl injections may provoke a diuresis

Mercurial drugs sometimes damage the renal tubules (Preedy and Russell 1953) and are often avoided in patients with renal œdema Chlorothiazide does not contain mercury and may be a safer diuretic agent in this type of case It compares favourably with the other oral diuretic drugs available It is more effective than acetazolamide (' Diamox ') and does not cause gastrointestinal symptoms as does aminometradine (' Mictine ')

Although chlorothiazide is an effective diuretic, a restricted intake of salt will continue to be necessary in many cases Most patients with œdema of renal origin, or with ascites from portal hypertension and liver damage, will continue to require very low sodium diets The intake of salt permissible in patients with cardiac œdema will vary, some will be able to tolerate a diet with " no added salt ', others will have to be restricted to a minimal intake of dietary salt despite the continuous use of chlorothiazide

Chlorothiazide seems to be remarkably well tolerated Gastrointestinal disturbances are unusual, our first patient developed diarrhœa and vomiting when first given chlorothiazide but she had had similar episodes in the past when losing œdema fluid rapidly No changes of the white blood-cells and no sensitivity reactions have been observed

The development of hypokalæmia appears to be by far the most important side-effect of chlorothiazide It is most likely in patients with resistant œdema on a low-salt intake, and, in such cases, even large supplements of potassium chloride may fail to keep the plasma-potassium level normal The dangers of hypokalæmia are difficult to assess We have not met with any clinical features that can be attributed to it Hypokalæmia may potentiate the toxic effects of digitalis on the heart (Lown et al 1951), and this may well prove to be the most serious danger of chlorothiazide therapy The possibility of renal damage due to prolonged depletion of potassium should also be considered (Relman and Schwartz 1956) If a patient has œdema that is persistent enough to need both severe restriction of sodium (44 mEq or less daily) and chlorothiazide therapy (either continuous or intermittent), we would regard it as essential to have regular estimations of plasma-potassium concentrations Initially these should be made at weekly intervals, and suitable supplements of potassium chloride should be given

Summary

A new oral non-mercurial diuretic, chlorothiazide, has been used successfully in patients with the nephrotic syndrome, ascites due to portal hypertension, and congestive heart-failure Two patients with the nephrotic syndrome have now been controlled satisfactorily for five or six months

Chlorothiazide therapy was followed by a considerable and prompt diuresis, with increased excretion of sodium and chloride The mode of action and the therapeutic response resemble those of the mercurial diuretics A subsidiary effect suggesting inhibition of carbonic anhydrase was observed in a short-term study

Chlorothiazide caused hypokalæmia which was difficult to control with oral potassium supplements No other side-effects have so far been observed

We wish to thank Messrs Merck, Sharp & Dohme, Ltd, Hoddesdon, Herts, for supplies of chlorothiazide ('Saluric'), the staff of the routine laboratories of the Courtauld Institute of Biochemistry of the Middlesex Hospital for the plasma-electrolyte estimations, Dr E K Westlake for help with the pH determinations, Mr V K Asta for preparing the figures, and the Clinical Research Committee of the Middlesex Hospital for the provision of laboratory facilities and a personal research grant to J D N N

CONTROL OF TREATMENT IN *MYXŒDEMA* BY ELECTROCARDIOGRAPHY

PAUL C GIBSON
M D , B Sc Lond , M R C P

LATELY PHYSICIAN TO TORBAY HOSPITAL, DEVON

> The recognition of cardiac symptoms in cases of myxœdema that have gone for long periods without treatment is of great practical importance, for when heart disease is present treatment with thyroid extract must be carried out with great care —
> G R MURRAY, 1897

THIS warning, issued at the outset of thyroid treatment for myxœdema, has been fully justified in the experience of the past sixty years but is still largely ignored It is the purpose of this paper to define the danger of indiscriminate dosage and to show the value of electrocardiography in controlling treatment

It must be assumed that every patient with obvious myxœdema has heart-disease, either from atheroma or from the involvement of the myocardium in the disease itself, hence every patient is in danger from careless treatment Brewer (1951) notes the extreme scarcity of necropsy reports on untreated cases of myxœdema and thinks this is due to the introduction of thyroid treatment in 1891 I doubt if this really explains it, for I am convinced that untreated myxœdema still abounds The twelve cases I am recording represent less than half of the patients I have treated during the past ten years These twelve were typical and recognisable at sight, yet only three had had any previous treatment One of them was interesting in this respect because, although the clinical picture was typical and recognisable, it was not recognised, even in hospital, until the electrocardiogram pointed the way It showed how easily even a typical case may escape recognition unless this possibility is constantly borne in mind

Necropsy records of treated cases, though not plentiful, are readily found Brewer (1951) recorded one, and Smyth (1938) collected five from American literature and records one of his own In every case death was due to acute coronary insufficiency attributed to treatment with thyroid If untreated myxœdema is as prevalent as it seems to be and necropsy records are only to be found in treated cases, it suggests that treatment can be more deadly than the disease

A great difficulty in selecting safe and adequate dosage has been the lack of a reliable means of assessing adequacy Zondek (1918) recorded the typical electrocardiographic changes in myxœdema, but, I believe, this observation has not come into regular use for controlling treatment. This method of control was used in all my cases

The twelve patients in this series all attended my clinic at Torbay Hospital in 1945-57 Only those with a significantly lowered basal metabolic rate (B M R) are included The year of their first visit is noted with their ages in table I Every patient was seen for final assessment in 1957

TABLE I—DOSAGE OF THYROID (GRAINS)

Case no	Sex	Date	Age (yr)	B M R (%) *	Previous thyroid treatment	Daily dose (grains)		Final assessment	
						A	B	Health	Dose
1	M	1947	43	−30	None	1½	2	Good	2
2	F	1954	70	−31	None	1½–6	1	Hypo-thyroid	1
3	M	1952	48	−6	None	¼	½	Very good	½

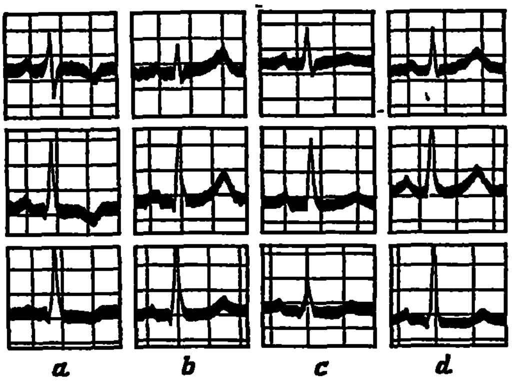

Fig 1—Serial electrocardiograms of case 1 a, Nov 17, 1947 b, March 3, 1948 c, Jan 25, 1957 d, April 11, 1957

He had had some chest pain on exertion, so an electrocardiogram was taken (fig 1*a*) It suggested myxœdema, and in the light of this the clinical picture was seen to be typical The patient was started at once on thyroid gr 1, gradually increased to gr 2 by Jan 7, 1948 The swellings quickly subsided, and by March 3, 1948, the T voltage was fully restored (fig 1*b*) The patient was not seen again for 10 years, when he was sent for on Jan 25, 1957 The painful swellings of his arms had returned, he complained of feeling cold and breathless, and T voltage was reduced (fig 1*c*) He said that 5 years previously the dosage of thyroid was reduced to gr 1 daily because of palpitation He had taken this dose since It was now increased to gr $1^1/_2$, and by April 11, 1957, his arms were normal and T voltage increased (fig 1*d*) He still felt cold and breathless, so the original maintenance dosage of gr 2 daily was restored He has kept well on this since It was remarkable how closely the rise and fall of the T waves corresponded to the disappearance and reappearance of localised patches of myxœdema

Case 2 —A woman, aged 70, was admitted to hospital on Aug 30, 1954, during my absence, with advanced myxœdema She was at once given thyroid gr $1^1/_2$ daily After 10 days this dosage was increased to gr $4^1/_2$, though she had already begun to complain of anginal pain,[9] which she had never had before On Sept 22, 1954, the dosage was increased to gr 6 daily Next day the patient had an attack clinically resembling coronary thrombosis The dosage was reduced to gr 3 daily, and on Sept 28, 1954, treatment with thyroid was stopped On Oct 4, 1954, the patient was still having angina at rest, but there were no signs of heart-failure The electrocardiogram (fig 2*a*) showed T inversion in all leads superimposed on the changes of myocardial ischæmia Treatment with thyroid gr $^1/_4$ daily was started, and increased to gr $^1/_2$ on Oct 11, 1954 She tolerated this, but an electrocardiogram taken 3 weeks later (fig 2*b*) showed that it was inadequate She kept on this dose for about a year, and it was then increased to gr 1 daily She was comfortable with this dose but could not tolerate gr $1^1/_2$ daily, so gr 1 daily was accepted as her maintenance dosage as an inevitable compromise With this she kept reasonably well and could do all that she wanted to When seen again on March 4, 1957, she was obviously hypothyroid, and electrocardiography still showed the typical T inversion (fig 2*c*), but, when the dosage was increased to gr $1^1/_2$ daily, she got more pain She is still taking gr 1 daily

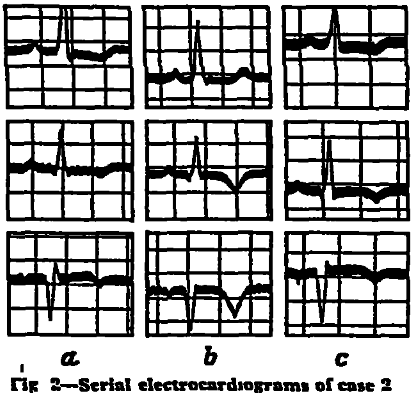

Fig 2—Serial electrocardiograms of case 2 a, Oct 4 1954 b, Oct 29, 1954 c, March 4, 1957

Case 3 —A man, aged 43, underwent in 1947 partial thyroidectomy for thyrotoxicosis with auricular fibrillation After operation normal rhythm was restored, and he was soon leading a very active life as a fruit farmer At the age of 48 he came to see me on Aug 28, 1952, because for the past 2 years he had become increasingly tired and had had three prolonged attacks of tachycardia with general trembling and lately he had been having chest pain on exertion He said that during the past six months he had lost a stone in weight Clinical examination revealed nothing of interest, and his electrocardiogram (fig 3*a*) was passably normal Further investigation revealed that his B.M.R was −6%, basal pulse-rate 56, basal blood-pressure 112/88 mm Hg, and blood-cholesterol level 235 mg per 100 ml On Sept 14, 1952, he was started on thyroid gr $^1/_4$ daily, and by Nov 7, 1952, his electrocardiogram (fig 3*b*) showed a striking rise in T voltage The same dosage was continued, but 2 months later he began to feel tired again, and so it was increased to gr $^1/_2$ daily He has kept quite well on this dosage, doing exceptionally heavy work at times This case shows that a single electrocardiogram may be misleading It was the response of the T waves to thyroid that was pathognomonic

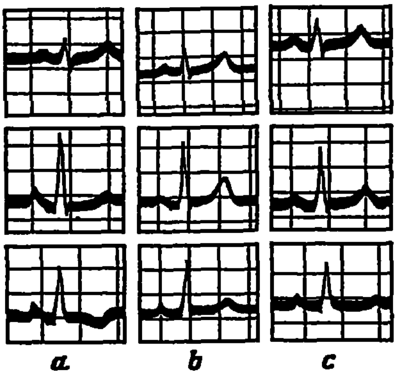

Fig 3—Serial electrocardiograms of case 3 a, Aug 28, 1952 b, Nov 7, 1952: c, Feb 1, 1957

Case 4 —A man, aged 55, was admitted to hospital on March 27, 1950, with advanced myxœdema and a grossly enlarged heart T T D 17 5 cm He was started at once on thyroid extract gr 2 daily 8 days later he had an alarming attack of acute pulmonary œdema The dosage of thyroid was reduced to gr $^1/_2$ daily, and he promptly recovered On May 26, 1950, he was much better, and the size of his heart was normal (total transverse diameter 12 5 cm) The dosage of thyroid was increased to gr 1 daily and 4 months later to gr $1^1/_2$ daily He kept on this dosage for 6 years During this period he had a series of " thrombotic " events, left quadrantic blindness (April 27, 1950), right hemiplegia with aphasia (July 12, 1953), and acute coronary insufficiency (Dec 25, 1956) The coronary attack was short and sharp, with complete recovery after 24 hours The patient was kept in bed for 2 weeks but was afebrile and symptomless The electrocardiograms were obscured by extreme left axis-deviation which persisted after the heart size was restored to normal The day after the coronary attack there was slight R-T deviation in lead 4 The patient has had no anginal pain since and no residual heart weakness After the coronary attack the dosage of thyroid was reduced to gr 1 daily The patient has kept well on this since

Case 5 —A man, aged 56, who had been under treatment for progressive osteo-arthritis since 1933, begin to have angina of effort in February, 1945 In the following September myxœdema was discovered, and he was given thyroid gr 3 daily His anginal pain became worse and now came on at rest, sometimes he had three or four attacks a day About a month after starting treatment with thyroid he had an attack considered to be coronary thrombosis, but no electrocardiogram was taken Thyroid was stopped, and the pain then lessened, but during the next 6 weeks the patient became progressively more myxœdematous On Nov 24, 1945, he was admitted to Torbay Hospital, obviously myxœdematous His B M R was

—25%, and his electrocardiogram showed left axis-deviation with flattening of T_1 and inversion of T_2 He was still having angina of effort On Dec 20, 1945, treatment with thyroid gr 1/2 was started He improved steadily and on Feb 22, 1946, was having no serious pain, but his electrocardiogram 2 weeks later showed little change The dosage of thyroid was increased to gr 1 daily, which he tolerated quite well Because of distortion by left axis-deviation the electrocardiogram was difficult to interpret; so on April 22, 1946, his B M R was estimated again, and found to be —16% The dosage of thyroid was gradually increased to gr 2 by Jan 4, 1947 On April 19, 1947, the B M R was +7%, but he was having a lot of anginal pain, so the dosage was reduced to gr 1 1/2 daily At his last visit, on Aug 2, 1947, he was still complaining of pain, though the T voltage was much improved (table II) He was advised to revert to thyroid gr 1 daily He then left the district On Jan 21, 1957, his doctor reported that he was still on the same dosage of thyroid, and was getting some effort pain, but his chief trouble was the arthritis

Case 6—This case illustrates a special risk from overdosage with thyroid in *myxœdema secondary to thyroidectomy* A woman, aged 54, was admitted to hospital on Jan 9, 1956, with a large toxic goitre She had been fibrillating for about a year but had no obvious signs of heart-failure Her B M R was +43% She underwent complete thyroidectomy on Jan 17, 1956, followed by a full course of radiotherapy because the goitre was malignant On March 28, 1956, her appearance and behaviour suggested myxœdema, her B M R was —3%, and her electrocardiogram showed inversion of T in all leads Treatment with thyroid gr 1/4 daily was started on April 2, 1956, and increased to gr 1/2 daily on Aug 29, 1956 Her principal symptom was depression, which was improving slowly but steadily On Oct 31, 1956, the dosage of thyroid was increased to gr 1 daily 3 months later the depression had passed and the electrocardiogram showed considerable improvement in T voltage, but the P–R conduction time was 0 24 sec, and the patient felt cold and was breathless on hills The dosage of thyroid was increased to gr 1 1/2 daily and a month later to gr 2 daily 2 months later she felt well but was fibrillating Treatment with thyroid was stopped, and quinidine was given, which converted the fibrillation to flutter In spite of full digitalisation, which induced nausea and vomiting, the flutter persisted, though at a slower ventricular rate It seemed likely that the myocardium was damaged, so it was decided to let the flutter be and to control the ventricular rate with minimal doses of digitalis In retrospect one can see that it would have been wiser to keep the thyroid dosage at gr 1 daily, but at the time I thought her thyroid had been so thoroughly destroyed that she might need a larger dose than usual

Discussion

Sensitivity to Thyroid

It is known that patients with myxœdema are apt to be hypersensitive to thyroid extract, the more advanced the disease the greater is this tendency This sensitivity is expressed as anginal pain In the angina of myxœdema the pattern of pain may be confused by treatment Before treatment it usually appears as an effort pain, which subsides as treatment becomes effective After treatment there may be added a pain with distinctive qualities which is aggravated by treatment Seven of my patients had angina of effort relieved by treatment Two of them (cases 2 and 5), after treatment had started, had spasms of pain at rest, sometimes three or four attacks a day, usually of short duration but sometimes lasting several hours This pain was not relieved by trinitrin and was aggravated by thyroid Both of these patients had started with grossly excessive dosage, and both of them had attacks indistinguishable clinically from coronary thrombosis But in these attacks, though the pain was severe, collapse was minimal, and the attacks subsided quickly when treatment with thyroid was stopped, leaving little evidence of persistent myocardial damage

The most favoured explanation of these coronary attacks following treatment is that they are due to a relative vascular insufficiency induced by a rise in the metabolic rate It is difficult to reconcile this theory with the typical lability of the attacks, which may come and go several times in a day, moreover it is inconsistent with an experience recorded by Oliver and Boyd (1957), who used the acetyl analogue of triiodothyronine to reduce cholesterinæmia in a group of twelve men with known coronary disease Two of them had severe angina of effort during this treatment, although the B M R was not raised

A notable feature in the necropsies referred to above was myocardial infarction without thrombosis Brewer's (1951) patient died suddenly in a manner suggesting coronary thrombosis, but no thrombus was found, Smyth (1938) records a case in which a large area of necrosis was found in the myocardium without any evidence of thrombosis He also says that, in three of the five other necropsies reviewed by him, on patients who had met a coronary death while under treatment, no thrombus was found Wood (1956) refers to myocardial infarction without thrombosis as occurring in myxœdema when treated too vigorously with thyroxine If these anginal crises and sudden deaths under treatment are sensitivity reactions, this could explain the capricious nature of the angina and infarction without thrombosis, because one can readily associate such coronary sensitivity with reversible occlusion in terms of intimal swelling and vasospasm

The Electrocardiograms

On the whole the behaviour of the T wave fulfilled expectation When the electrocardiogram is distorted by coronary disease, as in case 2, or by extreme axis-deviation, as in cases 4 and 5, it is not easy at first to recognise the T-wave changes of myxœdema, but in serial electrocardiograms these were recognisable in all cases When the electrocardiogram is not distorted, the changes induced by myxœdema may be pathognomonic, but what clinches the diagnosis is the response of the T-waves to thyroid The chief value of the electrocardiogram is in the control of treatment, because by its use one can judge the adequacy of dosage

Dosage of Thyroid

Initial dosage—After my experience in case 4, when gr 2 induced acute ventricular failure, I decided to use gr 1/4 as a standard initial dose This later proved to be adequate, even in case 10, whose R M R was the lowest of the series When the change in T voltage (table II) was effected, she was still on gr 1/4 daily In Brewer's (1951) case sudden death followed an initial dose of gr 3/4 If gr 1/4 is adequate, there is no reason for starting with more

Maintenance dosage—This was the dosage reached when symptoms had cleared and T voltage was fully restored From these results it seems to be rarely necessary to give more than gr 2 daily for maintenance In this series the thyroid needs bore no relation to the B M R In case 10, with the lowest B M R, the maintenance dosage was only gr 1/2 whereas in case 8, in which the B M R was only —15%, gr 2 daily was needed to keep her free from symptoms

Final Assessment

Every patient was re-examined in 1957 Three of them were hypothyroid In two of these (cases 1 and 9) the maintenance dosage had been reduced, both of them improved promptly when the original maintenance dosage was restored The other patient (case 2) cannot tolerate an adequate dosage and is still hypothyroid The prominent symptoms in these hypothyroid cases was feeling cold and breathlessness This cold feeling was a well-defined symptom, the patients never felt warm, even in bed it is usually an early symptom and is the last to go Breathlessness was prominent in most of the patients before to develop after immoderate consumption of alcohol and can also be caused by numerous chemical poisons (Sheehan and Moore 1952) Cortical necrosis was suspected clinically in this patient and confirmed post mortem

Drugs

Our only experience of acute renal failure after drug administration has been with the sulphonamide group These are known to give rise to renal failure from obstruction by crystalline deposits and epithelial debris in the urinary pathways and from hypersensitivity lesions in the kidneys, particularly acute tubular necrosis and renal arteritis

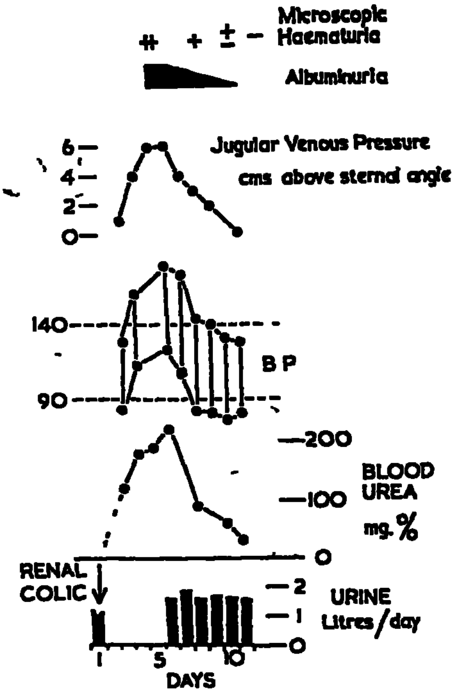

Fig 2—Case 9 rise in blood-pressure and venous pressure probably due to overloading with water and salt during anuria due to sulphonamide obstruction On the 13th day the effective renal plasma flow (p-aminohippurate clearance) was 601 ml per min and the glomerular filtration-rate (thiosulphate clearance) 93 ml per min

Sulphonamide Obstructive Anuria

We have seen a good many cases of sulphonamide crystalluria with hæmaturia and renal colic Only 5 patients, however, had anuria of any note (cases 9–13 and fig 2) 1 patient developed cystitis following urethral catheterisation and, when cystoscopy was done, the ureteric orifices could not be located and the cystoscope was pushed through the friable bladder wall The patient was moribund from peritonitis when we saw him The 4 other patients appeared to have spontaneous diureses When diuresis appeared to start after unsuccessful attempts at ureteric catheterisation, it was our impression that this was due to the moving about of the patient on the journey to the theatre Kolff (1955) emphasises that a rough trip in an ambulance is a good therapeutic measure for such patients Our present policy is to treat conservatively and to avoid urological manipulations Hopper and Partridge (1950) point out that in 82 out of 84 collected cases of sulphonamide obstructive anuria the patients recovered The average onset of diuresis was at 3 1 days and the range was from one to eleven days

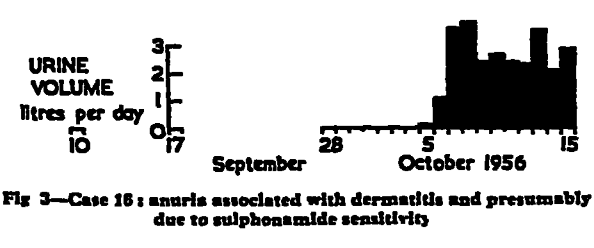

Fig 3—Case 16: anuria associated with dermatitis and presumably due to sulphonamide sensitivity

Sulphonamide-sensitivity Anuria

3 patients developed acute renal failure apparently as a sensitivity reaction to sulphonamide drugs (cases 14–16 and fig 3) They all had associated dermatitis, and in 1 case this started after exposure to the sun The renal failure was more severe, and the anuria of longer duration, than in sulphonamide obstructive anuria 2 patients recovered on conservative management The 3rd patient died partly from rather poor management of the anuria and partly from pyelonephritis superimposed on the tubular necrosis and possibly due to ureteric catheterisation

Renal failure due to potentially hæmolytic drugs—e g, quinine and mephenesin—has been discussed in a previous paper on anuria following intravascular hæmolysis (Bull et al 1957)

Anuria has been noted to follow exposure of the kidney to radio-opaque material—e g, in aortography (Dormandy et al 1957) and in retrograde pyelography with pyelorenal backflow (Grieve and Lowe 1955)—but these complications are rare

Discussion

The pattern of disturbed renal function in our cases of acute tubular necrosis due to poisoning and to sulphonamide sensitivity was the same as in our cases of concealed accidental hæmorrhage, intravascular hæmolysis, and criminal abortion, which are the other most common causes of acute tubular necrosis in our series Despite the varying histological pictures and different types of tubular damage described by Oliver et al (1951) we have failed to show any functional differentiation between cases of tubular necrosis due predominantly to nephrotoxins and cases due predominantly to renal ischæmia (Bull et al 1950, Lowe et al 1954, Emslie-Smith et al 1956) As regards sulphonamide obstructive anuria we have studied renal function in only 1 case (case 9), in which there was a much earlier recovery of function than would be expected in tubular necrosis (fig 2)

Acute renal failure due to poisonings and sulphonamide (either obstruction or sensitivity) should carry a high recovery-rate with adequate treatment. The 2 deaths among our sulphonamide cases were probably avoidable In mercury poisoning there is very extensive tubular necrosis (Allen 1951), but its reversibility is shown by the excellent recovery made by our 3 patients The death due to hydrochloric-acid poisoning was due to associated damage of the respiratory and alimentary tracts, renal failure being incidental, and the death due to oxalic-acid poisoning was unexplained and took place when the patient was in the recovery phase of the renal lesion Our cases of phenol poisoning have been mild, and we have not encountered a fatal case

Summary

Of 5 cases of acute tubular necrosis due to poisons 3 were due to mercury and 1 each to oxalic and hydrochloric acids The patients with mercurial tubular necrosis recovered, but the 2 others died Only very mild cases of phenol and turpentine poisoning were encountered, and none of the patients had anuria. 2 chronic alcoholics died in renal failure after drinking bouts one had lobar pneumonia and acute tubular necrosis, the other had renal

cortical necrosis There were 5 cases of sulphonamide obstructive anuria and 3 of sulphonamide sensitivity with renal failure, 1 patient in each group died

Appendix

Case 1 —A woman, aged 36, was prescribed mercuric-chloride tablets for use in vaginal douching for vaginitis She used too concentrated a solution and developed a severe vaginal irritation with vomiting, diarrhœa, and a brisk diuresis that was followed within a few hours by anuria Dimercaprol was not given until the fourth day of anuria She was treated by the intragastric regime (Bull et al 1949) and with the artificial kidney on the tenth day of anuria Her blood-urea level rose to a maximum of 325 mg per 100 ml, and diuresis developed on the twelfth day She made a good clinical recovery

Case 2 —A woman, aged 21, swallowed some mercuric oxide in a suicidal attempt Faintness, vomiting, and anuria followed She was treated with gastric lavage but had no dimercaprol Anuria persisted for eleven days, and her maximal blood-urea level was 380 mg per 100 ml She was treated conservatively by the intragastric regime and made a good clinical recovery Convalescence was delayed by disturbance of her central nervous system in the early and late diuretic phases The chief features were tremor, ataxia, and dysarthria of the type seen in industrial mercury poisoning Her incoordination is evident from her handwriting (fig 1)

Case 3 —A woman, aged 23, swallowed some "hair-curling tonic" (which contained mercuric chloride 24 g per packet) She collapsed with immediate abdominal pain and was taken to hospital, where her stomach was washed out She had bloody diarrhœa, vomiting, and anuria Dimercaprol was not given until the second day With careful conservative management she made a good recovery after eight days' anuria

Case 4 —A woman, aged 30, was admitted to hospital some hours after swallowing a teaspoonful of oxalic-acid crystals Her stomach was washed out, and she had an intravenous infusion of noradrenaline in physiological saline solution for shock She had anuria and then severe oliguria, and her blood-urea level rose to 450 mg per 100 ml on the sixteenth day Thereafter she entered the early diuretic phase, and her blood-urea level began to fall Treatment was by intravenous infusion of hypertonic glucose into the inferior vena cava and with retention enemata of sodium-charged cation-exchange resin Unfortunately she had an unexplained profound circulatory collapse on the twenty-second day and died Necropsy confirmed the diagnosis of acute tubular necrosis

Case 5 —A man, aged 54, was admitted to hospital some hours after swallowing an unknown quantity of hydrochloric acid in a suicidal attempt On admission emergency tracheotomy was done for laryngeal obstruction due to œdema He was very restless and had gross excoriation in the mouth and generalised râles in the lungs His blood-pressure was 120/90 mm Hg Since he did not pass urine that day he was catheterised at night, 300 ml of dark brown urine was obtained, and its specific gravity was 1 020 Only small quantities were obtained by catheter from that time until death forty-eight hours later, the total amounting to 200 ml The urine was dark, of specific gravity 1 010, and contained pigmented casts The blood-pressure remained between 110/70 and 140/90 mm Hg until shortly before death At necropsy there were gross signs of acid erosion in the air passages and upper gastro-intestinal tract, pulmonary œdema, and bronchopneumonia Histologically the kidneys showed acute tubular necrosis, with a few pigment casts in the collecting tubules

Case 6 —A woman, aged 61, drank half a cupful of 'Lysol' in a suicidal attempt She was found unconscious and was brought into hospital, where she recovered consciousness rapidly Her general condition was good, her blood-pressure was 145/70 mm Hg, and there were brownish staining on her chin and ulceration in her mouth The first samples of urine showed carboluria and were well concentrated (urinary urea 1800–3200 mg per 100 ml) Treatment consisted of olive oil orally, prophylactic penicillin, and careful water and electrolyte balance Urine volume was on the low side for a few days, the blood-urea level fell from 60 mg per 100 ml on the second day to 20 mg per 100 ml on the fifth day She recovered quickly

Case 7 —A man, aged 42, was found semiconscious in his house and brought into hospital He had been a very heavy drinker for years and had been indulging excessively during the past month He had had some pain in his left chest for forty-eight hours On examination he was drowsy and breathless, his blood-pressure was 80/50 mm Hg, and there were signs of left lower lobar pneumonia He passed 180 ml of urine on the first day There was heavy proteinuria, and many red cells and a few granular and cellular casts were seen microscopically in the spun deposit He remained severely oliguric, and his blood-urea level rose from 96 mg per 100 ml on the second day to 496 mg per 100 ml on the seventh day in hospital He died on the eighth day Necropsy showed resolving left lower lobar pneumonia, pulmonary œdema, and several hæmorrhages into the trunk muscles The kidneys showed typical lesions of acute tubular necrosis affecting the distal nephrons and severe hydropic swelling of the proximal tubular cells There was also very mild glomerulitis

Case 8.—A man, aged 27, was found unconscious in a chemist's shop and brought into hospital He had been drinking heavily for some months and had consumed a bottle of whisky during the previous day Examination of the cerebrospinal fluid and radiography of the skull were normal He recovered consciousness but was hallucinated and required sedation with paraldehyde Despite good general condition and a blood-pressure of 124/64 mm Hg he had very severe oliguria, with red cells and hyaline and granular casts in his urine He developed epileptiform fits, and his blood-urea level rose to 155 mg per 100 ml on the third hospital day, when he died Necropsy confirmed the clinical diagnosis of renal cortical necrosis

Case 9 —A man, aged 34, had 30 g of sulphadiazine during outpatient treatment of gonorrhœa He developed renal colic, hæmaturia, and then anuria Two attempts at ureteric catheterisation, one under spinal anæsthesia, failed, and after two days' anuria he was transferred to our care He had been grossly overloaded with salt and water and had developed hypertension, increased jugular venous pressure, basal crepitations in the lungs, and œdema On the fourth day he was cystoscoped under local anæsthesia His bladder mucosa was injected and œdematous A ureteric catheter was passed a few centimetres up the left ureter, and some epithelial debris was removed No crystals were seen microscopically In the next twelve hours he passed 275 ml urine and subsequently he made a good clinical recovery Data are shown in fig 2 Note that renal function tests on the thirteenth day were near the lower limit of normal

Case 10 —A man, aged 25, had a vague illness characterised by anorexia, vomiting, and abdominal pain He received sulphadiazine 20 g in four days and on the fourth day developed hæmaturia and oliguria He was admitted to hospital and in the next four days passed only 275 ml of bloodstained urine He was transferred to our care, and on the fifth day of anuria cystoscopy was done under low spinal anæsthesia His bladder mucosa was œdematous, and the ureteric orifices were not located On return to the ward he started to pass urine, and in the next twelve hours 4200 ml was recovered His highest blood-urea level was 93 mg per 100 ml on the fifth day He made a good clinical recovery

Case 11 —A man, aged 63, was treated with sulphamezathine 24 g in four days for a chest infection and on the fourth day developed loin pain, hæmaturia, oliguria, and then anuria He was admitted to hospital next day, where bladder catheterisation confirmed anuria He was cystoscoped two days later, but the procedure was abandoned after the patient developed severe shock The cystoscope had perforated the œdematous inflamed bladder wall, but this fact was not appreciated at the time Paralytic ileus developed, and he was transferred to our care He died on the sixth day of anuria Necropsy showed peritonitis due to traumatic perforation of the bladder wall

Case 12 —A man, aged 45, was treated with sulphamezathine 12 g for tonsillitis and then developed renal colic, hæmaturia, and then anuria An attempt at ureteric catheterisation failed on the fifth day, and he was transferred to our care Spontaneous diuresis developed on the sixth day, however, and he made a good clinical recovery His highest blood-urea level was 130 mg per 100 ml on the fifth day

Case 13 —A woman, aged 42, was treated for a chest infection with sulphamezathine 19 g in three days She then developed renal colic, hæmaturia, and anuria She remained anuric for three days and then had a rather gradual diuresis Her highest blood-urea level was 106 mg per 100 ml on the fifth day

Case 14 —A woman, aged 54, was treated with 12 g of a sulphonamide drug (the exact preparation was unknown) for an upper respiratory infection She developed a skin rash and oliguria, and the drug was stopped She was admitted to hospital three days later and was treated with alkalis and intravenous fluids Ureteric catheters were passed and the renal pelves washed out with bicarbonate solution There was no evidence of ureteric obstruction, and no crystalluria was evident On the eighth day of anuria she was transferred to our care She was drowsy and œdematous and had bronchopneumonia and severe dermatitis She died on the tenth day Necropsy showed staphylococcal bronchopneumonia, acute tubular necrosis, pyelonephritis, and multiple abscesses in the left kidney Tubular necrosis was considered to be due to sulphonamide sensitivity, and the pyelonephritis and renal abscesses were thought to be superimposed lesions due to infection following ureteric catheterisation

Case 15 —A man, aged 65, was treated with phthalylsulphathiazole preoperatively for rectal carcinoma Dermatitis and oliguria developed Cystoscopy was performed , only the right ureter could be catheterised, and no abnormality was found The blood-urea level, which had been 25 mg per 100 ml on admission, rose to 254 mg per 100 ml , and then with spontaneous diuresis, fell to 74 mg per 100 ml At this time the patient's general condition was fair, and he had an exacerbation of chest infection Palliative colostomy was done after preparation with blood-transfusion and breathing exercises

Case 16 —A woman, aged 62, developed diarrhœa, and after eight days she consulted her doctor, who prescribed sulphaguanidine Next day severe dermatitis began while she was sitting in the sunlight The rash spread, and the drug was stopped after three days Two days later left basal pneumonia developed, and was treated with erythromycin On the twelfth day after starting drug therapy she had anuria, and on the sixth day of anuria she was admitted to hospital Diuresis began two days later, and her blood-urea level fell rapidly from its highest level of 230 mg per 100 ml (fig 3) No crystals were present in freshly voided urine at the onset of diuresis In the early diuretic phase there were poor concentration of urine and failure of conservation of sodium and potassium On the twelfth day after onset of diuresis a water load of 1 litre led to a maximal flow of 9 ml of urine a minute, which was reduced to 1 ml a minute after the intramuscular injection of 5 units of posterior pituitary extract, thereby showing the return of tubular function Patch-testing during convalescence confirmed sulphonamide sensitivity The patient's daughter, like her mother, developed an acute skin eruption after treatment with sulphonamide , neither had been treated before with sulphonamide

We are grateful to Dr Robert Semple for permission to include case 8

AN ATYPICAL CARCINOID TUMOUR SECRETING 5-HYDROXYTRYPTOPHAN

M Sandler
M B Manc , M R C P
LECTURER IN CHEMICAL PATHOLOGY,
ROYAL FREE HOSPITAL SCHOOL OF MEDICINE, LONDON

P J D Snow
M D Manc , M R C P
SENIOR REGISTRAR, UNIVERSITY DEPARTMENT OF MEDICINE,
MANCHESTER ROYAL INFIRMARY

THE syndrome associated with metastasising argentaffinoma has now been well documented, and it seems likely that many of the manifestations are due to an excess of 5-hydroxytryptamine elaborated by the tumour Among the many cases published, a few, including the third patient described by Snow et al (1955), present certain atypical features Prompted by the similarity to another atypical patient described by Smith et al (1957), we have reinvestigated this patient Our findings suggest that he may belong to a distinct clinical group in which the tumours produce 5-hydroxytryptophan instead of 5-hydroxytryptamine

Case-report

A detailed clinical description of this man, aged 45, has already been published (Snow et al 1955) To summarise, flushing attacks precipitated by food and particularly by alcohol had been present for more than twenty years The flush was patchy and bright red, and could be attenuated by anti-histamine therapy Diarrhœa had never been a feature The patient was first observed four years ago, when his hard enlarged palpable liver was found at laparotomy to be full of metastases from a small primary tumour in his stomach The hepatic enlargement has remained unchanged up to now, and there has been no deterioration in his general condition, which remains excellent His main complaint continues to be of intermittent attacks of pain caused by a duodenal ulcer, whose presence was confirmed at the laparotomy Additional radiological investigations since the previous report on this patient have included intravenous pyelography and a skeletal survey, neither of which has revealed any abnormality

Further Investigations

Methods

Urinary 5-hydroxytryptamine was estimated in our respective laboratories either by the colorimetric method of Udenfriend et al (1955b) or by the same 1-nitroso-2-naphthol colour reaction after adsorption on a column of 'Amberlite IRC 50' and elution with sulphuric acid, a standard being carried through the whole procedure The results obtained by the two methods were in close agreement Urinary 5-hydroxyindoleacetic acid was estimated by the method of Udenfriend et al (1955a) or by the method of Macfarlane et al (1956), both of which gave comparable results "Total 5-hydroxyindoles" were measured as the colour reaction produced by 1-nitroso-2-naphthol with the unextracted urine with 5-hydroxyindoleacetic-acid standards Chromatography of the

TABLE I—PARTITION OF 5-HYDROXYINDOLES IN URINE FROM BLADDER

Specimen no	1		2		3
—	mg per g of creatinine	mg per 24 hr	mg per g of creatinine	mg per 24 hr	mg per g of creatinine
"Total 5-hydroxyindoles"	110	110	99 4	117 0	98
5-Hydroxytryptamine	18	18	20 4	24 0	20
5-Hydroxyindoleacetic acid	43	43	50 3	59 4	47
Balance = 5-hydroxytryptophan	49	49	28 7	33 6	31

urine for indoles was kindly carried out by Dr C E Dalgliesh (Dalgliesh 1955, 1956) Indole chromatography was also done by the method of Jepson (1955) on ultrafiltered desalted serum and on urine The presence of 5-hydroxytryptamine on chromatograms was confirmed by the method of Jepson and Stevens (1953)

This histamine content of the urine was kindly estimated by Dr R S Stacey, using the method described by Roberts and Adam (1950)

Chromatography

Chromatographic examination was carried out on bladder urine and on separate specimens obtained from each ureter 5-Hydroxytryptophan was present in all the specimens, and 5-hydroxytryptamine, 5-hydroxyindoleacetic acid, and unknown slow-running Ehrlich-reacting spots, presumed to be conjugates, were also found in bladder urine There were insufficient 5-hydroxyindoles in the serum to show on the chromatogram Indole chromatograms were also prepared from the urine of six healthy people who had been given DL-5-hydroxytryptophan intravenously during another investigation (Pare and Sandler, to be published) Apart from an absence of conjugates, these were strikingly similar to those obtained from our patient's urine

Quantitative excretion of 5-hydroxyindoles—Bladder specimens of urine recently obtained and submitted to quantitative partition of 5-hydroxyindoles gave the results shown in table I The 5-hydroxyindoleacetic acid excreted by this patient has been determined on numerous occasions and is fairly constant at 40–50 *mg* per g of creatinine or 40–60 *mg* per twenty-four hours The amount of 5-hydroxytryptamine excreted has been determined chemically on several occasions and agrees fairly closely with that originally determined pharmacologically (Snow et al 1955) If the sum of 5-hydroxytryptamine and 5-hydroxyindoleacetic acid is subtracted from the " total 5-hydroxyindoles ", the result is a function of the level of 5-hydroxytryptophan (Udenfriend et al 1957) and can be used as such for comparing different specimens

Ureteric specimens of urine from right and left ureters are compared in table II as regards partition of 5-hydroxyindoles

TABLE II—PARTITION OF 5-HYDROXYINDOLES IN URINE FROM URETERS

—	mg per g of creatinine	
	Lt ureter	Rt ureter
" 'Total 5-hydroxyindoles '	80 0	81 0
5-hydroxytryptamine	13 0	10 8
5-hydroxyindoleacetic acid	7 8	12 4
Balance = 5-hydroxytryptophan	59 2	57 8

Excretion of Histamine

From examination of an isolated specimen histamine excretion had previously been stated to be within normal limits (Snow et al 1955), but further estimations have repeatedly revealed a high output, 480–940 μg per twenty-four hours, the normal range being 18–62 μg (Roberts and Adam 1950)

Discussion

Enough cases of argentaffinoma syndrome have now been published for a fairly constant clinical picture to emerge which, broadly, varies directly in severity with the mass of tumour present It has been presumed, from the high level of 5-hydroxytryptamine found in the tumour, that this substance is liberated into the blood-stream Certainly the urinary 5-hydroxyindole pattern produced after the experimental injection of 5-hydroxytryptamine (Erspamer 1956) resembles that found in the argentaffinoma syndrome—i e, a large excess of the metabolite 5-hydroxyindoleacetic acid with only a small increase in 5-hydroxytryptamine

When our patient was first described (Snow et al 1955), a large urinary excretion of 5-hydroxytryptamine and a comparatively small one of 5-hydroxyindoleacetic acid were noted, together with other anomalies, for which at that time there was no obvious explanation Recently, however, Smith et al (1957), found in a patient with the carcinoid syndrome a large urinary excretion of 5-hydroxytryptamine and of 5-hydroxytryptophan, its precursor This aminoacid, derived from dietary tryptophan, had not previously been found in other than trace amounts, and it was postulated that renal metastases were secreting intermediary metabolites direct into the urine The intravenous pyelogram was considered to support this view, but Dick et al (1957), in a further report on the same patient, state that retrograde pyelography showed no abnormality

Since our patient also had a large urinary output of 5-hydroxytryptamine, urinary chromatography was carried out, whereupon large amounts of 5-hydroxytryptophan were found as well as 5-hydroxytryptamine and 5-hydroxyindoleacetic acid Intravenous pyelography did not reveal any obvious renal metastases in our patient, however, so ureteric catheterisation was done in an attempt to locate the fault, urine being collected from each ureter separately Indole partitioning gave similar results in both specimens, and, unless bilateral metastases of equal mass were present, which was unlikely, the explanation advanced by Smith et al (1957) cannot apply to our patient

Although Dick et al (1957) estimated the 5-hydroxyindoleacetic acid in ureteric specimens from their patient they took no account of possible differences in urine flow by relating the level of 5-hydroxyindoleacetic acid to that of creatinine The difference they found between the two specimens may therefore not be significant

Chromatograms of our patient's urine bore a striking resemblance to those obtained from urine passed after intravenous injection of 5-hydroxytryptophan into six normal subjects It therefore seemed likely that the principal metabolite of the tumour was 5-hydroxytryptophan, which, when released into the blood-stream, was decarboxylated to 5-hydroxytryptamine elsewhere 5-hydroxytryptophan-decarboxylase activity is known to be widespread (Gaddum and Giarman 1956), and since the level of 5-hydroxytryptophan decarboxylase is especially high in the kidneys (Clark et al 1954), the large output of 5-hydroxytryptamine could be due to direct decarboxylation there 5-Hydroxytryptophan which reached the kidney and escaped decarboxylation would pass unchanged into the urine, and the other major indole fraction, 5-hydroxyindoleacetic acid, would arise from 5-hydroxytryptophan decarboxylated at extrarenal sites and further

TABLE III—RELEVANT CLINICAL AND BIOCHEMICAL FEATURES OF THREE ATYPICAL CASES COMPARED AND CONTRASTED WITH "TYPICAL ARGENTAFFINOMA"

—	Present case	Case of Smith et al (1957)	Case of Waldenström et al (1956)	Typical argentaffinoma
Histology	Atypical, no argentaffin granules	Atypical, no argentaffin granules	Atypical, no argentafin granules	Characteristic argentaffin granules
Distribution of metastases	Mainly hepatic	Hepatic and osseous	Hepatic and osseous	Hepatic
Type of flushes	Bright-red histamine type'	Not discussed in detail	Bright-red histamine type'	Mixed cyanosis erythema, and pallor
Excretion of histamine	Great increase	Great increase	Great increase	Slight increase
Urinary 5-hydroxytryptophan (chromatographic)	Present	Present	Not stated	Absent
Urinary 5-hydroxytryptamine	Great increase	Great increase	Great increase	Slight increase
5-Hydroxytryptamine in tumour	Small amounts	High level	Not stated	High level

metabolised by monoamine oxidase The presence of relatively greater amounts of 5-hydroxytryptophan in the ureteric specimens is compatible with a sudden release of large quantities of it in response to an agent used for inducing or for maintaining general anæsthesia, during which striking and prolonged flushing was noted

It was originally reported that, although tumour tissue from our patient undoubtedly resembled that of a carcinoid tumour, no typical argentaffin granules were found (Prof A C P Campbell) Jacobson (1954) has emphasised the distinction, based on differential staining, between granular argentaffin cells (found in typical argentaffinomata) and argyrophil cells, which have no granules Dr Jacobson kindly examined material from our patient and reported that all the cells were argyrophil This finding fits in well with the site of the primary tumour in the stomach, where argyrophil cells are numerous but argentaffin cells less common

It is obviously tempting to suggest that argyrophil cells may form 5-hydroxytryptophan, whereas argentaffin cells, tumours of which are known to contain 5-hydroxytryptophan decarboxylase (Langemann 1956, Giarman et al 1957), form 5-hydroxytryptamine, but investigation of such a hypothesis will have to await the availability of more tumour tissue There is no inherent improbability, however, in the idea that each type of cell may have a different function, and that tumours may contain different proportions of each A precedent for a tumour with two distinct secretions has already been established in the phæochromocytoma, which may produce different amounts of noradrenaline and adrenaline This hypothesis may explain the high levels of 5-hydroxytryptamine in tumour tissue of the otherwise similar patient of Smith et al (1957), compared with the very low level of 5-hydroxytryptamine in tumour tissue of our patient

Another patient, having features in common with both our own and Smith's patient, was described by Waldenstrom et al (1956) Although the urinary indole chromatographic pattern was not described, higher levels of urinary 5-hydroxytryptamine were obtained by pharmacological assay than in any of the large number of patients with argentaffinoma investigated by these workers (Pernow and Waldenstrom 1957) Other atypical features suggesting the possible clinical identity of these three patients are shown in table III

Neither Smith et al (1957) nor Dick et al (1957) give a detailed clinical description of the flushing attacks in their patient, but the atypical bright-red persistent flush of ' geographical ' pattern reported by Waldenstrom et al (1956) and also seen in our patient, which could be attenuated by anti-histamine therapy, correlates well with the enormous output of urinary histamine in all three patients 5-Hydroxytryptamine is a mild histamine liberator (Feldberg and Smith 1953), so it is not surprising that several patients with the typical argentaffinoma syndrome had an increased output of histamine (Pernow and Waldenstrom 1957), but usually the levels attained are lower than those found in the three patients under discussion

It is improbable that the tumour produces histamine, and Waldenstrom et al (1956) did not detect any in biopsy material from their patient We found no direct histamine-releasing action of 5-hydroxytryptophan on intradermal injection in normal subjects (unpublished observation), but widespread peripheral production of 5-hydroxytryptamine resulting from the excess 5-hydroxytryptophan may have a more pronounced histamine-releasing effect than have the relatively small amounts of free plasma-5-hydroxytryptamine in the typical syndrome

We suggest that the anomalous findings in the three patients discussed can best be explained by the existence of a distinct clinical group of tumours producing 5-hydroxytryptophan

Summary

A patient with the carcinoid syndrome having many atypical features, including urinary excretion of 5-hydroxytryptophan, is described

It is suggested that this case and two others published, form a new clinical group of tumours which secrete 5-hydroxytryptophan

We wish to thank Dr H T Howat for permission to investigate this patient, Mr M Bell, of the clinical laboratory, Manchester Royal Infirmary, for some of the 5-hydroxyindole estimations, Miss Lilith Emslie for expert technical assistance, and the Royal Free Hospital Endowment Fund for defraying her salary, Dr D N Baron and Dr D A K Black for helpful criticism, and Prof K R Hill for providing facilities

INFLUENZAL ENCEPHALITIS

VICTOR DUBOWITZ
B Sc, M B Cape Town
SENIOR HOUSE-OFFICER,
QUEEN MARY'S HOSPITAL FOR CHILDREN, CARSHALTON, SURREY

ALTHOUGH cases of acute hæmorrhagic encephalitis were described as early as 1892 (Leichtenstern, Furbringer, Koenigsdorf) and were undoubtedly seen in the pandemics of influenza in 1890 and 1918, there have been few reports in recent years

Leigh (1946) described 2 cases of encephalitis during the influenza type-B epidemic of that year, Holmes (1947) recorded encephalitic symptoms following atypical pneumonia, and Jennings (1952) reported a case in which a patient with basal pneumonia and a rising type-A antibody titre developed neck stiffness and an abnormal cerebrospinal fluid (C S F)

Of 91 cases of encephalitis notified in England in 1951, 4 were listed as postinfluenzal (Conybeare 1952) Crome (1954) reported 3 adult cases of encephalitis occurring in Slough during the 1951 epidemic of influenza type-A Fernandez (1956) described a fulminating encephalitis in 7 infants, which he thought followed on influenza

During the current epidemic of influenza type-A (" Asian flu ") 2 children with an encephalitic illness were admitted to Queen Mary's Hospital for Children within three days of each other Both attend school in Caterham and had had recent contact with influenza at school and at home The clinical course was so similar that we believe that they had the same disease

Case-histories

Case 1.—A girl, aged 13, was admitted at 8 A M on Oct 17 After being at home with a severe cold for two weeks she had returned to school on Oct 15 Her nose was still blocked and she had a slight cough On the 16th she felt drowsy after coming home from school She was restless and moaned throughout the night At 6 A M she was found to be unrousable and incontinent of urine

On admission she was severely ill, unconscious, and very restless and irritable, with some degree of photophobia There was very little response to painful stimuli Her neck was slightly stiff and Kernig's sign was positive The right pupil was smaller than the left but the light reflexes (direct and consensual) were unimpaired The tone of the limbs was increased, with variable rigidity and athetoid movements of the arms (somewhat reminiscent of cerebral palsy) On the left side the biceps-jerk was absent, the knee-jerk increased, and the plantar response extensor

There were crepitations in both lung fields but no other pneumonic signs Temperature 97°F, pulse-rate 120 per min, respirations 25 per min and regular The C S F was clear and colourless, with 6 lymphocytes per c mm, and protein 50 mg and sugar 75 mg per 100 ml Globulin was not increased, and no organisms were found on staining or subsequent culture Blood-count 9000 white cells per c mm (neutrophils 78%, lymphocytes 17%, monocytes 5%) Blood-sugar and blood-electrolyte levels normal Urine contained acetone

She was given prophylactic penicillin, intravenous dextrose-saline solution, and paraldehyde to control the restlessness

On the evening of admission (Oct 17) her temperature was 102°F and her condition critical There was no change in the level of consciousness Both pupils showed repeated variation in size and in response to light

On Oct 18 she was still in coma but swallowed small quantities of fluid She was still incontinent of urine In addition, hyperventilation and mild tetany developed The C S F was again clear, with 10 lymphocytes per c mm and protein 35 mg and sugar 80 mg per 100 ml Direct smear and culture again negative

On Oct 19 her general condition was better and she seemed to improve for short spells when she would open her eyes and gaze about

On Oct 20 she made a dramatic recovery, spoke rationally, and took fluids and biscuits in the evening, though very sluggish The left leg was still hypertonic, with an extensor plantar response She was continent of urine The temperature was normal

By Oct 24 there were no abnormal signs in the nervous system, and she was allowed up in a chair

When discharged fully ambulant on Nov 2 she had no residual symptoms or abnormal signs

Complement-fixation tests for influenza-A antibodies gave a titre of 1 64 on Oct 21 and the same on Nov 1

Case 2—A boy, aged 10, was admitted on the afternoon of Oct 19 His illness had begun five days previously with a cough lasting two days, anorexia, and general malaise On Oct 17 vague abdominal pain developed, with bouts of vomiting which persisted About five hours before admission he became drowsy

On admission he was severely ill, unconscious, and restless He responded sluggishly to painful stimuli but did not obey commands There was no neck stiffness but Kernig's sign was positive Tendon-jerks were all present and brisk The plantar response was bilaterally extensor Muscle tone was normal Temperature 98°F, pulse-rate 110 per min

The C S F was clear and colourless, with no cells, protein 20 mg per 100 ml, and no increase in globulin No organisms were seen on the stained centrifugate and no growth resulted from subsequent culture

An intravenous infusion of dextrose-saline and Hartmann's solution was given into the right leg and restlessness was controlled with paraldehyde

On Oct 20 his condition was unchanged, though he could swallow small quantities of water His temperature did not exceed 99°F

On Oct 21 he made a dramatic recovery, returning to full consciousness within six hours The plantar response became flexor Lumbar puncture on Oct 22 produced a clear fluid containing no cells, 15 mg protein per 100 ml, and no increase in globulin No organisms were grown Blood-count 12,000 white cells per c mm (71% were neutrophils, 23% lymphocytes, and 6% monocytes)

When allowed up on Oct 25 he was found to have a foot-drop on the right side with gross weakness of the anterior crural and peroneal groups of muscles The distribution of the motor and sensory involvement was in keeping with a lesion of the lateral popliteal nerve There was no other evidence of focal involvement of the nervous system

Complement-fixation tests for influenza-A antibodies gave a titre of 1 4 on Oct 21 and 1 16 on Nov 2

Discussion

These two children had a severe encephalitis after a relatively minor illness Both passed into coma in less than twelve hours with extensor plantar responses and no significant abnormality in the cerebrospinal fluid In case 1 there was evidence of focal signs in the nervous system on the left side of the body, but in case 2 there were no localising signs After being gravely ill in coma (for three days in case 1 and thirty-six hours in case 2) both made a rapid recovery The residual lesion of the lateral popliteal nerve in case 2 is hard to account for except as due to trauma, but there was no direct evidence of trauma to the nerve by splintage or otherwise in the course of the intravenous infusion

The fourfold rise in titre in the complement-fixation test in case 2 indicates infection with influenza virus A The initial high titre in case 1 signifies a recent infection with influenza virus A (Stuart-Harris 1953)

The general course of the illness was very similar to that in children with influenzal pneumonia admitted during the present epidemic—namely, an acute illness lasting two or three days, with a fairly rapid onset and rapid recovery from the acute phase

Neither child has had recent vaccinations or any of the illnesses known to cause encephalitis The evidence favours a diagnosis of acute encephalitis due to influenza virus A rather than sporadic encephalitis happening to coincide with an outbreak of influenza (Stuart-Harris 1953)

I am grateful to Dr David Lawson for permission to report his cases, and to Dr G T Stewart (pathologist to the hospital) and the Public Health Laboratory, Colindale, for the complement-fixation tests

PERFORATION OF THE COMMON CAROTID ARTERY BY A FOREIGN BODY IN THE PHARYNX

M F Butler
M B Lond, F R C S
SENIOR SURGICAL REGISTRAR, WESTMINSTER HOSPITAL, LONDON, S W 1, AND KINGSTON HOSPITAL, SURREY

Massive hæmorrhage due to swallowed foreign bodies is most commonly caused by perforation of the aorta Barrie and Townrow (1946) collected 80 such cases Perforation of a major blood-vessel in the neck appears to be much rarer, and very few cases have been reported in recent years, but Schlemmer (1929) collected 29 cases up to that date, and in 17 of these a common carotid artery was involved

The following case is unusual, and has several interesting features, not the least of which is that the patient recovered, thanks largely to a fortuitous circumstance that made the foreign body easy to remove

Case-report

A married housewife, aged 51, was brought to hospital on Aug 12, 1956, about thirty minutes after a severe hæmorrhage from her throat She was in a collapsed state and her history was obtained partly from her husband and partly from herself when she had recovered somewhat About four weeks previously, while she was eating her dinner, a lump of meat stuck in her throat. She pushed it down with her fingers but felt pain in her throat Fearing that a fragment of bone might have become lodged she went to the casualty department of a local hospital and was reassured Dysphagia persisted but improved over the ensuing few weeks Suddenly, on the evening of admission, just after she had coughed, bright blood began to pour from her mouth, and shortly afterwards she fainted. The bleeding abated after an estimated loss of about two pints, and she was brought to hospital without delay She was admitted to a medical ward because the bleeding was at first thought to be a hæmatemesis or a hæmoptysis

She was pale and shocked, with temperature 97 F, pulse-rate 110, blood-pressure 100 40 mm Hg, and an ill-defined firm swelling deeply placed in the left side of her neck. Physical examination revealed no other abnormality Chest radiography showed normal lung fields

Treatment and Progress—Her general condition improved steadily with anti-shock treatment, including blood-transfusion, but during the ensuing twelve hours she regurgitated small amounts of altered blood at short intervals The swelling in her neck appeared to diminish during this period The amount of hæmoglobin in her blood eight hours after admission, by which time she had received two pints of blood, was only 48% By this time it was clear that the hæmorrhage had come from a lesion in her pharynx or upper œsophagus, and a surgical opinion was sought I first saw the patient fourteen hours after admission, and at this time, though pale, her general condition was satisfactory The only abnormality was an elongated pulsatile swelling some 3 in × 1 in in the position of the upper part of the left common carotid artery

Direct Pharyngoscopy and Œsophagoscopy—Under general anæsthesia the pharynx was first inspected with a long laryngoscope A thread-like structure lying against the posterior wall of the hypopharynx was grasped with forceps and pulled out It proved to be a length of thread, and with it came a somewhat corroded sewing-needle 1¼ in long, which had providentially remained threaded After this there was no further hæmorrhage

Postoperatively penicillin was administered for five days, and the patient made an uneventful recovery The swelling in her neck disappeared within a week

The patient recalled that, about a month previously, she had served a meal after she had been sewing She thought that she must have put her needle into the front of her dress and that it must have dropped into the meat as she bent over to serve it

Discussion

The diagnosis was not so straightforward as might be supposed, partly because the patient was unaware that she had swallowed the needle, and partly because she was too ill after the hæmorrhage to emphasise the amount of dysphagia she had had during the previous month Chest radiography showed no abnormality in her lung fields, but reinspection of the film subsequently showed the needle clearly at the extreme upper end of the radiograph When the wet plates were examined originally this part of the radiograph had been obscured by the frame carrying the film The swelling in the neck was evidently a hæmatoma caused by bleeding into the tissues of the neck at the time of the original hæmorrhage The regurgitation of altered blood during the twelve hours after admission was associated with considerable diminution of the hæmatoma, suggesting that it was discharging into the pharynx

Perforation of a major artery usually follows the swallowing of a foreign body only after an interval of several days In this case the interval was a month Schlemmer (1929) explained this latent period by pointing out that a foreign body would not readily enter a mobile structure such as a large blood-vessel until that structure had become fixed by inflammation in its neighbourhood and, perhaps, softened by the same process Continued pressure would then lead to gradual erosion of the vessel wall

These was no evidence of sepsis in the present case, but it is certainly a factor of importance in some cases, such as that in which a foreign-body perforation of the wall of the right pyriform fossa had caused a parapharyngeal abscess (Thomson and Negus 1949) This had led to sloughing of the wall of the common carotid artery with fatal hæmorrhage It is, however, quite possible for a sharp foreign body rapidly to penetrate the wall of the gullet and of a neighbouring vessel Sneller (1936) described a woman who had sudden pain in the neck while eating chicken and rapidly developed a cervical hæmatoma An impacted bone was seen on endoscopy but could not be removed, because blood obscured the field of vision

Fatal hæmorrhage due to perforation of the œsophagus by foreign bodies is commonly preceded by a smaller warning hæmorrhage If the possibility of a foreign body were considered in every case of bleeding from the pharynx or the œsophagus or of unexplained hæmatemesis, mistakes would be avoided, and timely operation might well save life

Summary

Severe hæmorrhage followed perforation of the common carotid artery by a needle swallowed a month before Removal of the needle was followed by an uneventful recovery

I wish to thank Dr J W Joule, under whose care this patient was admitted, for permission to publish this report

Preliminary Communication

TECHNIQUE OF HUMAN BONE-MARROW TRANSPLANTS

THE successful transplantation of bone-marrow in mice[1] and rabbits[2] after whole-body X-irradiation has revived hopes that bone-marrow could be satisfactorily transplanted in man[3] The potential danger of whole-body irradiation, which is a hazard for all workers in nuclear irradiation, indicates the need to explore this possibility We have attempted marrow transplantation in five cases and feel that the results may be of interest

The Recipients

Four of the patients had advanced malignant disease and anæmia, with leucopenia or thrombocytopenia indicating grave damage to the marrow, confirmed by marrow examination This precluded further radiotherapy The fifth patient had aplastic anæmia after being successfully treated for carcinoma of the vocal cord a year previously

The Marrow Suspensions

Donor marrow was obtained by multiple puncture of iliac crests of relations who had the same ABO and rhesus blood-groups as the patient and whose red cells were compatible with his serum Four parts of the marrow aspirated were added to one part of sterile acid-citrate dextrose solution, and these suspensions were injected into the recipient as soon as possible after collection

Administration

In three cases the suspension was introduced into the descending aorta, by catheterising the femoral artery (two cases) or the left radial artery (one case) In the fourth case it was introduced by percutaneous puncture of the abdominal aorta In the fifth the suspension was injected intravenously The reason for choosing the aortic route in cases 1, 3, 4, and 5 was that the pelvis and lumbar vertebræ had been deliberately irradiated in the previous fortnight to destroy the cells present and produce hyperæmia, thus providing a suitable site for the injected marrow

The amounts of marrow obtained and injected were

Case no	Age (yr)	Sex	Weight (kg)	No of donors	Volume injected (ml)	No of cells injected	No of cells per g body-weight (× 10⁴)
1	25	F	50	3	43	$1\,019 \times 10^{9}$	2 04
2	11	M	50	1	25	$0\,575 \times 10^{9}$	0 115
3	14	F	30	3	44	$1\,188 \times 10^{9}$	3 96

All the patients received prednisone 30 mg daily both before and after the infusion of marrow

Results

Case 1—A woman, aged 25, with advanced Hodgkin's disease On Nov 5, 1956, 43 ml of suspension was injected from a catheter into the aorta at the level of the 8th dorsal vertebral body This produced no symptoms No improvement followed No evidence of the injected cells was found at necropsy 3 days later

Case 2—A boy, aged 11, with aplastic acute leukæmia and staphylococcal septicæmia On Dec 14, 1956, 25 ml was injected intravenously No untoward symptoms No improvement noted At necropsy 10 days later there was no conclusive evidence of injected marrow

Case 3—A girl, aged 14, with neuroblastoma with multiple deposits in skeleton and soft-tissues On June 19, 1957, 44 ml of suspension was injected by percutaneous aortic puncture Patient died from retroperitoneal hæmorrhage after completion of this operation

Case 4—A woman, aged 66, with advanced lymphatic leukæmia had her pelvis irradiated to a skin dose of 2500r Puncture of an iliac crest immediately before infusion showed no nucleated red blood-cells On Aug 13, 1957, 47 ml of suspension was injected by catheterisation of a femoral artery at the level of L2 The patient tolerated this well and showed considerable clinical improvement A month later nucleated red cells were readily seen in the iliac-crest marrow obtained by puncture This patient is still alive, and the procedure appeared to improve her general condition very greatly This patient is still alive (Jan 9, 1958) and is in fair general health Her leukæmic condition is unchanged

Case 5—A man, aged 67, with aplastic anæmia had been successfully irradiated for carcinoma of the larynx His pelvis and upper femora were irradiated to a dose of 2800r (skin dose) This was followed by 15 mg of nitrogen mustard ('HN2') as a single injection 48 hours before the infusion of marrow This was to depress further the reticuloendothelial system On Oct 10, 1957, 48 ml of suspension was injected by catheterisation of a femoral artery This man feels better for the procedure The white-cell count, which previously was 500 per c mm, is now 1000–1500 per c mm A comparison of sternal and iliac marrow taken at the same time a month later shows more nucleated red cells (18 8%) in the iliac-crest specimen than in the sternum (9 2%) This patient died of bronchopneumonia on Dec 9, 1957

These results show that it is technically possible to inject marrow cells in man It would be desirable to increase the amount injected In this connection the use of marrow from ribs surgically excised for non-malignant conditions is being explored In the two examples we have studied, suspensions containing more than $1\,5 \times 10^{9}$ cells were readily obtained from each rib

In conclusion we wish to emphasise that this is purely preliminary work

We are grateful to Sir Stanford Cade Mr E Stanley Lee, and Dr C J Gavey for permission and encouragement to treat their cases, and to Dr B Strickland, of the radiodiagnostic department, for his invaluable assistance

Growth of Viruses

AT a meeting of the section of pathology on Dec 11, Prof H B MAITLAND said that the mechanism of reproduction of bacteriophage had been taken as a prototype of virus reproduction in general The desoxyribonucleic acid (D N A) of the phage alone entered the bacterial cell and determined the synthesis of phage D N A and protein, which were organised at a later stage into morphologically mature phage particles These particles were released by bursting of the bacterium During the earlier part of the process of reproduction no infective phage was found in the cell, and this period had been referred to as an "eclipse phase"

The ribonucleic acid (R N A) of tobacco-mosaic-disease virus played a similar role in the reproduction of this virus (T M V) It determined the infective property of the virus and the nature of the lesions produced The R N A of one strain had been combined in vitro with the protein of another to make a hybrid strain of T M V virus Plants infected with such hybrid strains had symptoms characteristic of the strain, providing the R N.A and the new virus produced as a result of infection corresponded in every respect with the R N.A -donor strain, R N A could be extracted from T M V -diseased plant material and was itself infective, causing characteristic symptoms and the production of new complete virus

An alternative method of reproduction was by binary fission, as in bacteria and in certain rickettsiæ The reproduction of animal viruses might be by binary fission, or it might be similar to bacteriophage with an eclipse phase as part of the process, but some intermediate form of reproduction might exist

The psittacosis virus and other closely related viruses multiplied by developing large forms which increased in number by binary fission and later subdivided into the smaller bodies which were the naturally infective virus Because of their method of division psittacosis and similar viruses were regarded as resembling the rickettsiæ rather than the viruses

The vaccinia virus representing the "pox" group of viruses was next to the psittacosis group, and morphological studies of ultra-thin sections of infected tissue had not suggested reproduction by binary fission Growth curves of vaccinia in the chorioallantoic membrane of the developing chick embryo, as well as in a number of systems of tissue and cells incubated in nutrient media in vitro, had been studied, but further work was required to elucidate the mechanism of growth of vaccinia virus

Nucleic acid, which was itself capable of transferring infection to susceptible animals, could apparently be separated from tissue infected with meningoencephalitis virus and with eastern equine encephalomyelitis virus, and this seemed to bring these two animal viruses into line with bacteriophage and tobacco mosaic virus with regard to the role of nucleic acid in virus reproduction

Reviews of Books

Rheumatoid Arthritis

CHARLES L SHORT, M.D, WALTER BAUER, M.D, WILLIAM E REYNOLDS, M.D Cambridge, Massachusetts Harvard University Press London Oxford University Press 1957 Pp 480 55s

THIS book is based on a study of 293 patients with rheumatoid arthritis at the Massachusetts General Hospital, who have been followed for at least twenty years Findings were recorded on a predetermined plan and according to presenting symptoms and signs (which are compared with those of a non-rheumatoid control series) The patients' subsequent histories are analysed in great detail

Tracing the evolution of the concept of rheumatoid arthritis, Dr Short and his colleagues show that most previous students of arthritis have failed to distinguish degenerative from rheumatoid joint disease in published series of patients The authors set out their own criteria for diagnosis, and while they have undoubtedly avoided previous pitfalls, it is a weakness of their otherwise excellent analysis that they have included under the heading of rheumatoid arthritis 44 patients with spondylitis, as well as 10 with psoriasis and arthritis and 3 with ulcerative colitis and arthritis Most opinions (supported by the recent evidence of the specific agglutination tests for rheumatoid arthritis) would nowadays distinguish these conditions as separate diseases Nevertheless this book is one of the most authoritative and comprehensive studies of rheumatoid arthritis yet published It is in the highest tradition of medical scholarship and will remain a standard work of reference for many years

Deafness, Mutism and Mental Deficiency in Children

LOUIS MINSKI, M.D, F R C P, D P.M, consultant psychiatrist, Royal National Throat, Nose and Ear Hospital, London. London Heinemann Medical Books 1957 Pp 82 12s 6d

THE difficulty of distinguishing between deafness and mental deficiency has only lately been appreciated Many children whose disturbed behaviour had been attributed to mental deficiency have been discovered to be deaf and within the normal range of intelligence The child who is both partially deaf and mentally retarded is particularly hard to assess For the past five years Dr Minski has been able to study such problems in the research unit for children at Belmont Hospital, and this small book summarises his experience and opinions

He discusses the general aspects of the subject and gives the relevant clinical data, before describing the layout and staffing of the Belmont unit and the methods of assessment Short notes follow on audiometry, electrophysiological methods of assessment and psychological testing by the Dreyer-Collins and Merrill-Palmer tests Although Dr Minski is to be congratulated on drawing attention to the problem of the deaf who have been erroneously diagnosed as defective, he has by implication been of less service to the mental defective who is not deaf Unfortunately in the first sentence of the first chapter he quotes the definition of the "feebleminded" child from the original Mental Deficiency Act of 1913, without reference to the amendments effected by the Education Act of 1944 relating to the "educationally subnormal" child It is also disappointing to those who are trying to improve the training of mentally defective children for a note on the dust cover to refer to such children as those "for whom nothing can be done"

It is to be hoped that Dr Minski will, in a second edition, amplify his theme by a more detailed exposition of clinical matters relating to deafness and also put into better perspective the problem of the mentally defective child, especially since the publisher has abbreviated the title on the cover to Mental Deficiency in Children

An Introduction to Functional Anatomy

DAVID SINCLAIR, M.D, professor of anatomy, University of Western Australia Oxford Blackwell Scientific Publications 1957 Pp 426 42s

WHILE teaching at Oxford, Professor Sinclair lectured for some years at the Dorset House School of Occupational Therapy, and his new text is closely linked to the syllabus for occupational therapists, and for those with similar needs, such as physiotherapists As is customary in such circumstances, anatomy and physiology are combined

Like all who attempt simultaneous description of structure and function, Professor Sinclair meets difficulties But though his book may appear at first sight to be divided into a first part largely dealing with function, and a final section actually entitled Topographic Anatomy, careful reading will show that in fact *anatomy and physiology* are far more closely interwoven than is apparent from the table of contents

This bold attempt is on the whole successful It is a pity though that the integration of the autonomic with the rest of the nervous system is not brought out more clearly Some readers may wonder too whether the orthodox insistence on a primary protective function in the ribs is not medical rather than biological The distinction is not made between primary cartilaginous joints and sutures, as growth mechanisms, and the true locomotor joints of the body These are small criticisms, but in a book which in title puts the accent on function, such matters should be given more clarity than is usual in strictly anatomical texts

The book ends with an excellent glossary and even a small bibliography Illustrations are simple but adequate In all it is a most readable work, which deserves and can be recommended to a far wider circle of readers than the one to which it was immediately directed.

Suburban Neurosis Up to Date

It is now nearly twenty years since Taylor[1] described in our columns a condition which he called "suburban neurosis" He was writing about life in the new housing estates which had sprung up round our great cities In these estates—sometimes jerry-built and almost always devoid of social amenities—it was considered correct to keep oneself to oneself The one-child family and the baby car represented the height of ambition, and, though physical health was comparatively good, many of the people had anxiety states, often with hysterical features and reactive depression, which Taylor attributed to boredom, loneliness, and a false set of values One of the happier results of the 1939–45 war, and particularly the continuing threat of air-raids, was to build a new community life in such places Fire-watching, the Women's Voluntary Services, evacuation, and many forms of mutual help broke down the previous social isolation, and the prevalence of neurotic illness declined spectacularly Afterwards there was some slipping back, but the social isolation of the inter-war years has not been fully restored

Since the war, the emphasis of building development has changed Green belts of a sort have been established around the cities, and instead of the speculative hire-purchase estates we have had huge blocks of municipal flats, large out-county municipal estates, and the new towns (Only within the past three years has speculative building recommenced, and its scale is much smaller than before) Though redevelopment in municipal flats has had its social difficulties, old ties of friendship and kinship have not been broken, as must happen when a family moves right out of the city In the new towns, industry and homes have moved out together, and imaginative social provision has done much to reduce the risk of neurotic reactions in a new environment—though the combination of high rents, hire-purchase payments for furniture, and rapidly increasing families often leads to justifiable financial anxiety[2] The out-county municipal estates, however, have long been suspected of partly repeating the story of the pre-war speculative estates Great working-class populations were translated to new homes in country suburbs, and, though the standards of housing were admirable, social provision was at first very meagre the great majority of the wage-earners continued to earn their living in London, while the women tended to follow the obsolescent middle-class pattern of social isolation as a standard of respectability Hence it was good that a team from what was then Prof J M Mackintosh's department at the London School of Hygiene should decide to make a detailed study of what was going on in one of these out-county estates to the north of London Two reports of this team's work appeared last year,[3] [4] and a third, by Martin, Brotherston, and Chave,[5] deals with the incidence of neurotic and psychotic illness

Four sources of information were tapped—mental-hospital admissions, referrals to psychiatric outpatient clinics, general-practitioner consultations, and the results of a direct-interview survey Between 1949 and 1954, there were 129 admissions to mental hospitals from the estate, giving a rate slightly more than 50% above what would be expected from national figures Admissions for neuroses were twice the national rate, with neurotic reactive depression among females predominating On the other hand, the discharge-rate was high, and the average period in hospital short Psychiatric outpatient referrals did not differ markedly from the national average, but were twice as numerous as in neighbouring areas served by the same hospitals During 1953, all the doctors in general practice on the estate maintained records of all their consultations, and the following table shows the number of patients consulting them for various complaints (per 1000 registered population) set alongside "expected" figures

Diagnosis	*Actual estate figure*	*Expected estate figure on national basis*
Psychosis	3 0	1 0
Anxiety neurosis	23 4	11 8
Disturbances of sleep	25 6	6 3
Anorexia	9 7	2 1
Palpitations	1 1	0 2
Debility and undue fatigue	50 9	13 3
"Depressed" or depression	7 0	3 3
Headache	29 6	10 0
Urticaria and allergic rash	24 8	19 5
Duodenal ulcer	10 2	3 9
Asthma	12 1	7 6

The direct-interview survey showed that the self-estimate of "nerves" on the estate was 223 per 1000 adults, compared with the national figure of 126 obtained by the Social Survey of Sickness[6] Complaints of neurotic symptoms were higher among those who had lived on the estate for two years or less than among those who had been there for three to six years, but even the oldest inhabitants had rates far above the national figures Admittedly, rehousing on an out-county estate is partly determined by medical certificate, but a psychiatric or quasipsychiatric diagnosis had been submitted for only 2% of men and 8% of women, and these can account for only a small part of the excess of neurotic illness encountered

Here, then, is the suburban neurosis presenting itself again, and probably for much the same reasons As Professor Brotherston and his colleagues remark, each family "keeping itself to itself" generates a degree of loneliness and social isolation inconsistent with good mental health The findings at direct interview and the statistics for juvenile delinquency suggest that, with time, there is a slow improvement, but the picture remains a sad one Physical planning on the out-county estates appears to be out of step with social planning, and rehousing has improved physical environment at the cost of mental wellbeing There is reason to think that in the new towns the lessons of the past have been learnt and applied Precise statistical evidence has yet to be collected, but we agree that "comparable studies of mental health problems in New Towns would be especially illuminating" The present study supports the view that social environment affects the prevalence not only of neurotic but also of psychotic illness, and, if this is so, the future of preventive psychiatry will lie as much in social planning as in early diagnosis and treatment A few thousands of pounds spent on social amenities and social development may save hundreds of thousands used on therapeutic services or wasted in labour lost

Artificial Insemination

ARTIFICIAL insemination of livestock is now widely practised, and its techniques are both simple and reliable There are few practical difficulties in carrying out the same process in human beings, and most of what has been written on this subject turns on the desirability of doing so In a new review[1] of the human applications of the method, a Dutch obstetrician and gynæcologist deals with both types of insemination now in use—from the husband and from a donor or donors He discusses techniques, but he is more closely concerned with far more contentious matters Few biological discoveries trespass on so many sensitive areas of human belief, and the body of resulting comment—legal, religious, and ethical—is the main topic of Dr SCHELLEN's review For some commentators every stage of the process, from the manner of collecting semen and the desirability of paying the donor to the risk of inadvertent marriage between siblings, is of immediate and serious moral importance Others are more preoccupied with the effects on parents, child, and doctor of granting or refusing a request for donor insemination In the discussion of these possible effects, rationalisation often plays a recognisable part SCHELLEN does not wholly escape the charge of special pleading in his chairmanship of the debate, and his *parti pris*, although evident, is overtly declared only in his last few pages But his book is a fascinating study of the social anthropology of human opinion

Such an alarming battery of theological, moral, magical, psychological, and admonitory comment is likely, thus presented, to deter any cautious doctor from involving himself, at least in donor insemination, and the deterrent action was perhaps SCHELLEN's aim Many whose ethics are based on similar religious belief may well agree with his assessment and emphasis To others, it may seem that patients seeking medical help in their desire for children are less agitated by scruple over details of procedure than are their spiritual mentors At the same time, the possibility of all kinds of trouble arising from donor insemination must be evident to all but the blindly sanguine SCHELLEN quotes many such forebodings, the actual failures he mentions are largely anecdotal But his book poses once more one of the central questions of medical ethics—how the moral and religious opinions of the doctor and his patient should determine the advice given in matters of conduct He offers only conjecture on the motives which lead patients to request donor insemination These are important and probably diverse it would be possible to take the extreme position that well-adjusted patients will not require donor insemination, and the ill-adjusted may be harmed by it, such a view leads, at least, to dignified inactivity Some doctors believe that donor insemination has a valid place in medical practice, and meets both a demand and a right There are those who would no doubt agree with GUTTMACHER,[2] both in his summary handling of the theologians and in his general advice—that the doctor should act on his judgment and knowledge of the patient, with privacy and without formality of any kind, avoiding the formidable legal instruments prepared by some authorities bent on self-protection, refusing high fees, and "putting the name of the husband as father on the appropriate forms—a white lie here is a humane, friendly deed" At the opposite extreme, there is anxious debate whether a donor who accepts payment is morally fit for fatherhood, or whether he is entitled to demand it for "a service more distasteful than that of a blood donor" Even the use of the husband's semen gives rise to heart-searching in some places Every approach, from an ingenuity of scruple worthy of *Hudibras* to frank commercialism, is cited in SCHELLEN's collection the only criticism of its scope is that this citation of extremes leads to an under-representation of more moderate judgments

Since many critics of artificial insemination base their objection, at least in part, on genetic and psychological risks, it is unfortunate that we have here no follow-up studies of couples who have borne a child in this way, and no serious discussion of the biological implications in terms of modern genetics Evidence of this kind might form a more manageable basis for advice than appeals to general, or even infallible, moralities The genetic comment is uncritical, both in exaggerating by implication the physical consequences of accidental endogamy, and in accepting anecdote—about supposed man-ape hybridisation, for example There are those who will read Dr SCHELLEN with irritation, but the human anxieties he writes of are real and deepseated, even when unspoken Mountains of this kind have to be scaled by the patient, even when they have been made from what, to the unconvinced sceptic, appear to be ethical molehills Some of the instances of medical insensitivity to which SCHELLEN refers are warnings against overconfidence and undue persuasion

Eradication of Malaria

MALARIA eradication, though known to be feasible, might have been pursued only exceptionally but for the fear that, owing to the growth of anopheline resistance, control by means of residual insecticides could not be maintained permanently The W H O Expert Committee on Malaria, in recommending eradication,[3] points to its social and economic advantages, and remarks that it needs special finance for a limited time only Moreover, in achieving eradication a government gains an asset in well-trained staff available for other services

Annotations

INFLUENCE OF ACID-BASE BALANCE ON THE ACTION OF DRUGS

CHANGES in acid-base balance have long been known to influence both the therapeutic and toxic effects of salicylates Administration of sodium bicarbonate reduces the toxicity and plasma level of salicylate[1], and Smith et al[2] showed that this was due to increased rate of excretion of salicylate in alkaline urine The clearance of unconjugated salicylate is much lower than that of inulin in acid urine, but is higher in alkaline urine[3] Hyperventilation and acetazolamide, both of which produce an alkaline urine, are as effective as sodium bicarbonate in increasing salicylate excretion[4] Since acetazolamide produces systemic acidosis,[5] the increased salicylate excretion in alkaline urine must be directly related to the urinary pH and not to change in systemic acid-base balance

More recently the excretion of two other important drugs, phenobarbitone and mecamylamine ('Inversine'), has been shown to resemble that of salicylate Phenobarbitone, which is a weak acid, is excreted more rapidly when the urine is alkaline[6] Barbitone itself, although also largely eliminated in the urine, is little affected by variation in acid-base balance Mecamylamine, a weak base, is excreted more rapidly when the urine is acid[7–9] Other ganglion-blocking drugs, such as hexamethonium and pentolinium, are much stronger bases and are unaffected by acidosis or alkalosis Many other weak bases, including mepacrine and chloroquine,[10] [11] procaine,[12] and quinine,[11] [13] are excreted in the same way as mecamylamine Variation in excretion-rate in the case of the weak-base drugs is, however, of little importance since only a small proportion of any dose appears in the urine Alkalinisation of the urine increases the hypotensive effect of mecamylamine,[8] [9] and reduces the toxicity of phenobarbitone and salicylate Acidification of the urine by ingestion of ammonium chloride has the opposite effect Treatment with sodium bicarbonate has been recommended both in salicylate[4] and in phenobarbitone[6] poisoning Other workers have recommended dialysis with the artificial kidney in salicylate[14] and barbiturate[15] intoxication Probably the ideal method of removing the drugs from the body in severe poisoning is a combination of the two methods

Variation in the rate of excretion of these drugs influences the amount retained in the body, and therefore there is a gradual modification of their pharmacological effects In contrast, sudden changes in systemic acid-base balance may rapidly alter the distribution of drugs within the body, while the total amount remains unchanged This may be associated with corresponding change in their specific action Respiratory acidosis induced by breathing 10% CO_2 increases the plasma levels of the bases mepacrine and chloroquine[16] and of mecamylamine,[17] but reduces those of the acids phenobarbitone[6] and thiopentone[18] Except in the case of thiopentone, this is associated with a reverse change in the intracellular concentration of the drugs Thiopentone is largely stored in adipose tissue, and in this case acidosis causes mobilisation of the drug from body fat[18] An increased plasma level caused by acid-base change increases the pharmacological effect of mecamylamine,[17] but reduces that of phenobarbitone[6] This observation may be of considerable practical importance during anæsthesia

VIRAL HEPATITIS

VIRAL hepatitis remains common, and, though mortality rarely exceeds 0 2–0 5%, the illness may be long and unpleasant and permanent hepatic damage the final result Large epidemics are fortunately rare, but under conditions of war or civilian catastrophe big outbreaks have been common during the past two centuries The disease has been intensely studied in recent years, and it was the subject of a symposium at the last annual meeting of the American Medical Association Advances in treatment have unfortunately been trivial, but some progress in the understanding of ætiology and epidemiology has been achieved and was well reviewed at the symposium by Havens[19]

The two varieties of the disease are distinguished mainly by the route of infection and the incubation period The causal agent of the naturally acquired disease (infective hepatitis) can be demonstrated during the period of infectivity in the blood-stream as well as in nasopharyngeal washings and in the fæces The second variety of the disease has been given the name "homologous-serum jaundice" and the causal agent has been found only in the blood of patients and never in the pharynx or fæces This second variety is transmitted only as a result of artificial procedures—e g , blood-transfusions or injections given with an imperfectly sterilised syringe Transmission of infective hepatitis, on the other hand, is usually by close personal contact or by fæcal contamination of food or water, but, since the virus is also present in the blood-stream at least for some days or weeks, it can also be transmitted in the same way as homologous-serum jaundice

The viruses responsible for these two diseases belong to the class of filter-passers, and they are both remarkably resistant to chemical and physical methods of sterilisation The relationship between them remains an intriguing problem The coincidence between outbreaks of hepatitis among patients attending venereal-disease clinics for arsenical therapy and the presence of an epidemic of infective hepatitis in the same locality suggested a close connection between the viruses[20] But the fairly consistent and striking difference between the incubation periods of the two forms of the disease and the difference in the distribution of viruses in the infected person rules out the possibility that the viruses are identical This conclusion is firmly supported, moreover, by two further pieces of evidence Firstly, the agent of infective hepatitis confers a strong and lasting immunity against reinfection by infective hepatitis, without apparently enhancing the resistance to the serum jaundice Secondly, an injection of normal adult human gamma-globulin gives considerable protection against infective hepatitis but is without demonstrable effect against the other form of the disease Nor can these differences be entirely attributable to the different routes of infection, since parenteral transmission of infective hepatitis results in a disease with the characteristic short incubation period and the appearance of the virus in the throat and fæces The conclusion, therefore, that virus hepatitis may result from infection by either of two immunologically distinct agents seems well founded Their usual mode of transmission is equally distinct and well established, and the prophylactic measures are plain All that is required, therefore, to reduce the incidence of this disease is their widespread and meticulous application As Dr Morton remarks in a letter on p 164, efficient syringe sterilisation and a scrupulous injection technique are more than ever important at present, when large programmes of prophylactic inoculation are about to be carried out

FAILURE TO GAIN WEIGHT IN INFANCY

IN a recent symposium on the relationship between pædiatric disorders and nutrition, Holt[1] discusses excessive loss of nitrogen from the body as a cause of failure to thrive in infancy Cystic fibrosis of the pancreas is one condition in which there is abnormal fæcal loss of nitrogen, and in malignant malnutrition, or kwashiorkor, this fæcal loss is augmented by losses through the kidney It seems likely that in kwashiorkor both digestive and tissue enzymes are deficient, so that much of what little nitrogen is absorbed cannot be used and escapes in the urine Holt also draws attention to the need for caution in the treatment of patients with protein starvation High levels of non-protein nitrogen have been found in the blood of patients with kwashiorkor who were taking protein by mouth,[2] and toxic effects have followed intravenous feeding with hydrolysed protein or amino-acids

Careful investigation of most cases of "marasmus" will often reveal some obvious cause such as a congenital abnormality of the alimentary tract, heart, or nervous system, or perhaps an unsuspected infection On the other hand, much elaborate effort may be needed to uncover certain metabolic anomalies The symposium gives up-to-date information about such disorders as infantile renal acidosis, idiopathic hypercalcæmia, and galactosæmia, and refers to the various types of aminoaciduria In these and allied disorders, the metabolic anomaly may exert its effect largely through impairment of appetite, and calorie losses in the excreta are unlikely to be large unless there is an accompanying glycosuria

Holt also refers to a further group of children in whom there is a discrepancy between the amount of food the child is thought to be taking and the amount he actually receives The difference may be the result of inaccurate or careless preparation of feeds, rumination or unreported vomiting, or, on occasion, downright deceit Such children are often said to be suffering from "mismanagement" or "psychological upset", and a spell under close observation in nursery or hospital may disclose a steady weight gain even though the food intake is apparently no different from that given at home

PRESSURE GROUPS

TODAY the words "pressure group" often drop off the journalist's pen or the orator's tongue, and to most readers and listeners they suggest yet another disagreeable development of the modern world But this reaction is often unreasonable, for it is the name rather than the device that is novel Runnymede, for instance, was the scene of one effective pressure group, and such reforms as the abolition of slavery, the Factory Acts, and (in more modern times) equal pay for women were all initiated by small groups of people, who, by exerting pressure, gradually brought the Government and the public round to their way of thinking Nevertheless, though they can thus claim respectable ancestry and good service in the past, pressure groups, like other useful institutions, are changing with the changing times, and their new name is perhaps a sign of the community's uneasy recognition of their growing importance and power The part they are now playing in the political life of the nation is examined with discernment and tolerance in the current issue of the *Political Quarterly*,[1] where the social scientist as well as the politician will find much of interest

As the machinery of government has changed, so have the methods of the pressure group The Runnymede group was small, and its methods direct and swift, but in a parliamentary democracy they would be less effective New means of communication and ease of transport have given the modern pressure group new opportunities, but literacy and universal suffrage mean that it must convince more people if the climate of opinion is to be altered The multiplication of pressure groups has in part been fostered by the Government's pervasion of the life of the citizen To the courts of justice, the Army, and the Navy, for which the State has long been responsible, have been added such diverse enterprises as schools, roads, hospitals, pensions, mines, postal services, and museums, and each addition has provided a focus (or indeed foci) for several pressure groups The Association of the ex-Bowmen of Agincourt, for instance, may have met annually on St Crispin's day, but, unlike the ex-Service associations of our own time, it probably did not press the pension claims of its members

Among these new groups the most conspicuous are the innumerable vocational ones formed by workers, whether members of a profession, traders, or artisans, and Sir Winston Churchill, with his historian's outlook, has perceptively described the trade unions as "an estate of the realm" While some of these are profoundly concerned with the public interest, others are concerned mainly or entirely with the interest of their members

Besides these, however, there are still the groups whose sole purpose is to work for a cause—the legalisation of abortion or the abolition of capital punishment, to take two topical examples True to their traditional pattern, most of these groups are small, with meagre funds, but their influence cannot be measured by their size or their finances, and it is largely through the kind of enlightened and disinterested pressure they exercise that so many wrongs have been righted by persuasion and that British history records so few revolutions Unfortunately today the small ill-financed pressure group may be somewhat at a disadvantage, for publicity has become a more expensive commodity to reach the public's ear and eye usually costs money, while competition for the public's mind and interest is keen It is indeed perhaps a sign of this competition that the Government are themselves beginning to use some of these groups as a means of exerting pressure on the public The subsidies which they offer to bodies such as the Marriage Guidance Council and the National Association for Mental Health are too modest to sap independence, but here is a development which may well initiate yet another morphological type of pressure group

[2] Dean, R. F A., Schwartz R. *Courrier*, 1954, 4, 293

[1] *Political Quarterly*, January-March, 1958

In many ways the growth of pressure groups, in number and influence, is a healthy sign the device is one which can be used, with typical British economy, either as a spur or a bridle for the Government of the day But with the shifting emphasis of these groups, their growing power, and the preoccupation of so many of them with the rights of limited sections of the community rather than the propagation of ideas and principles, it is essential that the rights of those who are prevented from forming groups, whether by isolation, ill health, youth, or age, shall not be neglected The best of our pressure groups have always been created for the protection of the weak, and, despite all the changes time brings, their true strength will probably always lie in their readiness to recognise where help is most needed

ATOMS, BRONCHITIS, AND CLEAN AIR

THE Windscale accident drew public attention to the risks of the civil use of nuclear power, but these risks are at least foreseen, as the report of the Fleck Committee (summarised on p 157) illustrates To quote the medical officer of health for Wigan,[1] " if the approach to the first industrial revolution had been as carefully and painstakingly controlled as regards the possibilities of environmental hazards to mankind as is the approaching Atomic Age we should now be a much healthier nation "

Nuclear power may in due course help to remedy some defects by freeing us from the need to burn coal in great quantity and so lessening the damage, to ourselves and our buildings, that comes from air pollution We may hope that, before very long, smoky grimy industrial towns, and their coughing citizens, will be as distant memories as the London cholera epidemics are now

Some measure of the havoc caused by the wastes poured into the atmosphere in industrial towns is given in a recent review of bronchitis in Salford [2] In the years 1946–55 the death-rate from bronchitis per 100,000 population in England and Wales ranged from 55 to 84, in Salford the range was 114 to 178 (The death-rates from pneumonia, pulmonary tuberculosis, and lung cancer were all higher in that smoky city than in England and Wales, though the differences were less striking) This implies that the death-rates from bronchitis are very high in Salford—not that they are low in England and Wales in fact they are about 3 times those of Belgium, 6 times those of Germany, 15 times those of France and Scandinavia, and 36 times those of the United States Chronic bronchitis may well now assume the mantle of the vanishing rickets and be called " the English disease " " Men in England awaking and clearing their bronchi before setting out to work make a fearful noise"[3], and in 1956, bronchitis accounted for 5 6% of all the deaths in England and Wales (11 9% in Salford) Moreover, it is the cause of about a tenth of all the days lost from work through illness, and it cost the National Insurance Fund £$7\frac{3}{4}$ million in one year

Admittedly no certain link has been established between air pollution and bronchitis or other respiratory disease, but the epidemiological evidence is very strong [4–7] Smoking aggravates bronchitis, and fog, temperature inversion, and influenza precipitate a rise in the number of deaths (the relationship with influenza epidemics may partly account for the tendency of the death-rate from bronchitis to rise and fall in alternate years) Clean air may come, one day, as a by-product, when nuclear fusion provides most of our power, but many years may slither away before then To use the prospect as an excuse for inaction will cost very many lives and much misery We may wish that our ancestors had not left us with such a legacy of inefficient smoke-emitting devices, but, to quote Dr Hilditch [1] again, " we must make the best of the situation as it exists and improve our environment whenever and wherever we can "

The Clean Air Act lays on local authorities much responsibility for making these improvements, and we hope they will do more than they have yet done [8] to make use of their splendid opportunities of improving our health The fact [2] that the bronchitis death-rate in Japan fell from 44 8 per 100,000 in 1947 to 9 9 in 1955 is both an example of what can be achieved and a stimulus to inquiry as to how it was done

NINETY

IN deciding when to publish an article, we seldom make any serious effort to ensure that it shall appear on the author's birthday But we felt that an agreeable adventitious flavour would be given to Sir Leonard Rogers' latest contribution if we kept it for this week For he was born on Jan 18, 1868

We must wait another ten years before asking Sir Leonard the routine question about the reason for his exceptional longevity, but the explanation certainly cannot be an inactive life His astonishing output of original work comes of a combination of native wit with intense labour His strenuous application to the matter in hand, from his earliest days in medicine, seems to have preserved, instead of impairing, a youthfulness of mind which still enables him to rely on his remarkable memory for detail when he speaks, without notes, on medical subjects Regarding him as a contemporary, we may find it hard to remember that this is the man who introduced emetine for amœbiasis, antimony for kala-azar, and chaulmoogra preparations for leprosy, and who revolutionised the treatment of cholera before he turned his mind to the forecasting and prevention of this devastating disease, on which he is again making important practical proposals Because he is so keen, he has a persuasive habit which gained from many sources large funds for the Calcutta School of Tropical Medicine and later for BELRA—the British Empire Leprosy Relief Association His work has been his passion, and his conversation, as eager and rapid as ever, is of his work, his ideas, and his sons He speaks as he is, a leader of thought and action, but he is never pompous, and his humour remains He has enjoyed his life, as his autobiography *Happy Toil* makes very clear, and we wish him many more years in which he can use his genius to stimulate his juniors

FORECASTING AND CONTROL OF CHOLERA EPIDEMICS IN SOUTH-EAST ASIA AND CHINA

Sir Leonard Rogers
K.C.S.I., C.I.E., M.D. Lond., LL.D. Glasg., F.R.C.P., F.R.S.
FORMERLY MAJOR-GENERAL, INDIAN MEDICAL SERVICE

In a recent paper (1957) I recorded a tenfold reduction in the cholera mortality during the decade 1946–55 in the extensive endemic area of Lower Bengal—the home of cholera—together with a forty fold to fifty fold reduction in the more extensive epidemic areas of India, including the practical elimination of the disease in the Punjab and North-West Frontier provinces

This unprecedentedly rapid decline in cholera mortality coincided with the general adoption of my suggestion of 1926 and 1928 to inoculate compulsorily the 20 million or so pilgrims, whom I had shown to have played a predominant part in disseminating cholera every year in epidemics over India, and in exceptionally bad years as pandemics over Asia and Europe, &c., during the 19th century

During the fifteen years 1941–55, about 300 million people were inoculated against the disease in India, but during the first five of these years the second world war led to shortage of food and famine conditions, which are always accompanied by a greatly increased cholera incidence, due to widespread movements of the people in search of food These circumstances prevented the full effects of the new plan of control being obtained during 1941–45 The continued use of the new measures during the decade 1946–55 doubtless had a cumulative effect It should be noted that they have still to be tested after widespread failure of the monsoon rains, with inevitable increased cholera incidence (Rogers 1928, pp 27–40) It is, however, a hopeful sign that after a failure of the north-east monsoon rains in the last quarter of 1936, the increase of cholera in South-East Madras was a comparatively mild one

The success of control measures in India led me to extend my epidemiological inquiries to the incidence of cholera during the first half of the present century in South-East Asia and China, in the hope of extending preventive measures over these areas

It was first necessary to establish the areas where the disease is endemic at all seasons of the year because the monthly absolute humidity (i e, the mean water-vapour pressure) does not fall below the critical minimal point of 0 400 in Hg during the winter months, as I showed to be the case in India (Rogers 1926, 1928)

The table shows that in Burma, Thailand (Siam), and Indo-China the lowest early absolute humidities of January and February remain above 0 400, so these are endemic areas Burma is continuous with the endemic areas of Assam and the eastern provinces of Greater Bengal, from which cholera epidemics spread yearly over North-West and Central India, coincidently with the spring rise of the monthly absolute humidity to well above 0 400 The combined endemic areas of Bengal and South-East Asia, as defined above, are indicated by the hatching in the map (fig 1)

On the other hand, China is a huge epidemic area in which the winter absolute humidities fall well below the critical line of 0 400 from November to March from the Yangtse valley northward, as shown by the monthly data of Shanghai near the mouth of the Yangtse river The readings for the southernmost part of China, as illustrated by those at Hong Kong (in December, January, and February 0 405, 0 390, and 0 387 respectively) are on the borderland of the critical point Southernmost China thus corresponds to the eastern sub-Himalayan North-West province of India (Rogers 1928 map VIII, p 222) in being a borderland area where cholera is reduced to very small proportions during the winter, but recrudesces in March with the rise of the absolute humidity to over 0 400 Later the cholera spread farther to the north-west with the rise of the absolute humidity to well over 0 400 just as it does over Central and Northern China in epidemic years

It was therefore necessary to study the annual incidence of cholera in South-East Asia, its possible connection with the Bengal endemic area to the west, and the spread north over China in epidemic form For that purpose the available data from 1900 to 1955 have been collected, and the annual death-rates per 1000 are shown in the chart (fig 2), so as to be comparable for India, Burma, Thailand, and Indo-China The chart also shows the years in which epidemics of cholera spread over China, of severity graded I, II, or III (Wu Lien-Teh 1932)

Grade III includes the most serious epidemics, in which the disease spread over nearly all China as far north as Manchuria and Korea Grade-I epidemics were limited to South China, and grade-II were intermediate, with involvement of Central China and the Yangtse valley In the remaining years there were no widespread outbreaks, and only a small mortality from the disease in the extreme south of China, bordering on the endemic area of Indo-China, and in ships coming from southern endemic areas

The Spread of Cholera from India to Eastern Asia

Before the data shown in the chart are considered, a brief summary must be given of the spread of cholera over Far East Asia in pandemics during the 19th and 20th centuries

The earliest was recorded in the latter part of the 19th century by John Macpherson (1872) But the most striking was that of 1840–49, described by N C Macnamara in his classical *History of Asiatic Cholera* (1876), and illustrated by a map in my *Cholera and its Treatment* (Rogers 1911) Cholera was then carried by sea to China, and spread inland across Central Asia to reinvade the Punjab from the west and Upper Burma from the north, contrary to the general rule The 1861–62 pandemic was also carried by the sea route to overrun China

Since the endemic areas of Assam and Bengal are contiguous with Upper and Lower Burma respectively, we must study the

annual medical reports of Burma for evidence of cholera spreading eastwards from India This is limited by the absence of any good road or railway communications between Assam and Burma, to the north by a mountainous area blocking the east end of the Brahmaputra valley, and to the south from the Chittagong district of Eastern Bengal by hilly country Nevertheless a study of many annual medical reports of Burma reveals that some 300,000 labourers travel yearly to Lower Burma from Eastern Bengal, and they have been known to spread cholera during the spring rise in the incidence of the disease Such outbreaks of cholera in Lower Burma should be controlled by the annual inoculation of such dangerous immigrants

Moreover, although pilgrim traffic is on a much smaller scale in Burma than in India, there are a number of yearly festivals at the Burmese pagodas attended by some 280,000 pilgrims, who have frequently spread cholera outbreaks They also should undergo compulsory inoculation every year, in view of the striking success of that measure in India in recent years

Cholera Incidence and Meteorological Conditions

The data shown in fig 2, which include material failures of the monsoon rains, must next be studied in the light of recent experience in India to ascertain whether epidemics of cholera in East Asia can be foreseen in time to allow of their being controlled by measures that proved effective in India

The upper section of the chart reveals six years in which cholera epidemics of grade III spread over China from the south as far north as Manchuria The first of these epidemics, in 1902, originated in the great Indian epidemic of 1900, which, as usual, followed widespread failures of the south-west monsoon rains in June to October of the previous year The recorded deaths from cholera in 1900 in India were 797,273, or 3 72 per 1,000 of the population This epidemic involved Burma in the same year, during 1901 and 1902 it spread eastward over Thailand and Indo-China, and was still prevalent in southernmost China in 1903 Hong Kong, the Straits Settlements, and the Philippine Islands were also involved

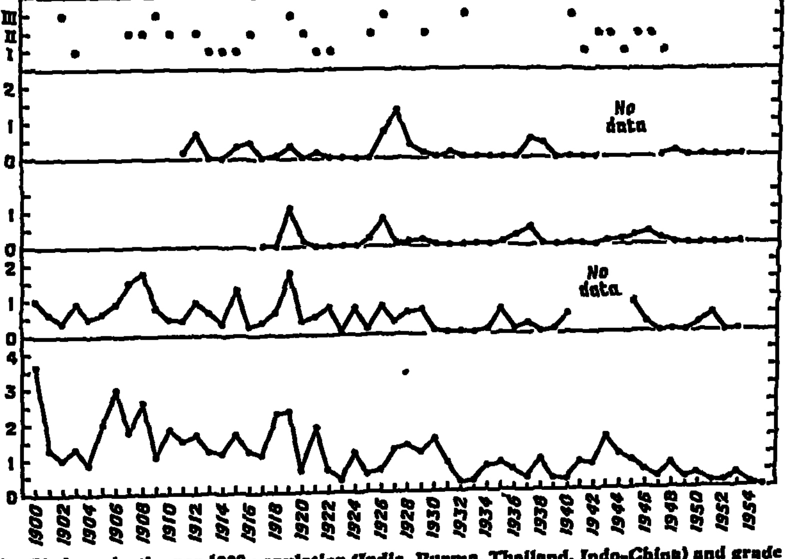

Fig 2—Cholera deaths per 1000 population (India, Burma, Thailand, Indo-China) and grade of epidemics (China)

In the 1906–09 epidemic, India was involved in 1906–08, with cholera mortalities up to 1 43–1 68 per 1000, and China had grade-II outbreaks in 1907 and 1908, culminating in a grade-III one in 1909 extending as far north as Manchuria once more Hong Kong, Singapore, and the Philippines were also involved It is noteworthy that in China the 1907 summer monsoon rains were deficient—a shortage that almost always precedes cholera epidemics in India by resulting in scanty drinking-water supplies during the succeeding annual spring rise in cholera incidence

In the 1918–20 cholera epidemic India showed the high cholera mortalities of 2 35 and 2 40 per 1000 in the first two years Burma had the high rate of 1 53 in 1919 and Thailand one of 1 13 per 1000, the highest of the past half-century, with 10,277 deaths from cholera In Indo-China the rate rose to 0 27 per 1000, and a grade-III epidemic once more spread north over China to reach Manchuria It continued as a grade-II outbreak in central and south China in 1920, and as grade I for the next two years in south China only, with absolute humidities of January and February of almost 0 400

The 1924–26 epidemic ran a very similar course to that of 1918–20, for the cholera death-rate rose in 1924 in both India and Burma and was followed by increased prevalence in Thailand in 1925 and 1926 and in Indo-China in 1926 and 1927, to reach the highest level in the series of years of 24,201 deaths, 1 34 per 1000, in 1927 This epidemic culminated in a grade-II epidemic in 1925 and a grade-III one in 1926, reaching as far north as Manchuria It was again aggravated by a water shortage, the annual rainfall in Shanghai in 1925 was 13 85 in , or nearly a third of the normal

In 1932 another grade-III epidemic affected China as far north as Manchuria, but was exceptional in not having been associated with high cholera prevalence in the countries to the south, except for a moderate rise of 1580 deaths, or 0 18 per 1000, in contiguous Indo-China However, Wu Lien-Teh (1932) records that the first cholera death of this year was on the unusually early date of April 26, and the outbreak at Shanghai, near the mouth of the Yangtse, spread to the south and also north to Manchuria The disease must have reached the great port of Shanghai by the coastal route from the south, as it has repeatedly been recorded to have done in the half-yearly reports of the medical officers at the Treaty Ports of 1870 to 1885, of which I have made notes This serious epidemic involved 23 provinces and 212 large cities, but the actual number of deaths is not recorded It was predisposed to by the low annual rainfall—a sixth below the average—and the occurrence of the first case as early as April indicates an early spring rise in the absolute humidity favourable to the early spread of the disease These factors may account for the fact that there was an epidemic though Burma and Thailand had not shown any material increase of cholera in the previous year, as had preceded the previous grade-III Chinese epidemics already described

In the case of 1940–47 China epidemics shown in fig 2, few data are available because the second world war had involved both Burma and China This period was accompanied by high cholera-rates in Burma in 1940 and 1941 and in India in 1941–45 In India famine conditions followed greatly increased prices of food, famine-stricken crowds wandered over the country The lack of data for the cholera deaths in the war years is illustrated by breaks in the curves in the chart

The general conclusion is that cholera epidemics in China are essentially due to the spread of the disease from the endemic regions of Eastern Bengal, Burma, Thailand, and Indo-China (in years of increased prevalence of the disease) across the southern border of China over greater or less areas of that vast country

Relation of Cholera Incidence in Burma to Meteorological Conditions

The incidence of cholera in Burma from 1877 to 1922, in relation more particularly to rainfall, is dealt with in my memoir (Rogers, 1928, pp 156–162) It is there recorded that in every one of the fifteen years in which the cholera incidence was 50% or more above the yearly average, the rainfall during the preceding south-west monsoon of June to September, or during the succeeding October to December, or during both periods, was seriously in defect Tables (Rogers, 1928, pp 147, 149, and 151) show that the same relationship holds good in the adjacent endemic areas of Eastern Bengal and Assam In all these areas the minimum cholera season is during the abundant rains of the south-west monsoon—e g, in Lower Bengal only 4% of the total annual cholera mortality is recorded at this season Exactly the opposite is the case in the epidemic areas to the north-west and west of Bengal, with absolute humidities below the critical point of 0·400 in the cold-weather months As in the endemic areas of Lower Bengal and of Burma to Cochin-China, the absolute humidity during the cold-weather months never falls to the critical level In these regions the annual rise in the cholera incidence starts in October to December, immediately after the cessation of the monsoon rains Hence the early failure of the monsoon and of the rainfall of the last quarter of the year results in the early and continued rise of cholera incidence in October and November, with high total incidence in the twelve months from October onwards Such years of high cholera incidence can thus be foreseen, though only very shortly before their occurrence From the extensive endemic areas of Lower Bengal, Assam, and Burma to Cochin-China, the epidemics spread to the west of Bengal over the epidemic areas of India and from South-East Asia northward over China, but only with the rise of the absolute humidity to well above the critical point of 0·400 in March to May in India and from late April onwards in China more particularly in the Central and Northern provinces This allows ample time for large-scale preventive inoculations to be used to protect China from the spread of cholera from the endemic areas to the south

Recent Cholera Incidence in India, South-East Asia, and China

The incidence of cholera has declined since 1947, with the exception of a rise in Burma in 1951 following deficient south-west monsoon rains The great decline of the disease in India has been shown to be due to compulsory inoculations on a large scale, but this explanation does not apply to Burma, where the latest data from 1947 to 1956 show an average of only 202,000 annual anti-cholera inoculations—very small figures in proportion to the population, as compared with those in India during the same period Moreover, the data show clearly that in years of low cholera incidence in Burma the inoculations fell to an average of under 50,000, this indicates that the inoculations were used extensively during outbreaks only when it was too late to control them

On the other hand, recent years have shown an unusual number of good monsoon rains, unfavourable to enhanced cholera incidence, in both India and South-East Asia, which cannot be expected to continue much longer Moreover, my studies of all the available Indian data from 1866, now extending over ninety years, show that very low cholera incidence in one year is liable to be followed by high rates whenever deficient monsoon rains favour a recrudescence of the disease, so preventive measures must be considered

Control of Cholera in the Endemic Areas with the Prevention of Spread over China

All sanitarians will agree that the ultimate control of cholera depends on the provision of safe drinking-water to the million or so villages of India and probably still larger numbers in South-East Asia and China The number of decades—or should it be centuries ?—that will be needed for that purpose is anyone's guess Meantime the authorities should consider the application to Far East Asia of the large-scale compulsory inoculation measures that have already met with success in India

The principles of the new plan of control are simple, but their application will vary to some extent with local conditions Thus in India the main task was the yearly inoculation of some twenty million pilgrims, who travel long distances through cholera-infected districts to attend religious festivals, become infected, and carry the disease back to their own villages On the other hand, there is very little spread of cholera by coastal sea traffic, which is a feature of its extension into China from the south All immigrants into China from the more southerly endemic areas should be inoculated against cholera at least a week before they are allowed to enter Chinese territories, preferably before embarking for the journey In the case of ocean-going steamships, this is probably already provided for Its great value is demonstrated by the long established inoculation of vast numbers of pilgrims to Mecca, which has put a stop to the spread of pandemics by them to South-East Europe, which were a feature of the 19th century A more difficult problem is presented by the extensive movements by coastal traffic of small vessels and by the large boating population in the estuaries of the great rivers of China Quarantine measures have for long been in use in Chinese ports, and judging from recent Indian experience, the advantages of regular large-scale anti-cholera inoculations are very soon realised by the people and have even led to their clamouring to be inoculated against cholera before undertaking journeys in cholera-infected areas This should obtain still more if it also avoids quarantine measures, which are far more unpopular

The appearance of cholera cases in vessels arriving in the more southern Chinese ports used to be a regular annual event, but the most serious epidemics have usually been due to overland spread in years of high cholera incidence in the endemic areas, as shown earlier It is also on record that quarantine methods have always failed to avert such spread overland The Chinese Government now have control of the northern portion of Indo-China, this will facilitate their control of the extension of cholera over southern China But to avert the more serious epidemic spread it will be necessary to keep a close watch on the development of high incidence of the disease in the cold-weather months, in Burma more especially, following deficient rainfalls during the preceding south-west monsoon and autumn period This can now be done, owing to issue in recent years of the weekly bulletins of epidemic diseases by the World Health Organisation

But to strike at the root of the problem it is essential that the endemic regions of Burma, Thailand, and Indo-China should adopt the successful Indian plan of enforcing compulsory inoculation every year of all pilgrims, immigrants, and other travellers from without and within their territories This measure will require about a decade to bring about its full effects But success should result, not only in the control of serious outbreaks in the territories concerned, but also in the prevention, in future years with extensive failures of the summer monsoon rains, of the pandemic spread of cholera over both Asia and Europe One more scourge of humanity will then have been brought under control by medical science

Conclusion

The incidence of cholera during the last half-century in the endemic regions of South-East Asia, and its epidemic extension northwards over China, have been studied The adoption is advised in Far East Asia of the large-scale compulsory inoculations, which have already greatly reduced cholera mortality in India during the past decade

I desire to acknowledge my great indebtedness to Sir Graham Sutton for supplying me with extensive meteorological data, to Dr Wu Lien-Teh for the loan of his valuable papers on cholera in China, and to Dr Charles Wilcocks and Mr Cyril C Barnard, both of the London School of Hygiene, for much help in obtaining literature on the subject

Points of View

MEDICAL PRACTICE IN A CHANGING SOCIETY*

Sir Francis Fraser
M A Cantab, M D, LL D Edin, F R C P, F R C P E
PROFESSOR EMERITUS OF MEDICINE IN THE UNIVERSITY OF LONDON, DIRECTOR, BRITISH POSTGRADUATE MEDICAL FEDERATION

New problems and new solutions are continually arising in our society Nothing is static Medical practice influences social conditions, and these in turn affect medical practice

Liberalism and Socialism

In the past half-century, side by side with the advances of science and their effects on our way of life, there have been two less tangible developments which have directed the policies of government and of all who have power to influence our thoughts, our ethics, and our morals These are the acceptance of liberalism—using that word in its widest sense—and the partial acceptance of socialism

By liberalism I understand the recognition of the value of the human personality—the belief that the individual human being should be free to exercise his peculiar abilities and energies, and that everybody has equal right to this freedom, regardless of social class or race To put it shortly, liberalism insists on the brotherhood of man and is inspired by the Christian ethic Not only has liberalism been accepted and cherished by this country, but it is generally accepted as the guiding principle of what we at present call Western culture It is in no way a new principle, but it was not generally accepted fifty years ago Today, though the best way and rate of implementing it is still a matter of debate, all three political parties in this country accept it without question The educational reforms have been inspired by it, the gradual narrowing of class distinctions is the result of it, and the gradual loss of the privileges of birth, and to some extent also of wealth, are the direct results of its acceptance

In strong contrast to liberalism, with its insistence on the paramount importance of the individual, are the principles of socialism These lay stress on the importance of the group, of the community, of the herd, and insist that the direction and control of our way of life should be in the hands of the community and ultimately of the State, the interest of the individual being secondary The socialist idea has been partially accepted as essential for successful government in these times of intense economic competition between nations Its progress is largely the outcome of the second world war when the best use of all our resources was a necessity, and centralised direction and control was the only means of coordinating effort From these war experiences arise the almost obsessional clamour for planning, with the risk of totalitarianism and an oppressive bureaucracy

Between the doctrines of liberalism and socialism this country continues to compromise with its traditional skill

One present result is the Welfare State, with its National Health Service, retirement pensions, insurance against unemployment and accident, subsidised essential foodstuffs (especially for pregnant mothers, infants, and schoolchildren), free education, holidays with pay, legal assistance, housing subsidies, and so on And to pay for all this we have crippling death duties, supertax, and a very high rate of income-tax especially on unearned incomes, which have removed any lingering vestiges of the feudal system and have almost abolished the landed aristocracy

Science and Technology

The most obvious effects of science and technology on our standard of living and way of life come from the application of metallurgy and chemistry and electronics in the factory and in the home But perhaps the greatest influence on our lives has been the development of what are generically termed communications—facilities for more rapid travel, the telegraph, telephone, wireless, and television, the cinema and the daily press Through the printed or the spoken word, by visual demonstration, or by seeing for himself, each of us is kept closely informed of what is happening in any part of the world, and these events crowd on us daily or hourly A person can no longer confine his interests to his immediate surroundings no longer does his family and his work group provide him with all the incentives and reasons for his physical and intellectual activities Fifty years ago he was the member of a family and of a village community, or the citizen of a town, but now he is being gradually forced to see himself as a citizen of the world, who must share in the problems of his fellow men, no matter where they live or to what race they belong The raw materials required in his work, essential for his continuous employment, may come from many countries and continents, and in order that the products of his work may be sold there must be not only a demand but also purchasing-power in countries that until recently he had never heard of In the words of A H Compton, chancellor of Washington University in St Louis

---

* From a Pfizer postgraduate lecture to the Glasgow faculty of the College of General Practitioners

> " One important change in our mode of life is that the contacts of person with person are becoming more frequent and more extensive This growing interdependence is a part of the process of becoming more civilised At present we find ourselves becoming members of a world community Thus the community to which one belongs is extending more and more widely until already in many of its aspects it embraces all of mankind " [1]

The influence on our way of life of these ethical and political principles and of the discoveries of science has been great, and is still active The conditions are constantly changing and there is no sign of any slowing of the rate of change—no indication that we are nearing a stage of stability and security

Changing Foundations of Medical Practice

Science and technology have affected the practice of medicine as much as they have affected social conditions There have been great advances in preventive medicine, in diagnostic accuracy, and in therapeutics, and the general picture of practice has changed both for the family doctor and for the specialist

More perhaps than any others, two advances are responsible for this change in the picture one is the control of infections by means of the sulphonamide drugs and the antibiotics, and the other the increasing range of surgery, largely due to the dramatic improvements in anæsthesia By control of infections and by successful surgery we can remove many of the basic causes of ill health or of death , and this should, of course, always be our aim, though for most of our patients we still have to rely on the treatment of symptoms and any other aid we can offer while they recover their health and capacity, or fail to do so

Besides the advances that enable us to remove the causes of ill health, there are others that help us to control abnormal processes or so modify the symptoms of disease that our patients can more readily recover, or at least continue in gainful occupation In this category I need only mention the hypotensive drugs, the anticoagulants, the analgesics, hypnotics, sedatives, tranquillisers, and diuretics, and we look forward to the further development of treatment by synthetic hormones

In diagnosis also, scientific advances have been impressive The most important are the analyses of biochemical processes, in which the use of radioisotopes have proved a valuable tool More obvious perhaps has been the development of radiodiagnosis to disclose the structural causes of disturbances of functions The use of X rays and contrast media and of cardiac catheterisation allowing the clinician to define the lesions in diseases of the heart and circulation with the accuracy necessary for cardiac and vascular surgery, and similar developments in the diagnosis of diseases of the lungs and bronchi are essential to the increasing successes of thoracic surgery Less dramatic perhaps, but no less intellectually satisfying are the advances being made by the hæmatologists

The use of the scientific method has made the practice of medicine—preventive, diagnostic, and therapeutic—become more precise For many of our patients we can now do much more to save or prolong their lives or to help them to live with their abnormality

An analysis of clinical medicine stated by Wilfred Trotter some years ago is, I think, worth recalling at this time He pointed out that clinical medicine includes an experimental science—a strictly scientific discipline—which requires that no conclusion be reached till the evidence is complete, but that for the most part the practice of medicine is composed of applied science, and a practical art As I have indicated, the application of scientific discoveries to clinical medicine is a part of practice that is growing now at an increasing rate But there remains the third constituent—the practical art by means of which we care for our individual patients, based on the experience of similar situations, on a cultivated intelligence, and on a knowledge of human beings For its successful exercise, it requires sympathy with human suffering It is founded on the personality and character of the practitioner and it cannot be taught, though it can be greatly encouraged by the example of teachers and senior colleagues The same now as it was in the days of Hippocrates, this personal component of clinical medicine will be required in the future as in the past

The Individual and the Changing Society

Much has been written of late years about the absence of real happiness, joy, and satisfaction among our people—in spite of the Welfare State, in spite of better physical health, in spite of all the labour-saving and increased leisure that applied science is giving us From a variety of standpoints, the writers all agree that the situation is serious and that it results from the rapidity of the change in conditions of our society They point out also that these changes and developments, in so far as they are the result of conscious design, are failing to produce the very benefits intended—namely, a fuller and a happier life for each individual

Man is the most highly developed member of the animal kingdom and it is his nature to be continually seeking outlets for his endeavours, he cannot remain static, but feels an urge to progress and to develop the potentialities of his personality For this he needs freedom At the same time he is a social animal and can develop successfully and happily only in cooperation with other human beings, other personalities He is assisted in this by the advances in science and technology which enable the life of each to become more closely identified with the life of mankind, but his ties to his family and to his local community have become looser

At the beginning of this century the codes of behaviour acquired in the family circle and later at school and elsewhere were based on a long tradition, in which religion and pride of place in the community played considerable parts People looked forward to a life in which these foundations gave stability, their futures were relatively secure, and their relations with their fellows followed a recognised pattern Wider educational horizons have shaken the trust of the adolescent in the values and traditions of the family It has been pointed out that the parent-child conflict is intensified during periods of accelerated change, and as Eisenstadt [2] puts it

> ' The transition from family to total society is necessarily fraught with severe emotional difficulties, as it necessitates redefinition and transformation of the individual's role expectations '

---

[1] Compton A H *Proc. roy Instn G B* 1955, 35, 788

[2] Eisenstadt, S N From Generation to Generation London, 1956

These emotional difficulties affect both the child and the parents

Instead of receiving their moral, ethical and behaviour values from the family and the local community, adolescents, and adults also, now get them from many different sources—trade-unions, the Press, wireless, cinema, age-groups, clubs, the Army, and so on These present a great variety of experiences from many countries with various cultural standards and competing values, many of which cancel out each other, and man lacks the psychological certainties of custom and precedent to guide and steady him

In his *Diagnosis of our Time*, Karl Mannheim [3] says

> "We should not forget that moral codes, like legal regulations, are devices for moulding human behaviour If we have so far been able to do without institutionalized control in the moral field, this is mainly because the ethical standards of everyday life have been created for the most part by trial and error, and transmitted by anonymous tradition But trial and error only work as long as social conditions favour unconscious selection that is, as long as changes take place so gradually that unworkable norms are sloughed away in the course of time *This is not what is happening today* The speed of transformation is surely too great to permit unconscious experiment and selection The individual is lost in an invisible society, and is too weak to invent new norms for himself The result is moral chaos in which religious standards, family traditions and neighbourly ethics are losing ground without being replaced by other principles"

and again

> "The most fruitful methodological device in science, namely to adjust if necessary our whole system of thought to the ever-broadening sphere of experience, becomes when applied to human life and moral issues, the greatest predicament of modern man By developing the same kind of dynamic rationality in the moral world, modern man tends to lose a firm basis on which to stand Whereas in some prominent individuals this falling into the abyss of the self without reaching the bottom presents itself as a grandiose struggle, in the average man the very same dynamics lead to a frivolous attitude of believing in nothing and to an endless craving for new sensations"

The average person, then, is suffering from the loss of the sense of security that arises in the absence of accepted standards of behaviour and of moral codes, but the changing social conditions are interfering also with the human urge to assert his individuality and to contribute his own peculiar talents in cooperation with his fellows Even a partial acceptance of the principles of socialism induces uniformity Man is moulded to a pattern by the education in the local-authority school, and in his work he must conform to the dictates of his union, the decisions of which he may have little, if any, say in determining Service with the Armed Forces emphasises the same trend The more the central planners are able to regulate our lives, the fewer are the opportunities of men and women to develop their talents and personality, and to progress

Sir Alexander Gray [4] has expressed this concisely

> " and Planning, as now understood, means among other things the removal from the decision of the individual or the electorate to the decision of the expert who is, by definition, always right"

and he concluded

> "I suggest to you, hesitatingly and for your consideration, that the Welfare State, in its unbounded benevolence, may find itself driven to a degree of regimentation and control which would make it in essence a government at least mildly totalitarian in character"

Though adoption of the principles of liberalism and socialism, and the advances of science and technology, are bringing enormous improvements in man's way of life and in the social conditions of this country, these are largely material and have been accompanied by a loss of stability and of the traditions that gave to each individual a sense of security The average person feels frustration when hemmed in by regulations he becomes restless and can find no outlet or relief It becomes harder for him to cooperate with those with whom he is in contact in his work, and even in his home These mental stresses so affect him that sooner or later his efficiency and his bodily health may suffer Before long he seeks the help of his doctor

The Changing Practice of Medicine

We saw how the advances of science have enabled us to be more precise and definite in the diagnosis of disease processes and to apply curative or corrective therapy to an increasing degree over a continually expanding field It gives us intellectual satisfaction and professional confidence to be able to help those patients in whom the disturbance to health and well-being can be so dealt with But perhaps we are, in consequence, less ready to spend our time and our energies on those patients whom we cannot help so directly, so dramatically We may be tempted even to be less sympathetic towards them It is disturbing to hear so often from members of the public "I didn't tell the doctor about that, he seemed too busy", or "I told the doctor, but he paid no attention to that"

It is well to take for granted that every patient who decides to visit a doctor feels fear or apprehension in some degree Only rarely is it fear of death, but usually there is fear about inability to hold down a job, or to manage the household, or to look after the children, or perhaps merely to get the best out of life, and the mother's worry for a sick child can produce a strong and deep emotional upset It is also a good rule in clinical medicine never to be satisfied with what has been done for a patient until the evidence is sufficient for a prognosis to be given, even if it would be unwise to state it The prognosis is the answer to the question, often unspoken, "What does this mean to me ?" or "What does this mean to my child ?" Exclusion of organic disease does not in itself justify the diagnosis of a stress or psychogenic cause If such a cause exists, the prognosis will depend on whether or not it can be eliminated or its effects modified, and for this to be possible it must be tracked down No-one is more competent to do this than the family doctor with his previous knowledge of the patient, of the home, and of the other members of the family Moreover, the therapy required for most of these patients needs no psychiatric specialist or expert training, common sense and a knowledge of the family and their environmental conditions are more valuable, and above all human sympathy and a desire to help and serve our fellow human beings—the essence of the practical art of medicine

The obvious difficulty is, of course, that all this takes up precious time which the practitioner may feel would be better spent on patients suffering from more definite disease and for whom we can do something specific and up to date But often more time can be found by better organisation of the work

For example, P M Higgins [5] describes how the institution of an appointments system and a shift system for himself and his four partners eased the pressure on their time and accommodation J G Ollerenshaw [6] shows how office work can be handed over to a receptionist and secretarial staff, and better use made of the services provided by the local health authority. Many practitioners, I think, are unaware of the help their local authority is prepared to give, and the more cooperation he establishes with the hospital service and his local authority the more time he will have to give to those patients whom he can best serve.

[5] Higgins, P M *Lancet*, 1957, i, 680

[6] Ollerenshaw, J G *Med World*, 1957, 86, 251

If the little enough time now available for leisure and recreation is not to be curtailed, clinicians should rid themselves of every task that can be performed as well, if not better, by others. In this way only can they meet successfully the challenge of a changing society. I must add that the most obvious means of getting more time to deal properly with the fears, apprehensions, and mental stresses of our patients is for each doctor to have fewer patients for whose care he is responsible, and this some doctors are doing.

Our profession has been accorded a peculiar privilege that distinguishes us from members of all other professional groups. This privilege has been given to us not by the State but by the people. They trust us and confide in us, and they ask us to relieve them of the burdens that unaided they find are too much for them. Because of this privilege, there is much more in the practice of medicine than the application of science. No matter how great the advances still to be made by the employment of the scientific method, there will always be a need for the practical art of medicine.

Conclusion

At present we are so busy preventing, diagnosing, and treating diseases that we have too little time left for treating our patients, for caring for them and relieving them of their burdens. But our patients are in greater need now than ever before of the care and devoted service that we have been especially selected and educated to give to them.

Medicine and the Law

Artificial Insemination not Adultery

CAN a wife who has borne a child as a result of artificial insemination be said to have committed adultery? This question came up for consideration recently in the Scottish Court of Session on the hearing of an action for divorce brought by the husband.[1] In a reserved judgment given last week, Lord Wheatley ruled that artificial insemination does not in law constitute adultery.[2]

The husband and wife had not lived together since March, 1954. In July, 1955, the wife gave birth to a girl. Her claim was that the child had been born as the result of artificial insemination through a donor, and that this was not adultery as the Law understood it. The husband maintained that he had never agreed to this course if in fact it ever took place, and that such a general defence was irrelevant.

Lord Wheatley, who described the case as unique in the annals of our Law, said that there were manifestly grave moral, ethical, social, and personal considerations involved in the practice of artificial insemination. It was almost trite to say that a married woman who was artificially inseminated in order to have a child who would not be the child of her marriage had committed a grave and heinous offence of contract of marriage, but the question for him to determine was not the moral culpability of such an act but whether it constituted adultery in its legal meaning.

His Lordship said that, having examined the Law of England on adultery and having found nothing to persuade him that the Law of Scotland was not the same on the subject, and having studied the opinions expressed by judges in other countries and in textbooks, he had reached the conclusion that artificial insemination did not come within the definition of sexual intercourse as understood by Scots Law. "Just as artificial insemination extracts procreation entirely from the nexus of human relationship in or outside marriage, so does extraction of the nexus of human relationship from the act of procreation remove artificial insemination from the classification of sexual intercourse. . . . it follows that artificial insemination by a donor without the consent of the husband is not adultery as the Law interprets that term."

This judgment is not binding on the English courts, but it will undoubtedly have great persuasive value and is very likely to be followed if the matter ever comes up for consideration in England. Although the two legal systems differ in some important respects, there is a tendency for the courts of both countries to follow each other's decisions if possible. Lord Wheatley's view that there cannot be adultery without actual sexual intercourse is in line with English judgments on the nature of adultery. Thus manual gratification by a wife of another man's sexual organs has been held not to be adultery, although a breach of the obligations of marriage. The distinction between adultery (which is a ground for divorce) and various other breaches of the responsibilities of marriage (which are not necessarily a ground for divorce) is cardinal to the whole subject, and should not be overlooked in the debate which will no doubt result from Lord Wheatley's judgment.

Public Health

Atomic Safety: a Report after Windscale

AFTER the accident at Windscale no. 1 pile last October, a committee, under the chairmanship of Sir Alexander Fleck, was asked "to review the organisation within the Authority as a whole for control of health and safety and to make recommendations." A summary follows of the committee's findings and recommendations.[1]

The accident revealed latent public anxiety about the risks of atomic-energy work. The precautions already applied were very elaborate, the aim must be to err on the side of caution. The accident revealed that the Authority's organisation was inadequate, but improvements in it must be supplemented by clarifying the relations between the many Government departments concerned with atomic safety, by coordinating the activities of these departments, and by building up the Atomic Energy Office to enable it to play the leading role. The measures needed for safety were formulation and observation of appropriate codes of practice, with numerical limits established by experiment and with monitoring of plant and operations by safety staff.

The hazards to be considered were exposure of workers to radiation, loss of control of a nuclear reactor (including unintentional assembly of critical masses), and discharge, as effluent or by accident, of radioactive matter.

The Authority's three groups (industrial, weapons, and research) should collaborate on problems of criticality, to ensure that a critical mass of material (i.e., that which leads to a nuclear reaction, giving rise to heat and fission products) was not assembled accidentally.

The committee agree with the Authority that an independent board should be set up to license nuclear reactors, but at present the only people competent for this were on the Authority's staff, and it must remain a long-term objective.

---

[1] *Times* Dec. 6 1957.
[2] *Ibid* Jan. 11, 1958.

[1] The Organisation for Control of Health and Safety in the United Kingdom Atomic Energy Authority. H.M. Stationery Office. Cmnd. 342. Pp 28. 1s. 3d.

Decentralisation of management in the Authority meant that health provision was not uniform The report endorses the Authority's decision to set up a committee responsible for overall supervision of all matters of health and safety The management of health and safety in the factories of the industrial group should be integrated into a single section responsible directly to the works general manager The health and safety manager should be a physician of consultant calibre, with sound training in industrial health, special knowledge of the health aspects of radiological protection, and some knowledge of the associated problems in physics, chemistry, and engineering If such a man could not be found, the best alternative would be a physicist with knowledge of the biological aspects

One of the most important points emerging from the committee's review was the serious shortage of people with the necessary qualifications in medicine, radiology, health physics, and nuclear physics and engineering Health and safety should be made an attractive career, with appropriate salaries and the provision of proper instruction The Authority "should assume responsibility for building up the national supply of these health and safety specialists, who will be required in ever increasing numbers" The specialised training provided by the Authority should take eighteen months, full time, including up to nine months' study of radiation physics The training should merit a new professional qualification The Authority should also recruit and train, on the job, the new special works medical officers, and offer training to public and industrial health workers, sanitary and water engineers, and the police This training should be carried out in a national centre, which would also cover the health and safety aspects of the use of isotopes in medicine, agriculture, and industry

The Authority should review the procedure for the publication of information about accidents, and coordinate the site emergency procedures and bring them to a uniformly high standard in all units

Londoners Last Year

A preliminary report on the health of the county of London in 1957 has been issued by Dr J A Scott, the medical officer of health The death-rate, at 11 2 per 1000, was the lowest (except for 1954) since 1948 Mortality was light in the mild first quarter, but there were 2000 more deaths than usual in the December quarter and the number of deaths from respiratory disease was twice the average There were an estimated 350 cases of poliomyelitis, with 12 deaths Tuberculosis mortality fell from 0 14 to 0 11 per 1000, and there were fewer notifications 23,000 children were vaccinated with B C G

The birth-rate rose, for the first time since the 1947 peak Infant mortality was 0 35 per 1000 births—the lowest on record, except for 1956 46% of pregnant women and 87% of children under a year attended the L C C antenatal clinics

The Third Quarter in England and Wales

The Registrar General has issued his report[1] for the quarter ending Sept 30 last. His figures for births, deaths, stillbirths, and infant mortality confirm those given previously[2] Other details include

Population and life expectancy—Abridged life tables are given, based on the mortality experience of 1954–56 The expectation of life in years for males (females in parentheses) is 67 6 (73 1) at birth, 68 6 (73 7) at 1 year, 50 3 (55 3) at 20, 31 4 (36 2) at 40, 15 0 (18 7) at 60, and 5 2 (6 2) at 80 Population tables show that males outnumber females in all age-groups up to 30, thereafter women outnumber men The total population at June 30 was estimated at 45,043,000, including 2,070,000 men and 3,196,000 women aged 65 and over

Infectious diseases—The death-rate was 96 (91) per million from tuberculosis, 392 (267) from pneumonia, and 9 (3) from poliomyelitis (figures for third quarter of 1956 in parentheses) Smallpox caused 2 deaths, the first since 1953

In England Now

A Running Commentary by Peripatetic Correspondents

With some thousands of other citizens I spent last Wednesday evening "just messing about in boats" At Olympia there were hundreds of boats, large and small, round and flat, black and white, glass (yes glass) and wood, driven by air, oar, and diesel They must have knocked the wall down to get some of them in, or else built them there complex rigging soared skywards and was lost in the smoky haze around the second-floor gallery At the other extreme sailing dinghies shrank to pram dinghies and canoes for achondroplasiacs finally there was a sort of folding boat that could be carried in one hand like a bag Doubtless there was an inflatable boat somewhere that fitted snugly into the vest pocket Lifeboats, patrol-boats, and even the Armed Services were represented, one remarkable boat had rotors fitted with which the thing could fly in the air But I didn't see a single raft True there was a *minute canoe about 8 in across in which some madman* crossed the Atlantic But no rafts shades of Kon Tiki and Jerome K Jerome Or maybe rafts are just a little bit *too* easy to make yourself in the back garden and not worth plugging A splendid nautical atmosphere was created by the sounds of distant breakers and B B C seagulls coming out of the diffusion system

The clientèle looked rather dull just like the people that go to the Radio Show, the Photographic Show, the Motor Show, and even our little Show There must be a nucleus of people that attend all exhibitions for the heck of it without being especially interested why of course there's me for a start But the odd beard sprouting a curly pipe and covering a duffle coat suggested that some yachtsmen were present, and I heard one splendid salty character, a lifelong yachtsman to the tips of his bushy eyebrows, remark "Quite a good show all round—but too many d——d engines"

After an hour or two one gets a surfeit of seafaring gallery after gallery of stoves, lamps, rudders, binnacles, and blocks stretch ahead The salesmanship could learn a thing or two from our little show nobody invited me to heave to and prepare to board, and I couldn't even cadge a sample tin of waterproof paint So after taking on ballast at the canteen we luffed windwards to the exit feeling slightly seasick

* * *

After the effects of turkey and cigar amblyopia had abated I settled down to analyse our Christmas-card series 11% boasted holly, 11% Father Christmases (3 with reindeer and 3 using more modern means of transport—car, train, and sputnik) 10% showed a winter scene, but the orthodox seasonal balance was upset by 1 autumnal picture and 1 view of summer in Sydney (Australia) Food (mainly puddings with some of the 11% holly stuck into them) formed 7% Coaches and carol-singers were surprisingly poorly represented (3% each) and robin redbreast was a melancholy single entry Angels (3%—*1%* with tenor saxophone), *flowers* (4%), and simple unheraldic crests (4%) were significant The most bizarre single entries are not included in the present series, but they included an etching of Frankfurt am Main, a blonde hanging up nylon underwear, and a photograph of a Nigerian woman fishing in the Limbe River We shall have to wait till next year to see whether these are statistically significant

* * *

One of the pleasantest English sports is catching trains It is so democratic And it has all the thrills of surprise and suspense It induces such sympathetic participation in the spectators Only the most antisocial refuse to enjoy the triumph of the train-catcher Rarely, you get the exquisite sensation of watching an artist *How unruffled he is How elegant* and perfectly coordinated are all his movements as he darts through the barrier and springs lightly on to the moving train You sink back into your seat with some of the afterglow that *follows Spectre de la Rose*

---

[1] Registrar General's Quarterly Return for England and Wales Third Quarter, 1957 H M Stationery Office, 1957 Pp 24 1s 6d

[2] See *Lancet*, 1957, ii, 887

As a warning to would-be emigrants to Canada I should like to quote from our railway by-law no 99, approved by the Board of Transport Commissioners for Canada and sanctioned by His Excellency the Governor-General-in-Council

> No person, except a servant or agent of the Company in the performance of his duty, shall open any vestibule door or stand upon the steps or platform of any car while it is in motion, or entrain on or detrain from, or attempt to entrain on or detrain from, any such car while it is in motion

And in case anyone may think that a railway by-law means nothing, like no-smoking in English trains, they make it physically impossible to do what the by-law prohibits Bars of steel lock all the doors before the train moves

On board the train your safety is still the commissioners' main concern, even if you have villainously boarded the train without a ticket

> Every passenger who refuses to pay his fare or produce and deliver up his ticket upon the request of the conductor, may, by the conductor of the train and the train servants of the Company, be expelled from and put out of the train with his luggage at any usual stopping-place, provided that the conductor shall first stop the train and use no unnecessary force

The by-law that prevents you from leaping on to the moving train saves you from being flung off it, without your luggage, at some uninhabited spot Too many romantic souls think of Canada as a wild, lawless, rough-riding, sharp-shooting territory If train-catching is your sport, you'd better stick to the Euston Road

* * *

In the West of England hospital where I was reared the loudspeaker caller system for members of the staff is unknown, and before I came to St. Euphonia's I had only come across it in American films

It has various aspects that fascinate me There is the Voice From Heaven impression. This feeling of being personally called to Judgment every few minutes wore off after a while However, I still sometimes give an involuntary shudder when I hear my name called in a voice of doom, from outer space as it were

The impression that has lasted, on the other hand, is that of being part of a cosmic game of Happy Families "Calling Mr Sparks, the Electrician", or "Calling Mrs Potts, the Domestic Supervisor", never fail to put me in mind of the game I used to play as a child. It is a great pity that there is no way of reciprocating these demands over the loudspeaker "Have you got Mr Chips, the Carpenter?" "No, but have you got Mr Wrench, the Engineer? *Thank* you, *and* Mrs Wrench, the Engineer's wife? *Thank* you"

After all, the normal working of the hospital could always carry on with coloured lights

* * *

Last week one of our elderly patients, after an operation for an upper femoral fracture, showed evidence of basal lung congestion, and his sputum was sent to the laboratory for examination The report came back "The carton contained matchsticks" Orthopædic surgeons have gained many a nickname in the past fifty years—carpenters and monumental masons among them Now I know why

Letters to the Editor

SURGERY OR RADIUM FOR CANCER?

SIR,—It is with regret that we notice that Professor McLaren and his colleagues (Jan 11) are using our recent communication as an occasion for reopening the old battle between radiotherapy and surgery in the treatment of cancer This battle may have been necessary once, but there can be little doubt that radiotherapy has become established as a therapeutic agent of immense value Today, therefore, there should be no prejudice or partisanship in the treatment of cancer—particularly carcinoma of the cervix, where it is of vital importance to the patient not to fall into the hands of either a surgical or radiation enthusiast, since each will use the method he knows best, and this may by no means coincide with the patient's best interest. One of the main functions of the joint clinic, the work of which has been reported, is to safeguard the patient against the risk of such misguided enthusiasm and ensure that she receive the most appropriate treatment, whether surgical or radiation, under the best conditions

Our object in reporting the work of the joint clinic was.

(1) To show that surgeon and radiotherapist can work in harmony as a team under ordinary hospital conditions
(2) To give some idea of the usefulness of such a clinic as reflected by numbers and types of case referred to it.
(3) To determine the advantages, if any, to the patient of the cooperative services thus made available.

To this end we compared the methods used and the results of treatment before and after 1944

It was not our aim or purpose to "do justice to surgery" or to "mention modern surgical results" There is already a wide literature on these themes and we would specially commend to Professor McLaren and his colleagues' attention Kottmeier's[1] analysis of surgical and radiation results, in which he shows convincingly that, with comparable clinical material, radiotherapy gives results equal to those claimed for surgery by Meigs and others Because we were conscious of our poor results in stage I (60·4% at 5 years), we undertook the "manœuvres" commented on by Professor McLaren—not, as he claims, to boost our radiotherapy cures to the detriment of surgery, but rather to boost our own morale It is always a cause for humiliation and self-searching if one's results are worse than those claimed by other workers The purpose of the discussion quoted by Professor McLaren was to show that under other and more fortunate conditions we, too, might have attained the 70% 5-year survival rates achieved by other workers which would have substantiated more firmly our statement that "It therefore seems that radiotherapy is not only undoubtedly the correct treatment in inoperable cases, but also usually the preferable treatment for operable cases" This statement forms the substance and flesh to be found on the seasonable but scrawny bird mentioned by Professor McLaren. Our statistical turkey was both home plucked and killed, since all the statistical tables were drawn up by one of us (C. A S) in the hope that our conclusions would not be befogged by the use of a multiplicity of incomprehensible statistical terms, usually much in evidence when unpalatable facts have to be obscured

We would summarise by repeating that our opinion based on our experience since 1944 is that in our hospital the results in stage-I cases (60·4%) submitted to radiation treatment compare well with those obtained when the Wertheim operation is performed (65·1%) In these circumstances we customarily recommend radiotherapy to our patients with carcinoma of the cervix (with the exceptions listed in our paper) To be able with confidence to offer a patient the opportunity of avoiding a major mutilating operation, we regard both as a gesture in the best tradition of medicine and as a happy reward for our labours over the past years

A DISTRICT MENTAL HEALTH SERVICE

Sir,—The Worthing Experiment, with an outpatient and domiciliary psychiatric service, described in your issue of Jan 4, is so obviously a step in the right direction that its success was assured We are particularly interested in the extensive use made of outpatient electroconvulsant therapy, since, for many years, we have regarded this procedure as the only method of substantially reducing the need for mental-hospital admissions

The Sheffield Mental Hospital, with its 2089 beds, has, since the last war, been responsible for a catchment-area population of a million people—a ratio of 2 beds per 1000, compared with 3–5 per 1000 for the country as a whole Admissions have of necessity been restricted to severely disturbed patients for whom outpatient treatment is inadvisable But it was fortunate that in 1942 outpatient electroconvulsant therapy first became practicable, and since then, the Sheffield Hospital has maintained an active unit which, in recent years, has provided up to 1000 treatments a year with satisfactory results in the moderately severe case of depression which could not be admitted because of shortage of beds A special treatment-session is reserved for geriatric patients

If it is estimated that the gross incidence of psychosis in the community is 9 per 1000, or 1800 cases in a 200,000 population, not more than a third of these will probably require inpatient treatment and not all in the same year

We therefore applaud the results achieved by Dr Carse and his colleagues, which amply support their plea for expansion of outpatient facilities in psychiatry It would seem that a unit of the Worthing type should be provided for each 200,000 population, and, until an effective substitute for modified electroconvulsant therapy can be found, each unit should be able to provide 30 to 40 treatments per week

Middlewood Hospital, Sheffield

F T Thorpe

Sir,—I have read with interest the report by Dr Carse and his colleagues on the Worthing experiment for a similar service has been in existence in most parts of the Manchester region for several years and its value is well recognised

In Bolton, for instance, a small psychiatric unit at a general hospital provides diagnostic and treatment clinics, day-hospital facilities, domiciliary service, and a psychiatric social club run jointly with the medical officer of health

Under present legislation, however, the success of a district service must depend on the cooperation of the local health authority and the support of the regional mental hospitals In Worthing the full cooperation of Graylingwell has apparently been enlisted, but it would be of interest to know how the public-health services have fitted into the scheme and what part the D A O s play The high degree of screening before admission to Graylingwell is certainly impressive

In some areas of our region it is felt that unless the local authority can provide more welfare and hostel accommodation the work of district mental health service will be hindered It is also important that a clear division should exist between the functions of a local psychiatric service and that of a large mental hospital With early outpatient treatment mental hospital beds will be needed mainly for the more severely disturbed and long-standing patients, many of them aged, and some hospitals—overcrowded as they are—may be reluctant to accept these "less promising" patients On the other hand, our experience shows that if a local service is accepted by the community, many patients are less willing to enter large mental hospitals

Finally, a clear system of priorities should be drawn up Once the facilities are available there is a constant increasing demand for the service, and the treatment centre may soon turn into a disposal centre for the increasing number of geriatric, "chronic sick" patients, not to mention additional work, brought by such agencies as the courts, probation service, and children's officers Unless the service is as well staffed as Worthing's seems to be, delays and disappointments will be inevitable

Royal Infirmary, Bolton

J T Leyberg

ANTIBIOTIC PROPHYLAXIS

Sir,—In reference to your valuable annotation (Jan 4), I should like to express my full agreement with your conclusion that antibiotics should not be used to prevent sepsis One risk is that of sensitisation This occasionally follows the prophylactic use of penicillin The result is disastrous if the antibiotic has, at any time later, to be used to combat actual sepsis

When arthritis is caused or aggravated by focal sepsis, the eradication of the focus may be essential to cure Here prophylaxis of some kind is necessary to prevent what otherwise might be a severe reaction Over many years I have never found prophylaxis with one of the sulphonamides to fail I have always prescribed sulphathiazole 1 g 4-hourly for 24 hours before and 48 hours after the operation Now that long-acting sulphonamides are available, 1 g daily for the same period has so far worked equally well

COMBINED BARIUM MEAL AND CHOLECYSTOGRAPHY

Sir,—Dr Robinson [1] evidently does not favour any technical variation which might interfere with the accuracy of cholecystography, but perhaps he expects too much from this examination There are claims that cholecystography is 96–98% accurate The confirmation of the radiological findings is based on surgery, which by inference must limit the criteria for pathology to non-function or the presence of gallstones Where cholecystography fails is in chronic cholecystitis in a gallbladder which still retains some function It might seem possible to assess function according to the density of the shadow, but there are so many factors—physiological and physical—which influence contrast that such an examination would be almost valueless When the demands of a large general hospital can be eased by a combination of examinations it is reasonable to adopt this technique, and we cannot agree with Dr Robinson that the fine detail of the examination is sacrificed Indeed we have made some striking films of small calculi

In reply to Mr Forty,[2] we certainly agree that calculi may exist without producing symptoms, but this also applies to a non-functioning gallbladder It is in these patients that the combined technique is so useful in bringing to light associated lesions in the gastrointestinal tract which may account for some of the 30% of postoperative failures discussed by Ogilvie

In a recent series of 2000 patients examined by this combined technique, 193 (9 7%) had pathological gallbladders 100 of ese showed no evidence of function, and 93 functioned but ontained opaque or non-opaque calculi

MANIPULATION FOR BACKACHE

SIR,—As Mr Bremner (Jan 4) infers, a great deal of onsense is talked about manipulation It is therefore a ity that his painstaking work is invalidated by the com- lete absence of control cases in his series When dealing ith something as personal as low-back pain it is impos- ible to eschew patients' subjective impressions, but I ind it difficult to believe that so few of his cases exhibited bnormal physical signs Thus instead of a useful tatistical stick with which pro- or anti-manipulation xtremists might have been beaten, we are left with just ne more straw composed of clinical impressions

One must also deprecate Mr Bremner's failure accurately to define on *clinical* grounds what is meant by "lumbosacral strain" Even when accompanied by a half-hearted apology, usage is no excuse for the use of such a term which, though certainly "concise", is meaningless as he himself demonstrates This does nothing to further the introduction of order into the chaos of dogma and empiricism which surrounds the subject of backache and its treatment

Finally, it should not prove very difficult to explain the incidence of backache in the ratio of 1 8 females to 1 male in Mr Bremner's series A careful analysis of how the average day is spent would probably show that most of the 116 married women were subjected to more "externally applied strain" than most of the 84 males The average modern housewife does not apply many sudden, violent, and dramatic strains to her back, but the sum of the stresses imposed by household chores, children, and not infrequently a whole- or part-time job as well, is immense, as can be testified by any husband who has tried to cope alone for a few days

St Thomas Hospital,
London, S E 1

D R L NEWTON

SIR,—Being "osteopathically" inclined, and seeing many patients with backache, I was interested and pleased to read Mr Bremner's article (Jan 4) I should like to point out that we osteopathically inclined have never claimed a 100% cure-rate, but we do claim a high proportion of good results I was particularly pleased to see such good results even with non-specific "orthopædic" manipulation

If we use greater care in diagnosis instead of grouping all patients together under this vague heading of "lumbosacral strain", and if specific treatment is given to each type of low backache, then the results should be still better than those quoted by Mr Bremner This is in fact so

If we lumped together all patients with indigestion and treated them with alkaline powders, there would be some good results, but if they were analysed carefully and treatment prescribed accordingly, there would certainly be a higher percentage of good results

Differential diagnosis of low backache is difficult, but it is a mistake to say that "physical signs are few or absent" The points to look for are the mobility range of both the area and the individual joints, the tenderness in interspinous ligaments, the tension in the erector spinæ muscles, the relative position of one vertebra to the next, the kyphoses, lordoses, and scolioses, and finally changes in the erect radiographs and mobility films

The first and fundamental differential point is to distinguish between hypermobility and hypomobility To manipulate joints which are already hypermobile is likely to give bad results The differentiation can be made by palpation and mobility radiographs

If there is hypomobility but no lesion or root signs, manipulation is almost always indicated The next point is to locate the site of restriction so that the manipulation can be applied to the faulty joint rather than to the whole lumbar spine It is better, and easier, to achieve a specific manipulation without an anæsthetic than with one

If hypermobility is found, a corset and strengthening exercises are indicated, or injections of sclerosing fluid into the interspinous ligaments [1]

Mr Bremner found that in 3 6% of patients the condition was aggravated by manipulation These, and some of those not improved, probably had the hypermobility type of low backache where the ligaments are overstretched already I realise that his series aimed specifically at determining the benefit or otherwise of one manipulation, and to that end the experiment is to be commended But if in private practice one were to make 3 6% of one's patients worse, it would soon ruin the practice A bad reputation travels faster than a good reputation

London, W 1

ALAN STODDARD

SEX REVERSAL

SIR,—Dr Ashley and Dr Jones (Jan 11) are to be congratulated on their critical discussion, which helps to clarify the position of their lucidly presented case in the increasing complexity of intersex states I have recently seen three unusual examples of gonadal dysgenesis, all with male nuclear sex

The first patient, an otherwise classical example of Turner's syndrome with short stature and webbing of the neck, has apparently menstruated for seven years, the second is a colour-blind dwarf whose father has normal colour-vision, and the third is a tall eunuchoid female with no stigmata of Turner's syndrome The third case, similar to those reported by Swyer,[2] and different from that of Ashley and Jones in that the leucocytes show typical male morphology, is probably a variant of gonadal dysgenesis,[3 4] and helps to stress that reclassification is required

You rightly say, Sir, that there is urgent need for a new terminology, and though your discussion is mainly concerned with examples of sex reversal, it is very important that any classification must also include cases of chromatin-positive Turner's syndrome and of chromatin-negative Klinefelter's syndrome At the symposium on nuclear sex, a committee was appointed to consider the question of nomenclature, but your plea of urgency suggests that the matter might now be discussed profitably in your columns

In the many types of pseudohermaphroditism, which include testicular feminisation and congenital adrenal virilism, gonadal sex and nuclear sex are in conformity and the defect is apparently not primarily due to dysgenetic gonadal development. In other intersex states, however, gonadal involvement does appear to be of primary importance and the corticomedullary balance theory of gonadal differentiation seems to be a suitable basis for classification and nomenclature Such a scheme, which can be conveniently tabulated and is self-explanatory, is offered below for comment Some of the least ambiguous of the old names, shown in parentheses, might continue to be used, but a name is required for the case recorded by Ashley and Jones, and a new name for the Klinefelter syndrome and its modifications is long overdue

[4] Swyer, G I M *ibid* p 1421

CLASSIFICATION AND NOMENCLATURE OF INTERSEX STATES

I Both Gonadal Components Dysgenetic
- (1) Underdevelopment
  - (*a*) Complete failure Corticomedullary agenesis (gonadal agenesis)
  - (*b*) Partial failure Hypoplastic corticomedullary dysgenesis (gonadal dysgenesis)
- (2) Overdevelopment of the component which should have been suppressed with collateral development of the other components Hyperplastic corticomedullary dysgenesis (true hermaphroditism)

II One Gonadal Component Dysgenetic (with non-development or suppression of the other component)
- A *Gonadal medulla dysgenetic*
  - 1 Overdevelopment Hyperplastic medullary dysgenesis (Chromatin-positive Klinefelter's syndrome)
  - 2 Underdevelopment Hypoplastic medullary dysgenesis (Chromatin-negative Klinefelter's syndrome)
- B *Gonadal cortex dysgenetic*
  - 1 Overdevelopment Hyperplastic cortical dysgenesis (case of Ashley and Jones)
  - 2 *Underdevelopment Hypoplastic cortical dysgenesis* (recognition awaited, but perhaps the case described by Hoffenberg et al[5] would fit)

Glasgow JOHN S S STEWART

GALLSTONES AND THE SURGEON

SIR,—In your leading article of Dec 21 no mention is made of intraoperative cholangiography The indications for exploration of the common duct given by Ogilvie[6] are rather vague, and in fact they may be misleading In the majority of cases intraoperative cholangiography reveals unequivocally the presence of stones or papillitis

University Hospital,
Basle, Switzerland RUDOLF NISSEN

A THYROID ASSOCIATION

SIR,—The suggestion from Professor Fraser and his colleagues (Jan 11) for forming a Thyroid Association of Great Britain deserves the very strong and full support of all those interested in thyroid disease

Such an association could be greatly strengthened by extending membership to Ireland and the Commonwealth, where valuable scientific contributions are continually being made

A similar association in Europe would then work in close harmony with this body and the well-established American Goiter Association and their related endocrine societies

Regional advance in the understanding of thyroid and allied diseases could be stimulated and canalised by each of these bodies and periodically coordinated by more frequent international meetings

No international goitre meeting has been held previously in Great Britain The last such gathering took place in Washington in 1938 With to-day's easy and rapid air travel, these long intervals seem out of date in such a swiftly advancing field of research

As I said in your columns[7] and elsewhere[8] in advocating an international meeting on thyroid nomenclature, much potentially valuable work is being invalidated by uncoordinated methods of investigation and procedure This is particularly so where advances in thyroid research have recently invaded so many fields and disciplines

The flourishing American Goiter Association, at whose meetings we have been made most welcome, is an example of the great good such a body can achieve The invaluable active support of the Royal Colleges of Surgeons and Physicians would also give a strong impetus to the creation and growth of a similar organisation in our midst

London, W 1 T LEVITT

RADIATION AND LEUKÆMIA

SIR,—The data reported in our study of leukæmia in patients irradiated for ankylosing spondylitis (to which Dr Pochin refers in his letter of Jan 4) were collected at the request of the Medical Research Council, in the hope that they would provide some indication of the nature of the relationship between the dose of radiation and the resulting incidence of the disease Although it was realised that no direct information would be obtained about the effect of doses as low as those commonly given in diagnostic radiology, it was hoped that it might be possible to estimate their effect by extrapolation from the results at higher levels of dose It transpired, however, that quite a large number of patients were given radiation to areas other than the spine and sacroiliac joints, and for these patients it proved impracticable to estimate the size of the relevant dose (assumed to be the mean dose to the active bone-marrow) Our principal analysis was, therefore, limited to the group of patients whose treatment was directed solely to the spinal axis and for whom we obtained reasonably accurate data on the distribution of radiation dose within the spinal marrow

In this group 18 patients developed leukæmia The mean spinal-marrow dose received by these patients varied between 315r and 2195r, and it is clear that the data could not provide firm evidence of the quantitative effects at really low levels of dose On the other hand, the data gave no positive indication of the existence of a threshold below which no effect was produced, and the incidence of leukæmia observed in the general population (presumed to have had no therapeutic dose) was close to that estimated for zero dose from the observed incidence at other levels We therefore suggested, as a working hypothesis, that there was no threshold dose for the induction of the disease and included the point representing the estimated incidence for zero dose in the data from which the quantitative relationship between dose and incidence was calculated

If (as Dr Pochin suggests) the point for zero dose is omitted, and a regression line calculated from the incidence-rates for spondylitic patients alone (standardised for age and weighted according to their reliability) we obtain the equation $y=0\ 00634x-0\ 34$, where y is the annual incidence per 10,000 men at risk, and x is the mean spiral-marrow dose in röntgens Hence the estimate of therapeutic dose which would correspond to zero incidence is 54r

In view of the paucity of data the error of this estimate is liable to be very large If the probable limits of the regression line are calculated by a method similar to that derived by Irwin,[1] it is found that the 95% confidence limits for the "true value" of the dose corresponding to zero incidence are −1700r and +400r In other words, the threshold value may be zero or anywhere between zero and 400r This calculation is made on the assumption that all the cases of leukæmia in the treated series were due to irradiation If, however, some of the cases were due to other causes, the estimate of the probable threshold dose would be slightly higher If no case of leukæmia occurring in the general population was due to irradiation, the estimated threshold dose would correspond to an incidence in a sample of the general population of the same age-distribution as that in the population of spondylitics (i e , 0 49 cases annually per 10,000 men) and would be about 130r therapeutic dose with a likely upper limit of about 460r

All these doses, it must be stressed, are mean doses to the spinal marrow If it is assumed that there is a linear relationship between dose and incidence and that there is no threshold for the induction of the disease, it is possible to convert a mean spinal dose into a mean dose to the whole active marrow In our report this was done by dividing by a factor of 2 to 3, since it was thought that the spinal marrow constituted between a half and a third of the total active marrow If, however, it is postulated that a threshold exists, such a conversion is impossible, in this case, there is no real justification for using a mean spinal dose as the measure of effective dose in the study of the dose/response relationship, and it might be thought preferable to relate the incidence of leukæmia to the maximum dose received at a point in the marrow Such an analysis was made during the course of our investigations, and the results were reported in Appendix B of the Medical Research Council's report on *The Hazards to Man of Nuclear and Allied Radiations* This analysis also provided estimates of incidence which appeared to be proportional to the dose and certainly gave no indication of the existence of a threshold For reasons which are discussed in our report, however, we felt that this method of analysis might introduce a systematic bias into the results, and we preferred to use the mean spinal marrow dose as the best estimate of the effective dose

---

[5] Hoffenberg, H , Jackson, W P U , Muller, W H *J clin Endocrin* 1957, 17, 902
[6] Ogilvie, W H *Ann R Coll Surg Engl* 1957, 21, 319

[1] Irwin, J O *J Hyg , Camb* 1943, 43, 121

In conclusion it is clear that we continue to be ignorant of whether or not a threshold dose exists One way in which the problem may be solved is by undertaking further epidemiological studies, comparable to the survey of irradiated cases of ankylosing spondylitis To plan such surveys, however, it is necessary to proceed on the basis of some hypothesis The data obtained in our study led us to the conclusion that the most reasonable hypothesis to work with was that no threshold existed and we see no reason to modify it We hope that no-one will mistake the delineation of a working hypothesis for a statement of established fact

A THEORY OF NERVE DEAFNESS

SIR,—The hypothesis of Mr Gregory and Miss Wallace (Jan 11) concerning causes of impairment of hearing in what they call " nerve " deafness is interesting, but it seems to me that they formulated this view with only limited background information about the various types of non-conductive impairment of hearing

They mention that the terminology of non-conductive deafness is confusing, but surprisingly they themselves made a mistake leading to further confusion They call an impairment involving predominantly high frequencies " presbyacusia " This is, however, a term used for one definite type of deafness, clinically well known—that is, old-age deafness Old-age deafness has some distinct peculiarities, and therefore to call all types of high-note impairment by this term is confusing Moreover, they call this type of " nerve " deafness, characterised by a predominantly high-note loss, the typical one, and imply that it is numerically the most important, allowing certain generalisations This is incorrect There are several types of deafness (not conductive) which do not have this " typical " predominantly high-frequency loss Even in Ménière's disease, in the more developed cases, the audiogram is more often " flat "—that is, showing a more or less uniform loss for all frequencies Another type of non-conductive deafness in which the lesion is also in the end-organ (that is, deafness from maternal rubella) has also this characteristic " flat " audiogram without a predominantly high-note loss There are some indications of recruitment also in these cases of deafness from maternal rubella

Further, there are types of hearing loss, undoubtedly non-conductive, in which not only is there no predominantly high-note loss, but the hearing is distinctly *better* for the high notes We are at present studying these types, and I have not only numerous audiometric records available but also *histological* evidence that the lesion is undoubtedly in the end organ—namely, in the organ of Corti

In all these cases, of course, there is a considerable reduction in channel capacity of the communication system, caused by some disturbance in the end-organ, but no reduction of high-note discrimination as a result of it This is against the suggestion of Mr Gregory and Miss Wallace that reduction in channel capacity by an end-organ lesion leads to an impairment of high-frequency discrimination

I must also mention that not only is there often a tendency in " nerve " deafness for an inner-ear lesion to produce a uniform loss for all frequencies but also a typical predominantly high-frequency type of deafness is often caused by a lesion which is *not* in the end-organ but higher up in the auditory pathway A good example is deafness from hæmolytic disease of the newborn We are studying another type in which there is also a symmetrical loss predominantly for the higher frequencies, and in which we have good reasons to believe that the location of the damage is not in the end-organ but at certain levels in the auditory pathway We hope, to report these findings soon, and also to give a theoretical explanation why the high frequencies are affected

I am not saying this to dispute the possibility that, in some cases, random neural noise, affecting unfavourably the noise-to-signal ratio, may not impair discrimination in the high-frequency range, but when a general hypothesis is formulated at this early stage of study, it is dangerous to disregard certain factors which contradict it from the beginning This may lead to a false theory

L FISCH

LABORATORY DIAGNOSIS OF CONGENITAL GALACTOSÆMIA AT BIRTH

SIR,—In the article by Dr Schwarz and his colleagues describing the laboratory diagnosis of congenital galactosæmia at birth (Jan 4), reference is made to a milk-free diet described by Holzel in 1954 [1] In his original article Holzel states this diet to be " a modification of Moll's pudding, consisting of Farex, eggs and sugar in appropriate dilutions "

May I draw your attention to the fact that the present preparation of ' Farex ' (Glaxo) contains separated milk powder ? This has been added to the product since September, 1954, so that farex now contains 5% separated milk powder and 2 5% lactose In view of the varying tolerance to lactose exhibited in those cases of galactosæmia reported in the literature, it seems advisable that those who may need to use farex should be made aware of its present composition

St. Bartholomew's Hospital,
London, E C 1

MARY FURNIVALL
Chief Dietitian

PREGNANCY AND COARCTATION OF THE AORTA

SIR,—I have read with interest the article by Dr Goodwin (Jan 4) on the risks of pregnancy in coarctation of the aorta, in which he analyses 13 cases of his own and 123 cases previously published He concludes that the hazards of pregnancy in unrelieved coarctation depend largely on the presence or absence of added cardiovascular lesions, especially those of the aortic valve As prophylactic resection of the coarctation is being increasingly performed in young persons, the prognosis of coarctation treated conservatively will become harder to assess I wish therefore to report a case seen in general practice

---

[1] Holzel, A *Med ill* 1954, 8, 44

A woman, aged 37, has coarctation and pulmonary tuberculosis When she was 19, she was referred to a tuberculosis officer for his opinion, and coarctation was first diagnosed by the radiologist from the well-marked notches on the ribs Full assessment at that time showed no hypertension (blood-pressure in arms 130/80 mm Hg), and no evidence of aortic incompetence or other cardiac lesion The electrocardiogram was normal Subsequently she married, and had four normal pregnancies terminating in one forceps and three normal deliveries Her last pregnancy was at the age of 35, and she was sterilised during the puerperium. Although her blood-pressure has been labile, she did not develop hypertension during any of her pregnancies, and only during the past year has her blood-pressure started to rise Her coarctation remains remarkably symptom-free, and she leads the full life of a busy housewife She has moderate dyspnœa on exertion, which is largely a sequel of pulmonary tuberculosis

This patient's history confirms the fact that careful conservative management of four pregnancies may be undertaken without deleterious effect when coarctation is uncomplicated by additional cardiac disease

Bungay, Suffolk W M JORDAN

A FUNCTIONAL NECESSITY

SIR,—I was much interested by Professor Platt's letter[1] on the subject of consultant appointments, and I heartily agree with him that it would be wrong to create a new subconsultant grade However, a prerequisite to proper staffing is a knowledge of the needs of the individual regions, and such knowledge seems peculiarly hard to acquire

When I was a member of the North West Metropolitan Regional Hospital Board's medical committee, it took me some months to get the officials even to allow a discussion on this subject When we asked for the report of the Ministry of Health working party which had reviewed the consultant establishments of the region, we were informed that their report had never been published In September of last year I once again endeavoured to ventilate this subject in the medical committee of the board A request for details of the existing consultant and S H M O establishment in the region, and for information about all requests for additional consultant appointments, was met with the written reply

> "The information requested would be most difficult to assemble and would involve a close examination of all the Board's records on medical staffing since 1948 Quite apart from this the Board's staff is so sorely pressed at the present time that to embark on this project would be quite impossible "

When regional-board officials and others show such scant interest in a problem of major importance, and when serious impediments are placed in the way of medical committee members who endeavour to secure factual information, it would seem high time for the Joint Consultants Committee to urge a nation-wide review of consultant establishments I would further suggest that the various regional consultant and specialist committees should press their respective regional boards so as to ensure that the necessary information is made available Once our professional committees have the facts it may be easier to overcome the deadly inertia and official buck-passing of the present time

Radlett, Herts REGINALD S MURLEY

SIR,—The logic of Mr Brearley's letter of Jan 4 is incontestible The solution to the senior-registrar problem now and in the future lies in the appointment of more consultants, especially in general medicine and general surgery However, the Ministry are unlikely to make any movements in this direction without being convinced that the hospital consultant service is in imminent danger of breakdown Unfortunately, the undoubted shortage of consultants has been obscured since the inception of the service by the fact that most consultants have been working overtime This habit, which would be condemned immediately by any trade union, seems to be inseparable from a vocational profession Ironically enough, the Minister is already supplying the remedy in the form of economic pressure, resulting from the steady decrease in the real income of hospital employees No longer will these doctors be able to subsidise the health service on the scale which has applied in the past They will be too busy attending to the chores, the repairs, and the decorations at home where adequate help can no longer be afforded Waiting-lists will grow and the problems in question will be solved much more quickly than they would ever be as a result of the negotiations which are *proceeding interminably*

Liverpool NORMAN GIBBON

SYRINGES CLEAN OR STERILE?

SIR,—Your annotation of Jan 4, drawing attention to the Nuffield Provincial Hospital Trust's book on the planning and organisation of central syringe-sterilisation services, is most welcome, and I hope will further accelerate the spread of such services throughout our hospitals In terms of economy and preventive medicine, central syringe sterilisation should appeal to lay and medical members of boards of management alike

It seems timely, too, to consider sterilisation of syringes in public health clinics and general practice, especially on account of the impending inoculation of adults against poliomyelitis

Mass inoculation campaigns in children, using one syringe, and a different, recently sterilised, needle for each child, have been happily free from the spread of syringe-transmitted hepatitis In adults, however, such substandard technique—excused by some on grounds of practicability—seems likely, in the light of experience, to prove dangerous There is ample proof in the literature that irrespective, of the type of injection, epidemics of hepatitis are likely to occur in clinic populations where *each patient is not served with a sterile* syringe and needle Hepatitis is not generally listed by public health authorities as a notifiable disease, and since its incubation period is long, much harm may be done before the dangers are fully appreciated

Public health authorities and general practitioners, no less, therefore, than hospitals, would do well to reconsider their sterilisation arrangements, not only in terms of preventive medicine, but also perhaps, since the consequences of using contaminated equipment are well established, from the medicolegal aspect also

Stockport R S MORTON

SIR,—Your annotation of Jan 4 makes no mention of the problems of syringe sterilisation in general practice

I have obtained a supply of 2 ml Luer lock syringes wit number-17 hypodermic needles mounted and protected by metal needle guard These are packed in a cylindric screw-capped metal container, with a small cotton-wo plug

The containers are autoclaved for me at my local hosp and I imagine that most hospitals would cooperate w family doctors in this way

---

[1] *Lancet*, 1957, ii, 1336

A safe sterile syringe in one's coat pocket car or visiting bag, ready for immediate use, with a sterile plug of cotton-wool for skin preparation, is particularly useful when answering an emergency call

London, S.E.26. R N JACKSON

TUBERCULOSIS IN THE SCHOOL

SIR,—Many will agree with the opening and closing sentiments of your annotation [1] Certainly the tuberculin test is a very useful tool in investigating the epidemiology of tuberculosis among schoolchildren. Not only does a positive reaction indicate which children need to be examined more carefully and followed, but the identification of those who have been in contact with an infectious case of tuberculosis makes it possible to identify the source case among their current associates Moss and Fairweather [2] have again demonstrated the great value of this approach to the prevention of tuberculosis

At the same time, the Clitheroe experience clearly points up a serious disadvantage of B C G vaccination Aside from the question of the logic of vaccinating the children who were still uninfected after the source cases had been removed, the positive tuberculin reactions engendered by B C G will make a similar surveillance impossible in the future Is not B C.G vaccination under these circumstances rather like killing the goose that laid the golden eggs?

HÆMORRHAGE IN LIVER DISEASE TREATMENT WITH SEROTONIN

SIR,—We have had the opportunity of testing serotonin in three cases of hæmorrhage appearing in the course of severe liver disease

One patient had juvenile cirrhosis (postmalarial?) with hypersplenism (leucopenia, thrombocytopenia), hæmorrhages and purpura, treated by splenectomy, two had severe and protracted epidemic hepatitis (post-transfusional in one) with a severe hæmorrhagic state characterised by spontaneous ecchymosis

To estimate the efficiency of serotonin the following tests were carried out before and after the beginning of the treatment with serotonin

The bleeding-time, the coagulation-time of the venous blood at 37°C (Lee-White), the Rumpel-Leede test after venous stasis at over-diastolic arterial pressure for 5 min, the clot retraction (serum expressed per 5 ml blood after 60 minutes in the incubator), and the platelet-count.

Serotonin 1–2 vials of 5 mg intramuscularly, was given daily for a few days. It was well tolerated and produced no local or general reactions such as were seen after intravenous administration (e.g, tachycardia, hypertension and dyspnœa) Improvement in the hæmorrhagic state was indicated by cessation of bleeding in the skin and alimentary-tract hæmorrhages The bleeding-time diminished in all three cases (see table) The coagulation-time improved the Rumpel-Leede sign became negative, and the clot retraction improved, but the number of platelets remained at the same low level

From our data it seems that serotonin acts especially on the capillary resistance and clot-retraction without influencing, in the doses used, the number of platelets.

The serotonin was kindly supplied by Messrs Hoffmann-La Roche

Hospital of Infectious Diseases,
Colentina Bucharest, Rumania.

NEUMAN MAYR
P TEODORESCU

EFFECT OF SEROTONIN ON HÆMORRHAGIC STATE

THE DIFFICULT KNEE

SIR,—May I congratulate you on your annotation of Dec 14[3] I should however, like to discuss several points

(1) A knowledge of the mechanism of injury is essential.

(*a*) A direct injury can cause contusion and bruising of the soft-tissue structures such as the infrapatellar pad of fat, alar folds, synovial membranes, and menisci as well as the articular cartilages and bones of the tibia, femur, and patella Unless these cases are treated by immediate active methods, including rest from all forms of strain, and appropriate graduated exercises, complications tend to develop which include an unstable knee, a stiff knee, articular cartilage erosion, chondromalacia patellæ, and early joint degeneration It would seem that too many cases with a history of direct injury are subjected to menisectomy far too soon The effects of contusion and bruising, if allowed to become chronic, may take many months of treatment to overcome especially if the case has been neglected at the beginning

(*b*) The components of an indirect injury must be clarified Was it a purely abduction strain or was there an element of rotation and flexion as well? A hyperextension injury may contuse the infrapatellar pad of fat and involve the structures in relation to the tibial spine as well as stretching or tearing the posterior capsular structures It should be realised that in an indirect injury the structures on one side of the joint are stretched or torn, whereas those on the opposite side may suffer direct injury and be contused and bruised

(2) Before operation the stability of the joint must be assessed One of the menisci may be torn, but the prognosis is entirely different when there is a stable knee and when there is cruciate or lateral ligament laxity The knee may give way on occasions without true locking and McMurray's tests may be negative, but often, although flexion may appear to be full, a rubbery elastic feeling can be elicited and there is a distinct difference in the feel of the two sides The patient

---

[1] *Lancet*, 1957, ii, 784
[2] Moss, P S., Fairweather, J H *Brit J Tuberc* 1957, 51, 258

appreciates this difference as he can do a full-knees bend on the good side but not on the affected one

(3) At operation the femoral and tibial articular cartilages must be observed and the patellar one as well if necessary These findings are important in regulating the tempo of convalescence and rehabilitation The stability of the ligaments is again assessed under anaesthesia and direct vision A recent case illustrates this point

A young rugger player aged 17 showed signs of a torn medial meniscus of the right knee At operation there was no evidence of articular-cartilage damage and the ligaments were normal He made a quick convalescence and had no trouble with this knee Three years later he injured his left knee while parachuting and the knee continued to give way on several occasions At operation, apart from the tear of the medial meniscus there was evidence of early erosion of the articular cartilage on the medial condyle This knee now is returning to full function slowly

In a case of this sort it is essential not to force strenuous activity

(4) Chondromalacia patellæ is certainly a common sequel to any injury of the knee-joint, but it often occurs in childhood and adolescence from no apparent cause These cases can often be kept in circulation by modifying one of their activities such as avoiding P T and Corps work at school but allowing cricket and even football They should wear sponge-rubber heels to avoid jarring and carry out conscientious daily home treatment and physiotherapy, first as a course and later once a week Without treatment the condition progresses and may require operation Occasionally, in spite of great care operation may be inevitable

(5) Every case of injury to the knee-joint, especially a joint in which menisectomy has been performed, is a potential case of osteoarthritis The early physical signs of this condition are articular cartilage rolling and synovial thickening Sometimes in these latter cases even radiographs show a normal joint, but this constitutes the pre-X-ray phase of osteoarthritis and is reversible with appropriate treatment Removal of a meniscus may be necessary in a middle-aged man associated with early osteoarthritis but it must be remembered that the operation itself gives three weeks' rest from strain and in the more advanced osteoarthritis simple removal of the meniscus does not make them symptom-free The patient is warned of the likelihood of osteoarthritis and if he will only persist with regular home treatment indefinitely he can delay the onset This claim will be open to criticism but many patients in whom osteoarthritis has developed have been helped by home treatment and courses of physiotherapy and lose their physical signs and symptoms If a claim for a cure for osteoarthritis had been made 20 years ago the doctor would be considered a charlatan, but since it has been proved that articular cartilage can regenerate patients showing early osteoarthritis can themselves become symptom-free It is essential in these cases, however, for the patient to continue home treatment indefinitely

(7) In about 2–5% of cases in which the diagnosis is difficult and in doubt, I have always found that arthrograms, as carried out by Somerville, have supplied the answer in almost every case As performed by him this is a method without danger

(8) Few textbooks draw attention to the secondary effects on the joint above and below the injury Such muscles as the hamstring and adductor magnus affect the movements of the hip as well as the knee, and in knee injuries they tend to contract and shorten This also applies to the calf muscles and their effect on the movements of the ankle-joint Full extensibility and flexibility of the muscles must be restored with full movements of both ankle and hip as well as the knee before the patient can expect to have a knee which is 100% No patient with a knee injury should be labelled "functional" until full movement has been obtained in the hip, knee, and ankle joints as well as restoration of full muscle power To obtain this the knee may have to be subjected to a series of controlled manipulations under thiopentone, as well as long courses of physiotherapy including gentle manipulations

London, W 1 **W E Tucker**

ENZYME TESTS FOR GLUCOSE

Sir,—May I support Dr Miller's view (Jan 11) of the reliability of the enzyme tests ('Clinistix' and 'Testape') as a means of detecting, but not measuring, urine-glucose?

The 11% of discrepancies found by Tunbridge et al,[1] and quoted in *Prescribers' Notes* (May, 1957), arises from the assumption that a negative reaction with 'Clinitest', or other copper-reduction tests, means that glucose is absent, whereas the true position is that the enzyme tests can detect a lower level of glycosuria than can clinitest, though the clinical significance of such a trace of glucose may be slight

Reducing sugars other than glucose are not, of course, detected by the enzyme tests, but I have encountered only two substances which give false-positive reactions—namely, hydrogen peroxide and hypochlorites The first is largely of theoretical interest, but many household and laboratory cleansers contain hypochlorites, and false positive reactions can arise from gross contamination of urine containers

I should be very interested to hear of a positive reaction in uncontaminated urine, where glucose was proved to be absent —e g, by paper chromatography

The specificity of glucose oxidase is not in dispute, and false-positive reactions are more likely to arise from substances capable of oxidising *o*-tolidine to give the blue pigment So far as I am aware, no such substance has been found in urine

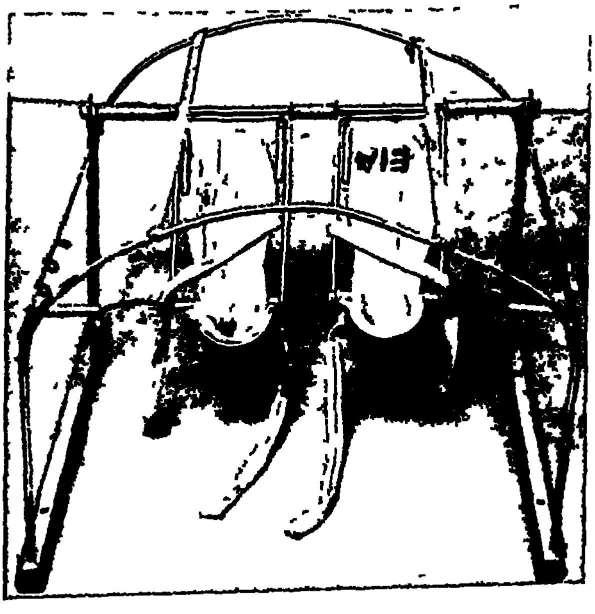
Royal Infirmary, Edinburgh
Samuel C Frazer

POSTOPERATIVE VENOUS THROMBOSIS

Sir,—Your leader of Nov 30 and Dr Rivlin's letter (Dec 21) draw attention to the need for active movement in the lower limbs in the prevention of venous thrombosis in recumbent patients, and as a necessary supplement to anticoagulants in the treatment of established venous thrombosis

Many patients, however, are in need of exercise, but unfit to get up Encouragement to move about in the bed, or to keep the lower limbs moving, is often insufficient to ensure adequate venous return, and many are naturally apprehensive lest they injure themselves or their operation wounds There are special



---

[1] Tunbridge, R E, Paley, R G, Coulson, D *Brit med J* 1956, ii, 588

indications for actively exercising the legs in thrombophlebitis, and where venous thrombosis is feared after operation or during long recumbency For this reason a leg exerciser was devised, the objects of which were

To allow movement against resistance, both at the ankles and knees, which the patient could continue to perform as required and without undue fatigue.

To provide suitably padded pedals without danger of damage from friction or pressure over the skin of the heels or elsewhere.

To make the apparatus portable and easily accommodated in a hospital bed beneath the bedclothes

The accompanying illustration shows the apparatus made for this purpose by the engineers' department at the Queen Elizabeth Hospital, Birmingham It was adapted from a standard bed-cradle, into which were built brackets to hold pedals suspended from above, hinged at suitable points, and attached to the cradle by springs, thus providing resistance to both ankle and knee movements Hooks were so fitted that the sites of attachment of the springs to the cradle itself could be changed, and their tension readily adjusted to suit the requirements of each patient.

This apparatus has proved acceptable to patients, comfortable in use, and of value in retaining muscle tone in recumbent patients It should be helpful in preventing postoperative and other thrombophlebitic complications, and, in conjunction with anticoagulants, accelerating the resolution of œdema of the legs in established cases of venous thrombosis

I am indebted to Mr T F Dee, clinical photographer at the Queen Elizabeth Hospital, Birmingham, for the illustration, and to the engineering departments of the Queen Elizabeth and General Hospitals, Birmingham, for making the apparatus

Edgbaston, Birmingham. G E OWEN WILLIAMS

SANATORIA BEDS

SIR,—In matters of medical treatment the pendulum of fashion is apt to swing too far and too fast Dr Beresford's letter (Jan. 4) is an example of this He can see no good in the larger sanatoria, where education of the patient, said by him to have little scientific basis, is still thought to be an essential part of treatment and rehabilitation Furthermore, such treatment is said to breed hypochondriacs Nothing could be further from the truth Considerable experience on both sides of the blanket has convinced me that the valetudinarian is a product of long domiciliary treatment The patient idling around at home loses a sense of purpose much more rapidly than the sanatorium inmate whose graduated activity is leading steadily on towards return to normal life and employment

Reading Dr Beresford's letter, one would think that the large sanatorium had nothing to offer except rules and regulations What about laboratory facilities, resident staff, and surgical units? It seems to me that many people have reached the erroneous conclusion that the treatment of pulmonary tuberculosis has become just too easy since the discovery of streptomycin—a conclusion which may be responsible for the increasing number of patients admitted to sanatoria harbouring resistant strains of the tubercle bacillus I have the good fortune to work in an area where adequate admission to hospital is still the treatment of choice in newly discovered cases, and as a result the proportion of resistant strains is below average It is still high enough to make the use of all three standard drugs advisable at least until the sensitivity of the strains are known 60% of our tuberculous admissions are still open cases

Presumably I am one of the "interested parties" who are striving to maintain the larger sanatoria But what of Dr Beresford? Are there also interested parties striving to maintain the smaller units?

Cheshire Joint Sanatorium,
Market Drayton, Salop A CLARK PENMAN

[illegible]

[illegible]

P.C., [illegible]

THOUGH [illegible] Ministers of [illegible] which he [illegible] background [illegible] politics Nevertheless [illegible] hall was firmly based [illegible] principles, and [illegible] health and [illegible] also a real [illegible] was at that time, [illegible]

He was born in [illegible] Lanark. From Glasgow [illegible]

Universal Pictorial Press

[illegible] recognised the value of [illegible] a contemporary recalls, "[illegible] but Elliot's arrows were [illegible] argument, he was a formidable [illegible] take with equal grace and [illegible] 1910 and M.B in 1913 he was [illegible] Royal Infirmary before he [illegible] 1914 to 1918 he served in France [illegible] Cross and bar

Almost immediately after [illegible] elected Unionist M P for Lanark [illegible] medicine began to slacken. For [illegible] public-health staff of a London [illegible] research on animal nutrition [illegible] (when John Boyd Orr was the [illegible] in 1923 But thenceforward the [illegible] in politics He held junior offices [illegible] ment, the Ministry of Health, and [illegible] ing the '20s In 1932 he became [illegible] in 1936 Secretary of State for Scotland [illegible] Minister of Health The quality of [illegible] bench and on the back benches of the House [illegible] are shown by these tributes from a Civil Servant and [illegible] a fellow M P

Elliot's stay as Minister of Health [illegible] left in 1940 when the plans for the [illegible] Services and evacuation were beginning [illegible] and when his experience and driving [illegible] enhanced his reputation as an administrator [illegible] of Health come and go, and Elliot bore his disappointment with equanimity

On visits of inspection in England and Wales he was a delightful companion, keenly interested in everything and enjoying temporary release from his desk He worked hard, too hard we thought sometimes, for he never spared himself He took a special interest in nutrition, fostered by his experience as Minister of Agriculture, and I recall many talks with him and Lord Boyd Orr New knowledge of the subject, partly through Elliot's influence, was embodied in the Government's rationing scheme

It is difficult to realise that he has gone from us That tall figure so full of vitality, enthusiasm, and brilliance, that fluent speech adorned with Scottish accent, wit, and humour, that desire to serve his country which led him to arduous missions abroad, and also to represent his Sovereign as Lord High Commissioner to the General Assembly of the Church of Scotland—all these seemed so essential a part of the national life

A S M

To most of us who were his contemporaries in Parliament, Walter Elliot will be remembered rather as an influential back-bencher than as a Minister and scarcely at all as a doctor "Colonel Elliot" frequently, "Mr Elliot" often, "Dr Elliot" hardly ever That he had an abiding interest in and affection for his first profession, medicine, there can be no question He served effectively as Under-Secretary for Health at the Scottish Office and as Minister of Health in Whitehall Yet he gave the impression that he was mindful of the saying current before his time in the Ministry that "doctors do not make good Ministers of Health" and preferred to base himself on a Parliamentary rather than a medical reputation He was not outstandingly active in the negotiations and debates over the National Health Service Bill But his position in recent years as a vigorous and respected back-bencher is unassailable and he was prominent in the discussions in the Conservative "1922 Committee" The niche he cut for himself was as an interpreter of back-bench opinion to Cabinet Ministers and as an interpreter of the Cabinet to the parliamentary party He could speak with freedom in both circles, knowing that his opinions would be listened to I can recall more than one occasion when tensions were resolved by his intervention at party meetings

His capacity for friendship, his wise and well-stored mind, and his exceptional experience meant that he was often called to head delegations and to speak as a representative parliamentarian This was a role in which he seemed more at home than in the rough and tumble of party politics—though he never disdained the dust and turmoil of party conflict—and will be the contribution to the work of the House of Commons for which he will be gratefully remembered by those who worked with him The House needs a handful of statesmen free to move at need above the arena of our daily concerns Walter Elliot, by his natural endowments, his personality, and his experience was one of these The House has too few of them and his death is a real loss **H L**

Though Elliot did not return to Ministerial office after 1940, as these tributes show he continued to give much valuable service One of his interests in these last years linked him once more directly to medicine, and of his presidency of the Royal Institute of Public Health and Hygiene J B A, who had known him since they were both students in Glasgow, writes

Immediately after the first world war I, then an R M O at the Royal Chest Hospital of London, renewed my acquaintance with Walter Elliot who, though his foot was on the first rung of the political ladder, was at that time interesting himself in public health and acting as a part-time assistant to a medical officer of health in a London borough We had many conversations over lunch at the hospital and I was impressed with the keen interest which he took in preventive medicine Later it was my privilege as a member of council of the institute to approach Elliot to ascertain whether he would be willing to become our president It was characteristic of the man that he did not accept this office before acquainting himself with the work and activities of the institute From his election in 1946 he was not only a figurehead but an active president, and on many occasions he addressed from the chair the fellows and members

Behind the public figure there remained the man, and of him his friend T J H writes

Walter Elliot carried his sense of fun through every phase of his career His interests were multiple and if he took up a subject he made it his business to master it He was a friendly man, and although as a public figure he had his critics, over the years he never lost his capacity for making and holding friendships The distinctions and honours which were conferred on him reflect in some measure the great services so cheerfully given in and out of office, academic and political He was bound to meet with disappointments and frustrations, but he appeared to regard them as part of the art of living, and never permitted sourness, bitterness or regret to mar his countenance or speech A very full life has reached its close In many and different circles, particularly in Scotland where he was respected, admired, and loved, it will be a long time before we become accustomed to the idea that Walter Elliot is no longer with us

Elliot died on Jan 8 at his home in the Borders and is survived by his second wife, formerly Miss Katharine Tennant

Miss EDITH HALL

H M M M writes

Edith Hall was elected obstetric surgeon to the Mothers' Hospital, London, in 1923 She held this post for about 26 years and was latterly chairman of the medical committee Her warm human kindness, understanding, and integrity earned the affection of all who knew her, and her obstetric and gynæcological skill and judgment won the confidence of those who worked for or with her At the end of a hectic day, one of her registrars remarked that when obstetric emergencies and anxieties piled up in the wards and labour-rooms, the arrival of Miss Hall in the hospital brought immediate relief and a sense of calm—a spontaneous tribute which reflects the remarkable influence she possessed, as well as being a tribute to her outstanding ability as an obstetrician Her wisdom and personality were a valued asset both to the Mothers' Hospital and to her colleagues, and her resignation, when she found her professional burden too heavy, was a lasting loss The sympathy of all who knew her goes out to her sister and close friend, Dr Marjorie Hall

Notes and News

CONTROL OF NARCOTICS

In its report[1] for 1957, the Permanent Central Opium Board of the United Nations says that the operation of the system of control of narcotics has improved in the past five years, statistics have been fuller, more accurate, and more promptly submitted, though some countries cooperate less well than others The board deals with *all* narcotic drugs

One of the effects of the controls introduced in 1925 and 1931 has been that it is now almost impossible for addicts to get narcotics from legal sources The legal production is virtually limited to medical and scientific needs, except in the case of coca leaves and cannabis, the quantity of coca leaves produced for chewing is unknown but was not less than 9600 tons in 1956 (thirty times the production for medical use) From 1955 to 1956 the quantity of opium produced decreased, while the amount used in medicine increased Only three countries manufactured heroin in 1956, and the international trade was negligible (1 kg) 32 synthetic narcotic drugs were controlled by 1956, pethidine is by far the most commonly used, the United States accounting for two-thirds of world consumption.

NOTIFICATION OF ACUTE RHEUMATISM

Under the Acute Rheumatism Regulations, 1953, the disease must be notified in Cornwall, parts of Lindsey, the county boroughs of Bristol, Grimsby, Hull, Lincoln, Salford, and Sheffield, and the borough of Ilford These regulations have now been extended indefinitely It is possible, the Ministry of Health says, that the areas in which the disease is notifiable may later be increased

LESSONS IN REPRODUCTION

There has appeared a sprightly little picture-book[2] of first lessons in human reproduction and sex for four-to-eight-year-olds and their parents The line drawings, by Gerda Nystad, of children and young adults, clothed and naked, are modest and pleasing, and the text shows well how to say enough and not too much to the inquiring child The sketch of the unborn at ease in a womb without exit but pierced by an umbilical feed-pipe seems a little fanciful in such factual context, but the book should both please and profit those it is meant for

NEW MEDICAL FILMS

Acidity, Dyspepsia, and Peptic Ulcer (16 mm , sound, colour, 28 min , Britain, 1957) presents dyspepsia as an imbalance between gastric acidity and tissue resistance

It shows that statistically there is a relationship between acidity and the incidence of peptic ulcer, but ulcers that arise where acidity is normal indicate a low tissue resistance Methods of measuring gastric acidity are shown and the histamine response is described. In the second half of the film the cause of pain is considered and methods of reducing the acidity mentioned Finally, the advantages are set out of a proprietary preparation for this purpose

The film gives a concise exposition on the modern view of dyspepsia but the emphasis on a particular treatment detracts from the value of the film for teaching purposes The commentary is excellent and carries the weight of the exposition The picture is largely diagrammatic and at times the artist seems to be hard pressed to fill the screen with appropriate symbols to match the lecture. The film may be obtained free from C L Bencard, Ltd , *Minerva-road*, Park Royal, London, N W 10

The Manchester Regional Hospital Board is responsible for a film, *There was a Door* (35 mm , sound, black and white, 30 min , Britain, 1957), on mental deficiency

Taking as its text " It is not in the best interests of patients fit to live in the general community that they should live in large and remote institutions—cut off from the world " (from the report of the Royal Commission on Mental Illness) the film discusses the problem of the overcrowding of hospitals with mentally deficient patients, many of whom could be trained to undertake suitable work and live at home. The training centre at Oldham is described, and municipal and county authorities are encouraged to set up similar centres for the training of mental defectives in their areas

The film puts extremely well the case for keeping mentally defective patients out of hospital, this coincides with the recommendation of the Royal Commission, though the film was in production before the report was published The film is designed primarily for local health authorities, and it is therefore surprising that some patients with extreme mental deficiency, who are unsuitable for training, are shown in the film. Indeed the film should be very carefully introduced when shown to non-medical audiences The production is of professional standard. The film is available on hire from Sound Services, Ltd , 269, Kingston Road, London, S W 19 16 mm prints will probably be available shortly

Nobecutane—A Plastic Surgical Dressing (16 mm., sound, colour, 23 min , Britain, 1957) describes the properties and uses of the plastic skin dressing in surgery and other fields

The film mentions its advantages over conventional dressings, and shows in detail its application to an operation wound and the subsequent removal of sutures Other varied situations are named where the dressing has proved valuable, and the film ends with a summary of its properties

This is a very good film that convincingly presents the advantages of the plastic dressing A black and white sequence of the Korean war could be omitted, but otherwise the pictures and commentary contribute equally to the smooth exposition The colour photography is excellent and the commentary authoritative and clear The film is available free from the Film Library, Evans Medical Supplies, Ltd., Liverpool

The following diplomas were granted jointly with the Royal College of Physicians

D L O—Paul Abbey, Rasheed Ahmad, Z H Alvi, Julian Bihari, Thomas Cartmill, R R A Coles, B R Das, M J D Cruz, J L Golden, John Hall-Jones, Martin Horowitz, Y P Kapur, G M Khan, F W Kwok, Ishwar Narain, N B Parvathiah, Jeffery Potter, L N Prasad, Rajendra Prasad, I P C Robertson, D S Sardana

D A—F D Adrianvala, Eleanor K Althorp, Edna W Anthony, N K Ashurst, Roma M Bedford, Abraham Berry, Jane I K Binnie, H L Blake, Margaret A E Boyce, J H Breed, R A Butler, P H Byles, Joan M Byrne, Po Sing Chau, J M Clark, R J Clark, W H Cochrane, G F Conway, S K Coombes, H B Coulter, Bridget M Cowley, H J L Craig, J P Czyniewski, M A de Valero Wills, B J Dolan, R R Evans, A D J Farquharson, M E Fielding, G Flowers, H J Freedman, B L Gupta, V G Gurjar, Christopher Gyaw, R W Hall, D D Hart, D F Hogan, Margaret C Holderness, W G Holland, Ann Horsburgh, T H Howells, Ayesha S Ishrat Husain, M O N Iyengar, T E Jones, V R Jones, Kathleen E Kennedy, J C Kennedy Smith, J D Kinnell, R J Knight, H P Lacey, R Grove Lacey, Anatol Lagowski, G L F Lau, P D Lawler, J L Layng, Phyllis L Liddle, G J M Lincoln, J V McCooey, P W McCormick, S W McGowan, N N Madan, R E W Manley, R R Manning, Maung U Win, T W P Millar, J S Miller, Mary H Miller, D R Morgan, Ada C Morrison, Joyce Newman, B A Nixon, Krishnapathee Parbhoo, T F J Parker, A S Paton P A P Pompa, Diana Ratcliffe, D D G Simpson, Chanan Singh, Harold Slomowitz, J A Stainton Ellis, K D Stephenson, C R Sulochana, N S Thomas, J S Toner, Patricia A Topham, Sohrab Rustomji Umrigar, R D Unkles, Sariphorn Vanikieti, F H Walter, Elizabeth M B Watson, A I Weinreich, J M S Whiting, D C M Wilcox, P F Willis, J E York, Freda Young

D M R D—D A Alderson, Keith Ashcroft, Kyaw Aung, W R Barrow, D C Bernstein, M P Bhalla, Savas Bissylass, H J Bloch, Ronald Cable, D F Cantwell, George Cohen, I D Davies, M L Dyson, R F Fouche, John Fraser, R W Galloway, J J Gately, Kenneth Grainger, Ian Isherwood, Naphtali Joffe, Brigid Keane, J T Lamb, James Lees, J J D Lobo, A B McGrigor, M R H Mahmood, R C Michell, N L Mills, Israel Movsas, N D C O'Connell, Irmgard Patton, J J Prior, K D Reddy, Percy Reichman, Broughton Ridgway, J H Rustage, Ahmed Sardar, H M Saxton, S N Sender, M P Shannon, Eli Sheville, M J Strachan, H M Strathern D F Street, Geoffrey Sullivan, S N B Talwatte, Sneh Taneja, R P Vass, Peter Ward, W L Wong

D P M—G H Armitage, Grace Bainbridge, A H Borowitz, A M Bradfield, S W G Caseley, M R Chaudhry, A B Cooper, F H Corbitt, J McK Davie, R N Davis, Joseph Erulkar, G W Fenton, Albert Gage, M E Grant, Ian Hadfield, Lewis Harris, Peter Hays, G A Heasman, Mary K P Henderson, William Leggat, Kypros Loucas, N C Low, S M Macentee, N K Macrae-Gibson, W K Marshall, Pamela G L W Mason, W J Nicholson, V R Ntsekhe, P M J O'Brien J R Palmer, Barbara Petrovskaia, Abe Pick, E W Poole, J H Price, J R Roy, Barbara J Salisbury, G H Scott, J C Scott, Karam Singh, W B Spry, J S Stead, A A Sugerman, S S Syalee, W D Wilson, Waclaw Wollen

D T M & H—H F McElligott, Umasanker Sahay, Thambo Tharmaratnam

D Path—B B Beeson, P W J Bosman, S M Deoras, Geoffrey Garrett, Barbara E Grahame, I J Hunter, Felix Kurrein, C J McDonald, James Ward

D P H—Mary M M Boyd, M J Catton, M L Graeme, Bashir Hussain, P V Krishnamurti, C L Milburn, S K Sen, Tin U, E J Wright

National Association for Mental Health

This association is holding a conference on the report of the Royal Commission on the law relating to mental illness and mental deficiency, on *March 6* and 7, at Church House, Westminster, S W 1

The speakers will include Dr W A L Bowen, Dr D H Clark, Dr J D Kershaw, and Dr Denis Leigh Further particulars may be had from the conference secretary of the association, 39, Queen Anne Street, W 1

Chronic Rheumatic Diseases

A weekend course with lectures, ward rounds, and practical demonstrations will be held at the rheumatism unit of St Stephen's Hospital *on March 15* and 16

Professor J Trueta will open the course, and the speakers will include Dr Francis Bach, Dr Grace Batten, Dr Raymond Daley, Dr Philip Ellman, Mr H E Harding, Dr F Dudley Hart, Dr R H Marten, Mr G Pritchard, and Dr Gordon Signy Further particulars can be obtained from the secretary, Fellowship of Postgraduate Medicine, 60, Portland-place, W 1

Appointment in Northern Ireland

Dr W McCartan, who recently retired from the post of physician-superintendent of St Francis and Hurstwood Park Hospitals, Haywards Heath, has been appointed medical inspector of mental hospitals in Northern Ireland in succession to Dr F G L Barnes

International Congress of Physiological Sciences

This congress will be held in Buenos Aires from Aug 9 to 15, 1959 Further particulars may be had from the secretary, Facultad de Ciencias Medicas, Paraguay, 2151

London Skin Hospital

In accordance with the decision of the North West Metropolitan Regional Hospital Board, this hospital will be closed for *the* treatment of skin conditions on *March 31* Patients still under treatment at that date will be referred to their general practitioners New patients will not be accepted after Feb 14

Dr J A Fraser Roberts has been elected president of the Royal Anthropological Institute

---

CORRIGENDUM *New Year Honours*—We regret that through our mistake the name of Dr Clarence Smith appeared twice in our list of medical honours (Jan 11, p 100) Dr Smith in fact was appointed O B E

Diary of the Week

JANUARY 19 TO 25

Monday, 20th

HUNTERIAN SOCIETY
8 30 P M (Mansion House, E C 4) Sir Ernest Rock Carling Biological Systems and Atomic Radiation (Hunterian lecture)

Tuesday, 21st

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W 1
8 P M *Pathology* Prof J Firket (Liège) Cancer of the Lung in the *Industrial Area of Liège* during Recent Years
BRITISH POSTGRADUATE MEDICAL FEDERATION
5 30 P M (London School of Hygiene and Tropical Medicine, Keppel Street, W C 1) Dr L H Gray Influence of Oxygen on the Response of Cells and Tissues to Ionising Radiation
ST MARY'S HOSPITAL MEDICAL SCHOOL, W 2
5 P M Prof Charles Rob Ileus
INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, Gray's Inn Road, W C 1
5 30 P M Prof F C Ormerod Sinusitis
INSTITUTE OF DERMATOLOGY, Lisle Street, W C 2
5 30 P M Dr R H Meara Skin Diseases in Children I
SOCIETY FOR THE STUDY OF ADDICTION
8 P M (11, Chandos Street, W 1) Sir Adolphe Abrahams Use and Abuse of Drugs by Athletes
MANCHESTER MEDICAL SOCIETY
4 30 P M (Medical School, University of Manchester) Prof Robert Platt, F R C P Darwin, Mendel, and Galton
UNIVERSITY OF ST ANDREWS, Queen's College, Dundee
5 P M Prof A E Ritchie Methods of Artificial Stimulation and Potential Recording in Neuromuscular Disorders

Wednesday, 22nd

ROYAL SOCIETY OF MEDICINE
5 P M *Endocrinology* Dr Sheila Sherlock, Dr Julius Lee, Dr G W Bisset, Dr W H Summerskill Endocrine Changes in Liver Disease
POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W 12
2 P M Dr R R Race Contributions of Blood Groups to Human Genetics
INSTITUTE OF DISEASES OF THE CHEST, Brompton S W 3
5 P M Sir Russell Brock Basic Principles in Heart Surgery
INSTITUTE OF DERMATOLOGY
5 30 P M Dr Henry Haber Cellular Nævi
NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY, 64 St James's Street, Nottingham
8 30 P M *Dr C A Boucher Accidents in the Home*
MANCHESTER MEDICAL SOCIETY
4 30 P M (Medical School) *Medicine and Pathology* Prof Alexander Haddow Recent Trends in Cancer Research

Thursday, 23rd

UNIVERSITY COLLEGE LONDON, Gower Street W C 1
5 P M Dr E Lester Smith Biochemical Functions of Vitamin B_{12}
ROYAL SOCIETY OF MEDICINE
8 P M *Urology* Prof N F Maclagan Urinary Colloids Mr J H Carver Bilateral Orchidopexy and Fertility Mr Norman Slade *Bacteræmia and Septicæmia* after Urological Operations

5 30 P M Mr G H Howells Malignant Diseases of the Accessory *Sinuses*

The Lancet · Saturday 25 January 1958

BETWEEN GUESSWORK AND CERTAINTY IN PSYCHIATRY *

AUBREY LEWIS
M.D. Adelaide, F.R.C.P
PROFESSOR OF PSYCHIATRY, UNIVERSITY OF LONDON

IT is the common state of reflective and inquiring minds to be somewhere between untrammelled guesswork and certainty It would be discreditable if psychiatrists were huddled at either extreme, wholly engaged in guessing or ignorantly certain We are, however, sometimes suspected of luxuriant speculation and of invincible faith in our tenets and I propose to consider how this reputation has arisen

More than most branches of medicine, psychiatry can be regarded as an art One of its distinctive procedures—psychotherapy—manifestly depends on subtle relationships and incommunicable qualities of personality But in the proportion that it is an art, psychiatry is a weak branch of medicine and the constant aim of those who would further and strengthen it is to apply to it the methods of scientific inquiry If these result in encroachments on the area reserved for the art of medicine, and substitute assured knowledge for assumptions and intuitions, so much the better This is not to deny the large part which compassion and human feeling must play in the care of mental disorder its history attests that they will always be necessary, but they operate in a territory that must be explored and charted Psychiatry in this is like the rest of medicine, combining moral and personal principles of action with those arrived at by the methods of science, and depending on the last for any increase in its power to prevent and control disease

There is a large subcontinent of psychiatric research which is concerned with applying the methods of the natural sciences to morbid phenomena—biochemical and physiological investigations in mental disorder are obviously of this nature Psychological and sociological inquiries are in another area, that of the social sciences Many studies in psychiatry lie in both areas—because they are intermediate, as physiological psychology is, or because they are carried out through joint activities Much controversy has centred on differences between the methods of the natural sciences and of the social sciences, stressing the relative weakness of the latter Weaknesses in the social sciences—immaturity in their *technical* procedures, laxity in their theorising—*will tell* heavily against psychiatric advance It is true that some psychiatrists distrust the social sciences so much that any excursion in that direction is for them tantamount to walking the plank Nevertheless the part that psychology and sociology must play in the advancement of psychiatry is undeniable

Though there is manifest convenience in distinguishing between the natural and the social sciences, fundamental difference between them cannot be discerned The slower tempo of development in the social sciences, and the immense difficulties in the way of measuring and controlling the phenomena they study, cannot be gainsaid, but the social, like the natural, sciences depend on sense-data, are nourished on hypotheses, and ask to be continually corrected through experiment and enlarged through further observation If psychiatry were to put all its hopes in the application of the natural sciences and were to claim exemption from the discipline of the social sciences, it would be aligning itself, along a large stretch of its front, with *dead philosophies* and cults in which doubt is repudiated for the sake of a limited and spurious inner consistency

* * *

The scientific method, which has been so closely studied of late by philosophers, is not, of course, the preserve of the natural sciences (though to them it owes its enormous prestige) Whether in the physical, the biological, or the social sciences, there is the same essential passage from untested guess to tenable, unfalsified conclusion—which may be, rather loosely, called a confirmed conclusion or a certainty, in the sense in which the circulation of the blood is a certainty The initial hypothesis is arrived at by divers routes, about which on the whole little is known deductions from it entail predictions which are put to the test of direct observation or contrived experiment and when enough evidence in support of the hypothesis has accumulated, it is given provisional acceptance In time statements are thus arrived at which embrace and order very many facts, these statements have always started as hypotheses, plausible guesses

It is a commonplace that hypotheses are indispensable for scientific activity, and that hypotheses must be judged by their heuristic as much as by their veridical importance inadequate or false hypothesis may have value in provoking further observation and experiment. "Even *mistaken* hypotheses are of use in leading to discoveries", wrote Claude Bernard "It seems indeed a necessary weakness of our mind to be able to reach truth only across a multitude of errors and obstacles" De Morgan put it in a telling paradox—"Wrong hypotheses, rightly worked, have produced more useful results than unguided observations" the phlogiston theory or the corpuscular theory of light illustrates his point It is equally a commonplace, however, that hypotheses are an impediment to knowledge when they are so loosely formulated that we cannot deduce their logical consequences and therefore cannot make predictive statements which could be verified or refuted, the systematists of the 18th century exemplified this in medicine Moreover, it is a poor recommendation in favour of a certain hypothesis to say that it explains all we know, for, as Karl Popper emphasises, it is only by testing it on seemingly contrary instances that we can carry out that determined effort at refutation which is what we really mean when we speak of verifying a hypothesis Interpretations which explain the phenomena only too readily, lead to a feeling of certainty which *closes* the mind to further inquiry and makes the believer hostile to any breath of scepticism

I mention these familiar considerations because they have a direct relevance to some puzzling features in the development of psychiatry In spite of the sophistication apparent in its literature, psychiatry is in some important respects struggling with problems which beset the physical sciences three hundred years ago The word "hypothesis" was a bad word in the 17th century.

"Hypotheses non fingo", said Newton "Hypotheses, *whether metaphysical* or physical, have no place *in science*" (Quicquid enim ex phenomenis non deducitur hypothesis vocanda est, et hypotheses seu metaphysicae seu physicae seu qualitatum occultarum seu mechanicae in philosophia experimentali locum non habent) Indeed, Newton lost no opportunity to belittle them, as in a letter to Oldenburg in 1672 where he wrote "I do not think it needful to explicate my doctrine (of colours) by any hypotheses at all You see therefore how much it is besides the business in hand to dispute about hypothesis For which reason I shall now proceed to abstract the difficulties involved in Mr Hooke's discourse, and without having regard to any hypothesis consider them in general terms "

---

* The Bradshaw lecture for 1957, delivered before the Royal College of Physicians on Nov 7

It is a little odd that the most illustrious scientist whom England has produced should have spurned what men now regard as an essential element in the process of arriving at truth Surely a semantic misunderstanding But a widespread one Let us look at a great medical contemporary of Newton's Thomas Sydenham wrote, in the Preface to his Observations, that hypotheses should be laid aside, in the study and description of diseases, "for 'tis difficult to give a detail of the errors that spring from hypotheses, whilst writers, misled by these, assign such phenomena for diseases as never existed but in their own brains", and similarly, in his letter to Dr Paman, he speaks sharply of the many authors whose "writings are founded upon Hypotheses which are the result of a luxuriant imagination, and the symptoms of diseases (wherein their true history consists) as described by them, appear to be deduced from the same source, and the method of cure, also, is derived from the same fictitious principles, and not from real facts, and thus becomes most destructive to mankind, so full of specious reasoning is every page of the writings of such superficial men, whilst the directions of nature are overlooked "

A hundred years later Pinel was still writing in the same strain, rejecting "toute discussion métaphysique, toute hypothèse sur la nature des fonctions intellectuelles ou affectives, sur leur genération, leur ordre, leur enchaînement réciproque "

It is plain that in those days hypotheses had a bad name because they connoted speculative propositions, so tenaciously held that conclusions derived from observation were rejected if they conflicted with them It might be assumed that hypotheses no longer carry this taint Yet in the introduction to a recent English textbook the authors review the requirements for a scientific approach and then say

> "It is embarrassing that such basic ideas of scientific method should have to be repeated and discussed in a textbook of psychiatry, but not one of these requirements is met by a very large part of the contributions which are made to contemporary psychiatric literature Hypotheses are reared in a vacuum without logical basis, and are expressed in imprecise phraseology in terms which have not been defined They are often so vague that it is impossible to draw logical consequences, but even when that can be done critical investigations are not made (Workers') hypotheses serve the single aim of providing a framework for interpretation " (Mayer-Gross, Slater, and Roth 1954)

These strictures echo the complaints from the 17th century and are voiced, from a more detached standpoint, by a medical historian reviewing the theory of psychoanalysis

> "a 'system' explaining in logical sequence the origin, nature and treatment of all disorders of a given class is suggestive—within the mental field—", says Richard Shryock, "of those general medical systems which were so typical of the eighteenth and earlier centuries If, like the latter, psychoanalysis cannot be checked one way or the other, it represents a reversion to the system-making stage in medical methodology, and may be expected to reproduce the various features and developments typical of that level It is suggestive that this is indeed just what has happened Once more, within this particular field, one hears of masters and disciples, of divergent 'schools', of scientific controversies in which there is an 'attack' or a 'defence' of a given system, with more or less feeling on both sides "

A more recent censure, by outspoken psychiatrists, is that of Lemkau and Pasamanick, who, contemplating the preventive powers at our disposal, wrote in 1953

> "The flashes of insight that have characterized the great leaders of our field in the past must be documented painstakingly with proof, a type of scientific discipline of which psychiatrists are perhaps more derogatory than appreciative "

Whether these severe judgments are unfair is less important than that they repeat a pattern of criticism which is neither unfamiliar, nor confined to psychiatry and psychoanalysis Historians have similar hard things to say about Prof Arnold Toynbee Sociologists note such frailties in other sociologists And in the most entrenched and assured branches of medicine critics sometimes discern them too As an unsparing observer of loose thinking in medicine noted, the dividing wall between an unconfirmed hypothesis and a valid explanation often disappears, especially in therapeutics, because autistic aims prevail over rational thought (Bleuler 1927). This is nothing new "the human understanding resembles not a dry light, but admits a tincture of the will and the passions for man always believes more readily that which he prefers his feelings imbue and corrupt his understanding "

* * *

It would be easy to pile up instances showing that psychiatry is not the only branch of medicine—or of knowledge—to be pilloried for lax thinking and complacent dogmatism It has, however, troubles which seem peculiar to itself, and some ministrants who seem peculiarly indifferent to the scientific method as understood by the rest of the world Nevertheless, I doubt if these are special characteristics psychiatry's troubles are those inherent in the study and improvement of human behaviour, psychiatrists are for the most part bent, like other doctors, on doing their best for patients according to current methods and theories, without stopping to pick up and examine the little hedgehogs of doubt that sit by the therapist's path There is nothing specially psychiatric about that Besides those undoubting psychiatrists engaged mainly in treatment, there are in many countries psychiatric investigators fully alive to the rigorous demands of research but equally alive to the extreme complexity of their problems

This complexity can be well seen when the value of treatment is reviewed It has been said that "psychotherapy is where organic medicine was in the days of Paracelsus" this gross exaggeration attests the gloom which some feel when they try to judge the present position of psychotherapy, and indeed of psychiatric treatment in general Has the psychiatrist culpably failed to observe elementary principles of trial and evaluation, or has he attempted the task but found it too formidable? The question is not a rhetorical one To answer it, the evaluation of psychiatric treatment has to be looked at more closely

* * *

The aims of medical treatment are ordinarily to remove or lessen disabilities and pain, to put an end to morbid changes in the patient's body of which he may not be aware but which must sooner or later cause disability, and, thirdly, to enable him to live as satisfying a life as possible, in spite of persistent disability and morbid process Applied to mental illness, all this becomes equivocal The patient will often be unaware of disturbances very plain to others, he may not complain of his symptoms, he may even cherish them He may lead a less satisfying life when his symptoms have been got rid of than when he had them. The morbid process often has no physical substrate that we know of and the psychopathology may be obscure and inaccessible The criteria of recovery are therefore hard to specify, and, like the criteria of improvement depend on an assessment of the patient's happiness, competence, and wellbeing which involves moral and social values as well as plainly medical ones It must moreover be a comparative assessment, since if the patient was a poor creature—an inadequate psychopath as people now say—before his attack of anxiety and depression came on, it must be counted as recovery if he reverts to his previous state, free again from manifest anxiety and depression, though in another man, previously better equipped to fulfil his social role, an illness that subsided leaving him in a state of inadequacy and social malaise would be rightly regarded as having a bad outcome.

A rather silly but often repeated truism says that the aim of psychiatric treatment is to promote mental health It is hard to tell what the latter phrase means Mental health is an invincibly obscure concept. Those who have attempted to define it in positive terms have twisted ropes of sand, telling us, for example, that a man's mental health consists in

> " (a) active adjustment or attempts at mastery of his environment as distinct both from his inability to adjust and from his indiscriminate adjustment through passive acceptance of environmental conditions, (b) unity of his personality, the maintenance of a stable, internal integration which remains intact notwithstanding the flexibility of behaviour which derives from active adjustment, and (c) ability to perceive correctly the world and himself "

This clutter of words is groping towards an ideal, a sociological ideal but much of it can have no operational referents and it abounds in terms which are undefined and at present undefinable. Most of those who state criteria of mental health follow the lead of the World Health Organisation in refusing to take the absence of disease or infirmity as the characteristic feature, they do not say a man is well when he is free from manifest illness but speak instead of " optimal growth and happiness of the individual ", " full maturity ", " adjustment to the world and to each other with a maximum of effectiveness and happiness ", using quantitative words like " full " and "maximum" to qualify immeasurable states like happiness

* * *

Mental health, we may conclude, is an abstraction which is very loosely interpreted We cannot in every case decide, by comparing the degree of mental health after an illness with that before, whether the patient has recovered, or whether his illness has improved, or is stationary, or worse

It is of course true that in many instances such a difficulty hardly enters anybody's mind, since there is an undeniable change for better or worse in the patient's condition, and everybody entitled to express an opinion—the patient, his relatives and intimates, his doctor—will concur But these cases are not, I think, the majority With an illness such as schizophrenia, or still more perhaps with many neurotic disorders, the issue is not clear cut, there may be sharp differences of judgment about outcome. One psychiatrist can report a rich harvest of recoveries in a series of patients whom another, equally sincere and observant would describe as partial failures of treatment.

This is indeed an obstacle which will persist so long as we have no satisfactory measures of clinical change There is another, worse obstacle—uncertainty as to what would have happened if the treatment had not been administered " We cannot judge the influence of a remedy on the course and outcome of a disease if we do not previously know the natural course and outcome of the disease " The course of a mental illness is affected by so many factors, within the patient and in his environment, it is so subject to unforeseen turns of fortune that a change cannot safely be attributed to therapeutic intervention unless it is frequently and regularly produced or comes prompt on the heels of the treatment. This is of course a common difficulty in therapeutics which can be overcome by rigorous trials using, as controls, patients closely comparable to those who are treated But matching psychiatric groups for this purpose is a daunting business, since they should at least be alike in the distribution of sex, age, intelligence, duration of illness, form and severity of illness, and previous treatment alike also in the physical, and still more the psychological circumstances of their medical and nursing care, except for the particular therapeutic procedure that is on trial It is an exacting affair to match for form and severity patients with illnesses whose somatic pathology is not known and the symptoms of which can be elicited fully only with the patient's concurrence—a requirement often unfulfilled The therapeutic zeal of psychiatrists, now as great as was once their nihilism, militates also against painstaking trial and provisional judgment of various methods of treatment a difficulty in other branches of medicine, too

The delay caused by these impediments is evident in the confused verdict on hypoglycaemic treatment of schizophrenia with insulin Here is a method that has been before the world for over twenty years, widely employed in all civilised countries, and the subject of hundreds of experiments and technical reports Yet it is still in such a dubious state that one can read responsible statements declaring on the one hand that it is " the only effective method of treating early schizophrenia " and, on the other, that " there is no significant difference in the outcome of treatment (of schizophrenia) whether unconsciousness has been induced by insulin or by barbiturates" Leucotomy is in rather similar case, and the medley of " tranquillising " drugs may pass, though more rapidly, into the like chiaroscuro of approval and rejection

* * *

But the doubts which attend physical methods of treatment are dwarfish alongside the giant misgivings and disputes which envelop psychotherapy in dust and fog The trouble is of long standing, and has divided psychiatrists bitterly In the Bradshaw lecture of 1936, the psychiatrist who delivered it said

> " There is practically no evidence in existence as to the efficacy of psychotherapy which is guarded against fallacy in such a way as would entitle it to serious consideration in a court of law Among those ' cured ' by any novel remedy are those who have never had the disease, those who still have it, those who have never had the treatment, and those who would have recovered equally well without it. All these classes are generously represented among those cured by psychotherapy "

After this pungent and uncompromising passage, Professor Mapother went on to express his qualified belief in the usefulness of psychotherapy

' it is time to recognise ', he said, " that the hard-boiled disbeliever in psychotherapy is as dead as Queen Anne The real division is between those who are contented and discontented with the fumblings at present enjoying the name. It would be absurd to deny a certain limited efficacy to psychotherapy."

Since then belief in the efficacy of psychotherapy has become much more general among psychiatrists, and valuable systematic observations like those of Whitehorn and Betz have become available. But the same note, with modifications, can be heard in the following passage from a recent paper by two prominent American psychiatrists:

> "We do have the firmest kind of conviction that psychotherapy carried on under the aegis of medicine provides a type of help which is of the first order of importance. But while admitting the importance and efficacy of psychotherapy in its many forms, we cannot emphasise too strongly the necessity for being as rigorous as possible when we make scientific judgments about the methods, goals and effectiveness of psychotherapy" (Bowman and Rose 1954).

This attitude, moreover, is found among psychiatrists who are constantly engaged in psychotherapy. Thus a veteran psychoanalyst, C. P. Oberndorf, acknowledged the many obscure aspects and unpredictability of treatment, about which psychoanalysts themselves were not agreed, and urged the need for a planned investigation of the results of psychoanalysis.

The psychiatrists I have referred to—and, I should think, the great majority of psychiatrists everywhere—are convinced that psychotherapy is beneficial. But which patients it will benefit, what changes it will effect, whether one form of psychotherapy is more effective than another and if so for which types of illness—these are questions they ask themselves with varying insistence and frustration, distrusting their personal opinions on a matter of this kind, and distrusting the consensus of their fellow experts equally or more—since they know enough of the history of medicine and of human illusions to be aware that what most people are convinced of at a given time is not necessarily true.

Psychiatrists have not yet succeeded in investigating the efficacy of specified forms of psychological treatment for specified mental disorders in a way which satisfies the customary requirements of scientific evidence.

Besides the reasons I have been mentioning, there is the difficulty of accumulating a sufficient number of treated and untreated patients and of withholding treatment which patients desire and which their doctors think would benefit them. Psychotherapy, in its most widely known form—i.e., psychoanalysis—may go on for years, and is more often than not carried out in private practice. To collect the requisite number of comparable patients entails the cooperation of a number of psychiatrists engaged in psychotherapy and requires that their patients should be willingly available for independent examination at various phases of their treatment.

Psychotherapists are seldom sceptical or, as one might say, ambivalent about the treatment they give, and "philosophic doubt" is not in keeping with their metier, many of them would desist from psychotherapy if they ceased to be sure that it is effective. It is therefore asking a great deal to invite them to cooperate, at this time of day, in trying to find out whether they may be deceiving themselves as to the usefulness of their life's work. In my own experience, it has not proved possible to get groups of psychotherapists committed to an adequate planned investigation into the results of their treatment.

Among the main problems to be solved if such an investigation is to succeed are how to measure mental change and how to predict mental illness. Now the measurement of mental functions is an enterprise to which psychologists have addressed themselves with brilliant success, and the prediction of behaviour on actuarial lines has been developed by psychologists also, as the names of T. R. Sarbin, Philip Vernon, and Paul Meehl remind us. It would be natural therefore for psychiatrists to have prayed in aid of psychologists here for flattening the major obstacles and designing the whole investigation with that scientific detachment which psychologists may be supposed to possess in high degree.

Detachment is not always evident in psychologists when they concern themselves with psychotherapy. Some immerse themselves in it wholeheartedly as practitioners, on the American pattern. Others sedulously contemplate the pretensions of psychotherapy, shudder, and denounce its hollowness, they are drawn to it by a fascination like that which God has for atheists. But even if psychologists are sometimes emotionally involved, just as psychiatrists are, there is no doubt that they can contribute notably to the elucidation of a problem which everyone must wish to see solved. They have in fact tackled it, if C. R. Rogers' "client-centred" counselling is to be reckoned as a form of psychotherapy. Their skills are relevant, and in my view indispensable, if we are to emerge from the existing morass—as indispensable as the skills of the psychiatrist. By emergence from the existing morass I mean not just a warranted conclusion that psychotherapy is or is not effective for such and such conditions—though that would be much—but a discriminating set of unrefuted propositions which would define attainable goals appropriate to categories of illness or of personality, classify forms of psychotherapy in terms that could be applied without ambiguity to the practice of any psychiatrist, and provide a more "objective", more public and uncontaminated analysis of the therapeutic process than any now offered.

These may seem overweening hopes, in the light of what we have had for so long. but, even if they were fulfilled it would still be only an instalment, largely empirical, of what is needed to free psychotherapy from clogging uncertainties. Current methods of psychological treatment are, or seem to be, legion, they doubtless include procedures that can do harm, at any rate in irresponsible hands, and for some of them the connection between theory and practice is tenuous, the connection between what is preached and what is done so remote as to be discreditable. Besides these infirmities, there is of course much strength and much achievement. How could it be otherwise when there are so many psychiatrists of great ability and intellectual integrity, broadly trained, and gifted in handling complex relationships with others, who devote themselves without reservation or misgiving to psychotherapy as their main business in life? It is in no sense derogatory of their work to want psychological treatment put on a firmer basis of confirmation and precision than it now has. A fair-minded and illuminating review of psychotherapy in 1955 included the following declaration:

> "In our present ignorance it is practically certain that clients are treated by methods of varying inappropriateness, largely as a function of which therapist they happen to get to. Also it is practically certain that many hours of skilled therapists are being spent with unmodifiable cases, or in the use of techniques which are effective but unnecessarily time-consuming" (Meehl 1955).

This is true, and it has a moral—a moral that can be drawn with special force in a Welfare State like ours, under obligation to provide its citizens with all the approved medical treatment they need. To withhold psychotherapy from any neurotic invalid, or any delinquent, or anyone with psychopathic personality—once it had been demonstrated properly that such treatment would lead to recovery or much improvement in these people—would be indefensible. It would be indefensible, within a comprehensive national health service, even if elaborate treatment were shown to be requisite for many patients. practical objections would be raised, of course, on grounds of cost and the availability of doctors, but the issue turns essentially on whether there is convincing evidence of the value of treatment. The United States Department of Health recently published a book on *Evaluation in Mental Health* which listed and abstracted 980 relevant articles. It concluded " an obvious finding is the thinness of the efforts at evaluation."

Here, then, is a great domain of psychiatric practice in which there has been an excessive proportion of guesswork and rather a lot of subjective certainty. More doubt might have been salutary, for the reason that Bacon stated "if a man will begin with certainties, he shall end in doubts, but if he will be content to begin with doubts, he shall end in certainties." The remedy lies in the hands of psychiatrists and psychologists working together. It will demand a considerable effort of reorientation, and indeed sacrifices, from those psychiatrists who devote most of their time to systematic psychotherapy, and from psychologists it will demand an intimate understanding of the conditions of clinical practice and, indeed, some reorientation likewise.

(*to be concluded*)

LEUKÆMIA AND RELATED CONDITIONS AND THE BLOOD-URIC-ACID

R. A. HICKLING
B.A., M.D. Cantab., F.R.C.P.
PHYSICIAN, CHARING CROSS HOSPITAL, LONDON, W.C.2

GOUT develops very rarely in typical myeloid leukæmia and rarely in typical polycythæmia, but not uncommonly in atypical cases of both these diseases, particularly cases of leukæmia without the very high leucocyte-count (100,000 per c.cm.) in the circulating blood of typical cases, and cases of polycythæmia in which a high leucocyte-count occurs in the circulating blood in addition to the high erythrocyte-count (Hickling 1953). It is in such cases that myeloid metaplasia involving leucoblasts, erythroblasts, and especially megakaryocytes develops.

The association of gout with this type of myeloid metaplasia seems important, and, since a patient may have a high blood-uric-acid level for years without any sign of gout, the present paper is concerned with observations on the blood-uric-acid levels of patients with myeloid metaplasia of the spleen, including some cases of typical myeloid leukæmia, the blood-uric-acid levels being related to the histological changes found in bone-marrow and spleen.

It has been found that there is a very close association between a high blood-uric-acid level and the presence of large numbers of giant cells, closely resembling megakaryocytes, in the bone-marrow and in the tissues affected by myeloid metaplasia. This particular association is the reason why gout is very rare in typical myeloid leukæmia, the cells in the tissues and bone-marrow being chiefly leucoblasts, and why gout occurs more commonly in polycythæmia, in which it has been known for many years that myeloid metaplasia may involve leucoblasts and megakaryocytes in addition to the erythroblasts (Weber 1921).

The relationship between a high blood-uric-acid level and megakaryocyte-like giant cells in the bone-marrow and in the tissues affected by myeloid metaplasia appears to be a reciprocal one, because, when a leukæmia-like disease develops in a patient who has had gout for years, it is an atypical leukæmia, often an " erythroleukæmia ", the leucocytes not reaching " leukæmic " numbers, and the tissue changes are those of " megakaryocytic myelosis ", sometimes with sclerosis of the bone-marrow in addition to large numbers of megakaryocyte-like giant cells. This is of great importance in considering the ætiology of leukæmia, because very few conditions are known to cause myeloid metaplasia, the essential feature of myeloid leukæmia.

Observations

These statements are based upon observations of the blood-uric-acid levels in 58 patients, who have as common factors massive myeloid splenomegaly, with various associated changes in the circulating blood, the most important of which is the presence of immature leucocytes. The number of leucocytes in the circulating blood and the percentage of immature cells vary very greatly through the series, from the typical cases of myeloid leukæmia, with more than 100,000 per c.mm. and a considerable proportion of immature cells, to the leucopenia, with a very low proportion of immature cells, of a few cases of " megakaryocytic myelosis ", polycythæmia, or osteo- or myelo-sclerosis. But the detection of immature red and white cells in the circulating blood is of very great importance in the diagnosis of myeloid splenomegaly, and other signs of this may be basophilia, sometimes very high, and eosinophilia.

The 58 cases may be classified as follows:

13 cases of myeloid leukæmia with typical circulating blood, in 5 of which histological findings are available.

4 cases of myeloid leukæmia in which, before treatment, the leucocytes did not reach " leukæmic " numbers (about 100,000 per c.mm.), histological findings are available in 2 of them.

10 cases of polycythæmia, in 8 of which histological findings are available.

11 cases of osteosclerosis, with distinct radiological changes in the bones, in 10 of which histological findings are available.

11 cases of myelosclerosis, in all of which histological findings are available.

6 cases of " megakaryocytic myelosis," in all of which histological findings are available.

3 cases of chronic non-leukæmic myeloid splenomegaly (Witts 1956), in all of which histological findings are available.

These divisions are made for convenience only, and many cases could be put into other divisions. For example, 1 patient with myeloid leukæmia had considerable megakaryocyte proliferation in the bone-marrow, all the patients with polycythæmia had well-marked megakaryocytic proliferation in the bone-marrow or in the tissues, or in both, 2 of the patients with megakaryocytic myelosis had some very fine sclerosis of the bone-marrow, and several patients with osteosclerosis and with myelosclerosis had considerable megakaryocytic proliferation of the bone-marrow in addition to the sclerotic changes. The relationship between these cases is discussed later.

To save repetition, throughout the paper figures for blood-uric-acid levels indicate the number of milligrammes in 100 ml. of blood, the estimations being made on blood-serum. The term giant cells means giant cells closely resembling megakaryocytes, as these appear in sections of bone-marrow.

MYELOID LEUKÆMIA

Of the 13 patients with typical circulating blood 12 had uric-acid levels of 3 1–6 6 mg except for short periods at the beginning of X-ray treatment, when levels of 7 0–9 5 mg were found, the levels later returning to the previous values 5 patients died of myeloid leukæmia, but no histological findings were available In 5 cases histological findings were available, and the proliferation of the bone-marrow and the myeloid metaplasia of the tissues was predominantly leucoblastic without conspicuous giant cells 1 patient had a considerable increase in the reticulin fibres in the bone-marrow together with leucoblastic proliferation 2 patients are still living, with uric-acid levels of 3 4–5 6 mg

4 patients in this group did not have typical leukæmic circulating blood 1 of these had a uric-acid level of 4 0 mg with typical leucoblastic changes in the bone-marrow and typical leucoblastic myeloid metaplasia of the tissues 1 had uric-acid levels of 6 7–11 7 mg (seven estimations in a year) and conspicuous giant cells in the proliferated bone-marrow The 2 other patients had uric-acid levels of 10 0 mg and 9 1 mg , but no histological findings are available None of the patients with myeloid leukæmia had gout

POLYCYTHÆMIA

Of the 10 cases in this group 4 were seen in an early stage, when spleens were not massive, and when there was no leucocytosis and there were either no or very few immature leucocytes in the circulating blood The uric-acid level in all at this stage was 2 1–4 9 mg 1 patient died four years later, but no more uric-acid estimations were made 1 died nine years later and had many giant cells in a sclerotic bone-marrow and in the myeloid metaplasia of the spleen, but no further uric-acid levels were estimated In another patient, however, who is still living, the spleen has become much larger, small numbers of immature leucocytes are constantly present in the circulating blood, the blood-uric-acid level has risen to 7 9–12 0 mg , and bone-marrow biopsy shows a great many giant cells, with some very fine sclerosis The 4th patient, also still living after twelve years' observation, has developed massive splenomegaly, a high leucocytosis (up to 40,000 per c mm), and blood-uric-acid levels of 6 6–7 7 mg No histological findings are yet available

The remaining 6 patients with polycythæmia were seen when already they had massive splenomegaly, with leucocytosis and immature leucocytes in the circulating blood The blood-uric-acid levels in all of them were 6 6–13 3 mg , very often above 7 5 mg 1 patient died seven years after being seen (no histological findings), 1 is still living, in whom bone-marrow biopsy shows a great many giant cells, 1 died after seven years' observation and had a great many giant cells in the bone-marrow, no sclerosis, myeloid metaplasia of the spleen, and very slight myeloid metaplasia of the liver, 1 died after seven years' observation and had a great many giant cells in the bone-marrow, with slight sclerosis in places, 1 died after six years' observation and had a great many giant cells in the bone-marrow, and the last is still living, bone-marrow biopsy showing well-marked giant-cell proliferation, with early sclerosis 5 of the patients with polycythæmia had gout

OSTEOSCLEROSIS

Of the 11 patients in this group, 6 had blood-uric-acid levels of 6 6–12 0 mg constantly, with large numbers of giant cells in the osteomyelosclerotic bone-marrow and large numbers of giant cells in the myeloid metaplasia of the spleen 1 patient had uric-acid levels of 7 0–10 0 mg (eight estimations in two years) with no giant cells in the myeloid metaplasia of the liver or of the spleen (the bone-marrow was not examined) 3 patients had blood-uric-acid levels of 4 0–6 0 mg throughout the period of observation, and there were no conspicuous giant cells in the osteosclerotic bone-marrow or in the myeloid metaplasia of the spleen or of other tissues 1 had uric-acid levels of 5 4–6 6 mg , but the patient is still alive, and no histological findings are yet available 4 of the patients with osteosclerosis had gout

MYELOSCLEROSIS

There are 11 patients in this group In 5 the uric-acid levels were 6 1–7 7 mg (five estimations in a year), 5 7–8 3 mg (four estimations in two years), 7 5–10 7 mg (nine estimations in three years), 7 0–9 0 mg (eleven estimations in five years), and 8 0–10 4 mg (two estimations in four weeks), and all 5 had conspicuous giant cells in the bone-marrow and in the organs affected by myeloid metaplasia 5 had uric-acid levels of 2 8–5 3 mg and no giant cells in the bone-marrow or in the organs affected by myeloid metaplasia 1 patient had uric-acid levels of 2 0–5 8 mg over a period of six months and then 6 7–7 8 mg over the next nine months At necropsy he was found to have a great many giant cells in the bone-marrow, with very fine sclerosis and myeloid metaplasia of the spleen and the liver without conspicuous giant cells The last patient had myelosclerosis with large numbers of giant cells in the sclerotic bone-marrow associated with the presence of malignant cells from a malignant prostate in the bone-marrow He had myeloid metaplasia of the liver and the spleen His blood-uric-acid levels were 5 1–9 6 mg over a period of two years 2 of the patients with myelosclerosis had gout

MEGAKARYOCYTIC MYELOSIS

There are 6 patients in this group, 3 had gout, 2 after the splenomegaly and other features had been recognised, and 1 started to get attacks of gout twelve years before the splenomegaly was recognised 1 patient had uric-acid levels of 6 4–11 4 mg (twenty-one estimations in thirteen years), 1 had 12 5–16 mg over three months, and 1 had 7 8–11 2 mg (four estimations in a year) All 3 had a great many giant cells in the bone-marrow, 2 had localised masses of myeloid metaplasia in the spleen containing very large numbers of giant cells In another patient the uric-acid levels were 5 5–8 6 mg over five months, and he had large numbers of giant cells in the bone-marrow, with very fine sclerosis The remaining 2 patients were exceptions in 1 the uric-acid level was 7 0 mg or higher only five times out of nineteen estimations in six years, but the bone-marrow showed a great many giant cells with doubtful early sclerosis, with myeloid metaplasia of the spleen, and in 1 other patient there was a single estimation of blood-uric-acid (4 5 mg), and bone-marrow biopsy two years later showed large numbers of giant cells with early sclerosis

CHRONIC NON-LEUKÆMIC MYELOID SPLENOMEGALY

3 cases are placed in this group because, though they had massive myeloid splenomegaly, the bone-marrow was normal, being neither hyperplastic nor sclerotic All died of weakness and wasting None had any prominent giant-cell proliferation in the myeloid metaplasia of the spleen or the liver 1, observed for seven years, had blood-uric-acid levels of 2 7–6 3 mg (eight estimations), 1, observed for two months, a uric-acid level of 5 7 mg , and 1, observed for three years, had uric-acid levels of 4 9, 6 7, and 8 0 mg

Throughout the study occasional blood-urea estimations were made (which were always found to be normal) to ensure that raised blood-uric-acid levels were not part of a general retention of nitrogen

Discussion

With few exceptions the blood-uric-acid levels of patients with myeloid leukæmia and related conditions, without conspicuous giant cells in the bone-marrow or in the organs affected by myeloid metaplasia, were between 2 1 and 6 6 mg and of patients with conspicuous giant cells, also with few exceptions, between 6 6 and 12 0 mg These observations suggest that blood-uric-acid levels in myeloid splenomegaly are an important guide to the type of myeloid metaplasia present, and may enable a gradual change in the type of histological change in the bone-marrow and organs affected by myeloid metaplasia to be recognised

A study of cases of myeloid splenomegaly, some of them for many years, suggests certain conclusions

Probably as a result of a metabolic disorder, bone-marrow cells proliferate and blood-cells are formed in the spleen and elsewhere This earliest stage is very rarely seen because it is usually symptomless, but it may occasionally be found in routine examinations, when slight enlargement of the spleen and increase in red cells, white cells, and platelets and slight basophilia in the circulating blood are found, or this stage may be found in the investigation of abnormal hæmorrhage—e g , into the tissues—or in the investigation of gout. There is no information about whether ordinary cases of myeloid leukæmia pass through such a stage, because the known histology of that disorder is the histology revealed at necropsy, but the fact that a few patients with myeloid leukæmia have a raised blood-uric-acid level suggests that there may be a stage of general blood-cell proliferation before the mainly leucoblastic proliferation is established When first seen, most patients have already massive splenomegaly and 100,000 leucocytes or more per c mm in the circulating blood, suggesting that the disorder has been long established before symptoms are sufficiently severe to cause the patient to seek advice.

The first stage, of general proliferation of bone-marrow cells and myeloid metaplasia of the spleen, may be followed by a stage of chiefly red-cell proliferation, when the symptoms and signs of polycythæmia may be produced, and by a stage of chiefly megakaryocyte proliferation, and this by a stage with increasing reticulin proliferation, followed by marrow sclerosis and then by calcification and osteosclerosis The blood-uric-acid level is a guide in tracing these stages, because megakaryocytes in large numbers may persist into the myelosclerotic and osteosclerotic stages or they may be obliterated It is doubtful if myelosclerosis and osteosclerosis occur without a preceding stage with megakaryocyte proliferation. Each of these stages may last many years, and there is no correlation between the underlying pathological state of the bone-marrow and myeloid metaplasia and the clinical and hæmatological features, and this has caused much confusion The best-known types are the chronic cases of megakaryocytic myelosis, myelosclerosis, and osteosclerosis the patients live for years with little interference with their general health, the commonest symptoms being those due to the splenomegaly, and death is ultimately due to weakness, wasting, and anæmia But acute and subacute cases occur in all three stages The acute cases have a course exactly similar to that of acute leukæmia, the patient having pyrexia, severe anæmia, and hæmorrhages and dying in a few weeks or months Even patients with very dense osteosclerosis or myelosclerosis, which probably took many years to develop, may have no symptoms until they manifest an acute illness exactly like acute leukæmia There were 3 acute cases in this series 1 of early myelosclerosis, 1 of dense advanced myelosclerosis, and 1 of dense osteosclerosis Several acute cases have been described (Assmann 1907, Firket and Campos 1922) Subacute cases are those which are seen because of anæmia and weakness, and the patients remain weak and ill throughout the period of observation, unaffected by treatment except temporarily by blood-transfusion There were 6 subacute cases in this series, all of which presented various degrees of osteosclerosis or myelosclerosis, some with and some without conspicuous giant cells among the fibrous tissue Several subacute cases have been described (Wood and Andrews 1949)

Just as there is no correlation between the type of histological change in bone-marrow and spleen and the clinical condition of the patient, there is also no correlation with the state of the circulating blood In a patient with megakaryocytic myelosis, myelosclerosis, or osteosclerosis the numbers of red cells, leucocytes, and platelets may be high, normal, or low, there being very great variations from case to case, and the blood picture may change greatly under observation The great variations in the circulating blood and in the histological picture have been well described (Hutt et al 1953, Richmond and Duncan 1956, Korst et al 1956)

Korst et al (1956) found raised blood-uric-acid levels in 6 of their 23 patients with "myelofibrosis" but did not correlate this finding with histological changes A patient with anæmia may develop polycythæmia (Hutt and Richardson 1950), a patient with polycythæmia may develop "leucoerythroblastic anæmia" (Stone and Woodman 1938), a patient with "leucoerythroblastic anæmia" may develop polycythæmia (Schwarz 1939), a patient with "leukæmic" blood may develop polycythæmia (Major and Weber 1943), and patients may have a blood picture both "leukæmic" and "polycythæmic" (McAlpin 1929, Klumpp and Hertig 1932, Meulengracht and Petri 1932)

6 patients had gout for years before splenomegaly was first discovered because of abdominal symptoms or during the investigation of weakness, cramps in the legs at night, or gout The intervals between the first attack of gout and the discovery of splenomegaly in these 6 cases were three, six, seven, ten, twelve, and forty-one years Only 1 patient was seen before the discovery of splenomegaly gout started in 1929, and he was seen in 1930 because of a large hæmorrhage from the bowel, but the spleen was not felt then, abdominal symptoms, leading to the discovery of a large spleen, developed in 1936 3 of these 6 patients are in the polycythæmia group, 2 in the myelosclerosis group (one very early sclerosis, the other advanced sclerosis), and 1 in the megakaryocytic myelosis group 5 had very large numbers of giant cells in the bone-marrow, and 1 very large numbers in the spleen, with dense bone-marrow sclerosis

If the numbers of leucocytes in the circulating blood in the chronic cases are considerably increased—e g , 30,000 per c.mm —a good response to X-irradiation of the spleen or to busulphan by mouth may be obtained regardless of the type of underlying histology The spleen becomes smaller, the weakness improves, and cramps in the legs disappear Good response to X-ray treatment was obtained in 3 cases of polycythæmia, 3 cases of osteosclerosis, 2 cases of myelosclerosis, and 1 case of megakaryocytic myelosis, and to busulphan in 5 cases, all of which had been treated with at least one course of X rays As with ordinary leukæmia, the effect of treatment lasts a variable length of time, and subsequent courses of treatment tend to have diminishingly good results As opposed to ordinary leukæmia, most patients with a chronic illness die of weakness, wasting, and anæmia, and sometimes chronic gout, without an acute "leukæmic" termination Only 1 chronic case in the series, with dense osteosclerosis, presented a terminal blood picture like that of an ordinary case of myeloid leukæmia with very large numbers of myeloblasts

In only 2 instances in this series was there very evident phagocytosis by the giant cells There was no correlation between large numbers of giant cells in the tissues and large numbers of platelets in the circulating blood Almost always, however, giant platelets were found, and in most cases a few megakaryocytes were, at times, found in the circulating blood These may occur, however, in typical

MYELOID LEUKÆMIA

Of the 13 patients with typical circulating blood 12 had uric-acid levels of 3 1–6 6 mg except for short periods at the beginning of X-ray treatment, when levels of 7 0–9 5 mg were found, the levels later returning to the previous values 5 patients died of myeloid leukæmia, but no histological findings were available In 5 cases histological findings were available, and the proliferation of the bone-marrow and the myeloid metaplasia of the tissues was predominantly leucoblastic without conspicuous giant cells 1 patient had a considerable increase in the reticulin fibres in the bone-marrow together with leucoblastic proliferation 2 patients are still living, with uric-acid levels of 3 4–5 6 mg

4 patients in this group did not have typical leukæmic circulating blood 1 of these had a uric-acid level of 4 0 mg with typical leucoblastic changes in the bone-marrow and typical leucoblastic myeloid metaplasia of the tissues 1 had uric-acid levels of 6 7–11 7 mg (seven estimations in a year) and conspicuous giant cells in the proliferated bone-marrow The 2 other patients had uric-acid levels of 10 0 mg and 9 1 mg , but no histological findings are available None of the patients with myeloid leukæmia had gout

POLYCYTHÆMIA

Of the 10 cases in this group 4 were seen in an early stage, when spleens were not massive, and when there was no leucocytosis and there were either no or very few immature leucocytes in the circulating blood The uric-acid level in all at this stage was 2 1–4 9 mg 1 patient died four years later, but no more uric-acid estimations were made 1 died nine years later and had many giant cells in a sclerotic bone-marrow and in the myeloid metaplasia of the spleen, but no further uric-acid levels were estimated In another patient, however, who is still living, the spleen has become much larger, small numbers of immature leucocytes are constantly present in the circulating blood, the blood-uric-acid level has risen to 7 9–12 0 mg , and bone-marrow biopsy shows a great many giant cells, with some very fine sclerosis The 4th patient, also still living after twelve years' observation, has developed massive splenomegaly, a high leucocytosis (up to 40,000 per c mm), and blood-uric-acid levels of 6 6–7 7 mg No histological findings are yet available

The remaining 6 patients with polycythæmia were seen when already they had massive splenomegaly, with leucocytosis and immature leucocytes in the circulating blood The blood-uric-acid levels in all of them were 6 6–13 3 mg , very often above 7 5 mg 1 patient died seven years after being seen (no histological findings), 1 is still living, in whom bone-marrow biopsy shows a great many giant cells, 1 died after seven years' observation and had a great many giant cells in the bone-marrow, no sclerosis, myeloid metaplasia of the spleen, and very slight myeloid metaplasia of the liver, 1 died after seven years' observation and had a great many giant cells in the bone-marrow, with slight sclerosis in places, 1 died after six years' observation and had a great many giant cells in the bone-marrow, and the last is still living, bone-marrow biopsy showing well-marked giant-cell proliferation, with early sclerosis 5 of the patients with polycythæmia had gout

OSTEOSCLEROSIS

Of the 11 patients in this group, 6 had blood-uric-acid levels of 6 6–12 0 mg constantly, with large numbers of giant cells in the osteomyelosclerotic bone-marrow and large numbers of giant cells in the myeloid metaplasia of the spleen 1 patient had uric-acid levels of 7 0–10 0 mg (eight estimations in two years) with no giant cells in the myeloid metaplasia of the liver or of the spleen (the bone-marrow was not examined) 3 patients had blood-uric-acid levels of 4 0–6 0 mg throughout the period of observation, and there were no conspicuous giant cells in the osteosclerotic bone-marrow or in the myeloid metaplasia of the spleen or of other tissues 1 had uric-acid levels of 5 4–6 6 mg , but the patient is still alive, and no histological findings are yet available 4 of the patients with osteosclerosis had gout

MYELOSCLEROSIS

There are 11 patients in this group In 5 the uric-acid levels were 6 1–7 7 mg (five estimations in a year), 5 7–8 3 mg (four estimations in two years), 7 5–10 7 mg (nine estimations in three years), 7 0–9 0 mg (eleven estimations in five years), and 8 0–10 4 mg (two estimations in four weeks), and all 5 had conspicuous giant cells in the bone-marrow and in the organs affected by myeloid metaplasia 5 had uric-acid levels of 2 8–5 3 mg and no giant cells in the bone-marrow or in the organs affected by myeloid metaplasia 1 patient had uric-acid levels of 2 0–5 8 mg over a period of six months and then 6 7–7 8 mg over the next nine months At necropsy he was found to have a great many giant cells in the bone-marrow, with very fine sclerosis and myeloid metaplasia of the spleen and the liver without conspicuous giant cells The last patient had myelosclerosis with large numbers of giant cells in the sclerotic bone-marrow associated with the presence of malignant cells from a malignant prostate in the bone-marrow He had myeloid metaplasia of the liver and the spleen His blood-uric-acid levels were 5 1–9 6 mg over a period of two years 2 of the patients with myelosclerosis had gout

MEGAKARYOCYTIC MYELOSIS

There are 6 patients in this group, 3 had gout, 2 after the splenomegaly and other features had been recognised, and 1 started to get attacks of gout twelve years before the splenomegaly was recognised 1 patient had uric-acid levels of 6 4–11 4 mg (twenty-one estimations in thirteen years), 1 had 12 5–16 mg over three months, and 1 had 7 8–11 2 mg (four estimations in a year) All 3 had a great many giant cells in the bone-marrow, 2 had localised masses of myeloid metaplasia in the spleen containing very large numbers of giant cells In another patient the uric-acid levels were 5 5–8 6 mg over five months, and he had large numbers of giant cells in the bone-marrow, with very fine sclerosis The remaining 2 patients were exceptions in 1 the uric-acid level was 7 0 mg or higher only five times out of nineteen estimations in six years, but the bone-marrow showed a great many giant cells with doubtful early sclerosis, with myeloid metaplasia of the spleen, and in 1 other patient there was a single estimation of blood-uric-acid (4 5 mg), and bone-marrow biopsy two years later showed large numbers of giant cells with early sclerosis

CHRONIC NON-LEUKÆMIC MYELOID SPLENOMEGALY

3 cases are placed in this group because, though they had massive myeloid splenomegaly, the bone-marrow was normal, being neither hyperplastic nor sclerotic All died of weakness and wasting None had any prominent giant-cell proliferation in the myeloid metaplasia of the spleen or the liver 1, observed for seven years, had blood-uric-acid levels of 2 7–6 3 mg (eight estimations), 1, observed for two months, a uric-acid level of 5 7 mg , and 1, observed for three years, had uric-acid levels of 4 9, 6 7, and 8 0 mg

Throughout the study occasional blood-urea estimations were made (which were always found to be normal) to ensure that raised blood-uric-acid levels were not part of a general retention of nitrogen

Discussion

With few exceptions the blood-uric-acid levels of patients with myeloid leukæmia and related conditions, without conspicuous giant cells in the bone-marrow or in the organs affected by myeloid metaplasia, were between 2 1 and 6 6 mg and of patients with conspicuous giant cells, also with few exceptions, between 6 6 and 12 0 mg These observations suggest that blood-uric-acid levels in myeloid splenomegaly are an important guide to the type of myeloid metaplasia present, and may enable a gradual change in the type of histological change in the bone-marrow and organs affected by myeloid metaplasia to be recognised

A study of cases of myeloid splenomegaly, some of them for many years, suggests certain conclusions

Probably as a result of a metabolic disorder, bone-marrow cells proliferate and blood-cells are formed in the spleen and elsewhere This earliest stage is very rarely seen because it is usually symptomless, but it may occasionally be found in routine examinations, when slight enlargement of the spleen and increase in red cells, white cells, and platelets and slight basophilia in the circulating blood are found, or this stage may be found in the investigation of abnormal hæmorrhage—e g , into the tissues—or in the investigation of gout. There is no information about whether ordinary cases of myeloid leukæmia pass through such a stage, because the known histology of that disorder is the histology revealed at necropsy, but the fact that a few patients with myeloid leukæmia have a raised blood-uric-acid level suggests that there may be a stage of general blood-cell proliferation before the mainly leucoblastic proliferation is established When first seen, most patients have already massive splenomegaly and 100,000 leucocytes or more per c.mm in the circulating blood, suggesting that the disorder has been long established before symptoms are sufficiently severe to cause the patient to seek advice.

The first stage, of general proliferation of bone-marrow cells and myeloid metaplasia of the spleen, may be followed by a stage of chiefly red-cell proliferation, when the symptoms and signs of polycythæmia may be produced, and by a stage of chiefly megakaryocyte proliferation, and this by a stage with increasing reticulin proliferation, followed by marrow sclerosis and then by calcification and osteosclerosis The blood-uric-acid level is a guide in tracing these stages, because megakaryocytes in large numbers may persist into the myelosclerotic and osteosclerotic stages or they may be obliterated It is doubtful if myelosclerosis and osteosclerosis occur without a preceding stage with megakaryocyte proliferation Each of these stages may last many years, and there is no correlation between the underlying pathological state of the bone-marrow and myeloid metaplasia and the clinical and hæmatological features, and this has caused much confusion The best-known types are the chronic cases of megakaryocytic myelosis, myelosclerosis, and osteosclerosis the patients live for years with little interference with their general health, the commonest symptoms being those due to the splenomegaly, and death is ultimately due to weakness, wasting, and anæmia. But acute and subacute cases occur in all three stages The acute cases have a course exactly similar to that of acute leukæmia, the patient having pyrexia, severe anæmia, and hæmorrhages and dying in a few weeks or months Even patients with very dense osteosclerosis or myelosclerosis, which probably took many years to develop, may have no symptoms until they manifest an acute illness exactly like acute leukæmia. There were 3 acute cases in this series 1 of early myelosclerosis, 1 of dense advanced myelosclerosis, and 1 of dense osteosclerosis Several acute cases have been described (Assmann 1907, Firket and Campos 1922) Subacute cases are those which are seen because of anæmia and weakness, and the patients remain weak and ill throughout the period of observation, unaffected by treatment except temporarily by blood-transfusion There were 6 subacute cases in this series, all of which presented various degrees of osteosclerosis or myelosclerosis, some with and some without conspicuous giant cells among the fibrous tissue Several subacute cases have been described (Wood and Andrews 1940)

Just as there is no correlation between the type of histological change in bone-marrow and spleen and the clinical condition of the patient, there is also no correlation with the state of the circulating blood In a patient with megakaryocytic myelosis, myelosclerosis, or osteosclerosis the numbers of red cells, leucocytes, and platelets may be high, normal, or low, there being very great variations from case to case, and the blood picture may change greatly under observation The great variations in the circulating blood and in the histological picture have been well described (Hutt et al 1953, Richmond and Duncan 1956, Korst et al 1956)

Korst et al (1956) found raised blood-uric-acid levels in 6 of their 23 patients with " myelofibrosis " but did not correlate this finding with histological changes A patient with anæmia may develop polycythæmia (Hutt and Richardson 1950), a patient with polycythæmia may develop " leucoerythroblastic anæmia " (Stone and Woodman 1938), a patient with " leucoerythroblastic anæmia " may develop polycythæmia (Schwarz 1939), a patient with " leukæmic " blood may develop polycythæmia (Major and Weber 1943), and patients may have a blood picture both " leukæmic " and " polycythæmic " (McAlpin 1929, Klumpp and Hertig 1932, Meulengracht and Petri 1932)

6 patients had gout for years before splenomegaly was first discovered because of abdominal symptoms or during the investigation of weakness, cramps in the legs at night, or gout. The intervals between the first attack of gout and the discovery of splenomegaly in these 6 cases were three, six, seven, ten, twelve, and forty-one years Only 1 patient was seen before the discovery of splenomegaly gout started in 1929, and he was seen in 1930 because of a large hæmorrhage from the bowel, but the spleen was not felt then, abdominal symptoms, leading to the discovery of a large spleen, developed in 1936 3 of these 6 patients are in the polycythæmia group, 2 in the myelosclerosis group (one very early sclerosis, the other advanced sclerosis), and 1 in the megakaryocytic myelosis group 5 had very large numbers of giant cells in the bone-marrow, and 1 very large numbers in the spleen, with dense bone-marrow sclerosis

If the numbers of leucocytes in the circulating blood in the chronic cases are considerably increased—e g , 30,000 per c.mm —a good response to X-irradiation of the spleen or to busulphan by mouth may be obtained regardless of the type of underlying histology The spleen becomes smaller, the weakness improves, and cramps in the legs disappear Good response to X-ray treatment was obtained in 3 cases of polycythæmia, 3 cases of osteosclerosis, 2 cases of myelosclerosis, and 1 case of megakaryocytic myelosis, and to busulphan in 5 cases, all of which had been treated with at least one course of X rays As with ordinary leukæmia, the effect of treatment lasts a variable length of time, and subsequent courses of treatment tend to have diminishingly good results As opposed to ordinary leukæmia, most patients with a chronic illness die of weakness, wasting, and anæmia, and sometimes chronic gout, without an acute " leukæmic " termination Only 1 chronic case in the series, with dense osteosclerosis, presented a terminal blood picture like that of an ordinary case of myeloid leukæmia with very large numbers of myeloblasts

In only 2 instances in this series was there very evident phagocytosis by the giant cells There was no correlation between large numbers of giant cells in the tissues and large numbers of platelets in the circulating blood Almost always, however, giant platelets were found, and in most cases a few megakaryocytes were, at times, found in the circulating blood These may occur, however, in typical

MYELOID LEUKÆMIA

Of the 13 patients with typical circulating blood 12 had uric-acid levels of 3 1–6 6 mg except for short periods at the beginning of X-ray treatment, when levels of 7 0–9 5 mg were found, the levels later returning to the previous values 5 patients died of myeloid leukæmia, but no histological findings were available In 5 cases histological findings were available, and the proliferation of the bone-marrow and the myeloid metaplasia of the tissues was predominantly leucoblastic without conspicuous giant cells 1 patient had a considerable increase in the reticulin fibres in the bone-marrow together with leucoblastic proliferation 2 patients are still living, with uric-acid levels of 3 4–5 6 mg

4 patients in this group did not have typical leukæmic circulating blood 1 of these had a uric-acid level of 4 0 mg with typical leucoblastic changes in the bone-marrow and typical leucoblastic myeloid metaplasia of the tissues 1 had uric-acid levels of 6 7–11 7 mg (seven estimations in a year) and conspicuous giant cells in the proliferated bone-marrow The 2 other patients had uric-acid levels of 10 0 mg and 9 1 mg, but no histological findings are available None of the patients with myeloid leukæmia had gout

POLYCYTHÆMIA

Of the 10 cases in this group 4 were seen in an early stage, when spleens were not massive, and when there was no leucocytosis and there were either no or very few immature leucocytes in the circulating blood The uric-acid level in all at this stage was 2 1–4 9 mg 1 patient died four years later, but no more uric-acid estimations were made 1 died nine years later and had many giant cells in a sclerotic bone-marrow and in the myeloid metaplasia of the spleen, but no further uric-acid levels were estimated In another patient, however, who is still living, the spleen has become much larger, small numbers of immature leucocytes are constantly present in the circulating blood, the blood-uric-acid level has risen to 7 9–12 0 mg, and bone-marrow biopsy shows a great many giant cells, with some very fine sclerosis The 4th patient, also still living after twelve years' observation, has developed massive splenomegaly, a high leucocytosis (up to 40,000 per c mm), and blood-uric-acid levels of 6 6–7 7 mg No histological findings are yet available

The remaining 6 patients with polycythæmia were seen when already they had massive splenomegaly, with leucocytosis and immature leucocytes in the circulating blood The blood-uric-acid levels in all of them were 6 6–13 3 mg, very often above 7 5 mg 1 patient died seven years after being seen (no histological findings), 1 is still living, in whom bone-marrow biopsy shows a great many giant cells, 1 died after seven years' observation and had a great many giant cells in the bone-marrow, no sclerosis, myeloid metaplasia of the spleen, and very slight myeloid metaplasia of the liver, 1 died after seven years' observation and had a great many giant cells in the bone-marrow, with slight sclerosis in places, 1 died after six years' observation and had a great many giant cells in the bone-marrow, and the last is still living, bone-marrow biopsy showing well-marked giant-cell proliferation, with early sclerosis 5 of the patients with polycythæmia had gout

OSTEOSCLEROSIS

Of the 11 patients in this group, 6 had blood-uric-acid levels of 6 6–12 0 mg constantly, with large numbers of giant cells in the osteomyelosclerotic bone-marrow and large numbers of giant cells in the myeloid metaplasia of the spleen 1 patient had uric-acid levels of 7 0–10 0 mg (eight estimations in two years) with no giant cells in the myeloid metaplasia of the liver or of the spleen (the bone-marrow was not examined) 3 patients had blood-uric-acid levels of 4 0–6 0 mg throughout the period of observation, and there were no conspicuous giant cells in the osteosclerotic bone-marrow or in the myeloid metaplasia of the spleen or of other tissues 1 had uric-acid levels of 5 4–6 6 mg, but the patient is still alive, and no histological findings are yet available 4 of the patients with osteosclerosis had gout

MYELOSCLEROSIS

There are 11 patients in this group In 5 the uric-acid levels were 6 1–7 7 mg (five estimations in a year), 5 7–8 3 mg (four estimations in two years), 7 5–10 7 mg (nine estimations in three years), 7 0–9 0 mg (eleven estimations in five years), and 8 0–10 4 mg (two estimations in four weeks), and all 5 had conspicuous giant cells in the bone-marrow and in the organs affected by myeloid metaplasia 5 had uric-acid levels of 2 8–5 3 mg and no giant cells in the bone-marrow or in the organs affected by myeloid metaplasia 1 patient had uric-acid levels of 2 0–5 8 mg over a period of six months and then 6 7–7 8 mg over the next nine months At necropsy he was found to have a great many giant cells in the bone-marrow, with very fine sclerosis and myeloid metaplasia of the spleen and the liver without conspicuous giant cells The last patient had myelosclerosis with large numbers of giant cells in the sclerotic bone-marrow associated with the presence of malignant cells from a malignant prostate in the bone-marrow He had myeloid metaplasia of the liver and the spleen His blood-uric-acid levels were 5 1–9 6 mg over a period of two years 2 of the patients with myelosclerosis had gout

MEGAKARYOCYTIC MYELOSIS

There are 6 patients in this group, 3 had gout, 2 after the splenomegaly and other features had been recognised, and 1 started to get attacks of gout twelve years before the splenomegaly was recognised 1 patient had uric-acid levels of 6 4–11 4 mg (twenty-one estimations in thirteen years), 1 had 12 5–16 mg over three months, and 1 had 7 8–11 2 mg (four estimations in a year) All 3 had a great many giant cells in the bone-marrow, 2 had localised masses of myeloid metaplasia in the spleen containing very large numbers of giant cells In another patient the uric-acid levels were 5 5–8 6 mg over five months, and he had large numbers of giant cells in the bone-marrow, with very fine sclerosis The remaining 2 patients were exceptions in 1 the uric-acid level was 7 0 mg or higher only five times out of nineteen estimations in six years, but the bone-marrow showed a great many giant cells with doubtful early sclerosis, with myeloid metaplasia of the spleen, and in 1 other patient there was a single estimation of blood-uric-acid (4 5 mg), and bone-marrow biopsy two years later showed large numbers of giant cells with early sclerosis

CHRONIC NON-LEUKÆMIC MYELOID SPLENOMEGALY

3 cases are placed in this group because, though they had massive myeloid splenomegaly, the bone-marrow was normal, being neither hyperplastic nor sclerotic All died of weakness and wasting None had any prominent giant-cell proliferation in the myeloid metaplasia of the spleen or the liver 1, observed for seven years, had blood-uric-acid levels of 2 7–6 3 mg (eight estimations), 1, observed for two months, a uric-acid level of 5 7 mg, and 1, observed for three years, had uric-acid levels of 4 9, 6 7, and 8 0 mg

Throughout the study occasional blood-urea estimations were made (which were always found to be normal) to ensure that raised blood-uric-acid levels were not part of a general retention of nitrogen

Discussion

With few exceptions the blood-uric-acid levels of patients with myeloid leukæmia and related conditions, without conspicuous giant cells in the bone-marrow or in the organs affected by myeloid metaplasia, were between 2 1 and 6 6 mg and of patients with conspicuous giant cells, also with few exceptions, between 6 6 and 12 0 mg These observations suggest that blood-uric-acid levels in myeloid splenomegaly are an important guide to the type of myeloid metaplasia present, and may enable a gradual change in the type of histological change in the bone-marrow and organs affected by myeloid metaplasia to be recognised

A study of cases of myeloid splenomegaly, some of them for many years, suggests certain conclusions

TABLE I—AGE OF PATIENTS

Group	Age (yr)				
	0–20	21–30	31–40	40–50	Total
S	67	653	281	18	1019
S—	60	643	273	24	1000

records were given to the investigator at the end of the puerperium

As soon as the first 200 women had been delivered, the number of toxæmias in both groups were assessed There were 8 in group S, and 12 in group S— Each group contained 100 women It was decided that it was safe to continue the investigation

Results

The investigation started in August, 1954 By August, 1956, 2077 patients had begun treatment, and the last delivery was in April, 1957

Of these, 1039 had been told to take more salt 7 of them left the borough before delivery, 10 miscarried, and 3 were later found not to be pregnant Therefore 20 cases had to be discarded, leaving 1019 completed cases

TABLE II—PARITY OF PATIENTS

Group	Parity			
	0	1–3	4 or more	Total
S	144	720	155	1019
S—	146	695	159	1000

1038 other women had been told to take less salt 10 of them left the borough before delivery, 22 miscarried, and 6 were found later not to be pregnant Therefore 38 had to be discarded, leaving 1000 completed cases

The women in both groups were more or less similar in age (table I), parity (table II), and time of first attendance at the clinics (table III)

There were 38 cases of toxæmia in the 1019 patients in group S and 97 in the 1000 patients in group S— The number of toxæmias is shown in relation to parity in table IV and to the mother's age in table V The toxæmias were fewer in group S at all ages and parities Table VI shows the toxæmias in detail in both groups One patient in group S— had gross œdema of legs, hands, face, and abdomen, with headaches and vomiting

All the other patients who had had œdema were then collected, those with varicose veins being discarded The numbers of cases with œdema alone were 163 in group S, and 287 in group S— Œdema of the legs alone was present in 121 patients in group S and 206 patients in group S— Œdema of the hands, abdomen, and legs was present in 42 patients in group S and 81 patients in group S—

TABLE III—DATES OF FIRST ATTENDANCE

Group	First attendance at (wks)			
	0–20	21–30	31–40	Total
S	531	384	104	1019
S—	518	346	136	1000

Table VII shows the numbers of patients in both groups who had had toxæmia in a previous pregnancy, together with details of those who developed toxæmia again in their present pregnancy In group S there were 40 such patients, of whom 5 again developed toxæmia, and in group S— there were 39 such patients, of whom 13 again developed toxæmia

All the other abnormal conditions present in both groups are shown in table VIII The incidence of œdema, perinatal deaths, antepartum hæmorrhage, and bleeding during pregnancy was lower in group S than in group S— Whereas the incidence of postpartum hæmorrhage, prematurity, deformities, and breech delivery was almost the same in both groups 2 of the 17 cases of antepartum hæmorrhage in group S were due to placenta prævia, and 15 were diagnosed as accidental hæmorrhage by the obstetricians in the hospital 4 of the 32 cases in group S— were due to placenta prævia, and 28 were diagnosed as accidental hæmorrhage by the obstetricians in hospital

TABLE IV—TOXÆMIA IN RELATION TO PARITY

—	Parity			
	0	1–3	4 or more	Total
Group S				
Patients	144	720	155	1019
Toxæmias	16	18	4	38
Group S—				
Patients	146	695	159	1000
Toxæmias	38	51	8	97

The numbers of premature births in both groups were almost the same, and the range of birthweights was similar However, the maturity by dates was not the same, because 21 infants were born at less than thirty-four weeks, with 13 perinatal deaths, in group S—, and only 11 infants at less than thirty-four weeks, with 4 perinatal deaths, in group S

Table IX shows the stillbirths in detail The deformities were anencephalus, hydrocephalus and spina bifida, exomphalos, and fœtus papyraceus The perinatal deaths are the stillbirths plus the deaths of infants in the first week of life , they were fewer in group S than in group S— The neonatal deaths are deaths in the first twenty-eight days after birth, they are given in detail in table X The neonatal deaths were fewer in group S than in group S— The greatest difference lay in the respiratory syndrome, which was variously described in the necropsy reports as atelectasis, vernix membrane, hæmorrhagic pneumonia, and cold injury

TABLE V—TOXÆMIA IN RELATION TO MOTHER'S AGE

—	Mother's age (yr)

Toxæmias	10	54	28	5	97

During part of the investigation the placentas were weighed in 348 consecutive labours 176 placentas came from group S and 172 from group S— Twins were born to 6 women in group S and to 2 in group S— The twin placentas were discarded, leaving 170 placentas of single infants in each group The mean placental weight was 21 48 oz in group S and 20 90 oz in group S— Placental infarcts were found in 13 placentas in group S and in 32 placentas in group S—

cases of myeloid leukæmia (Minot 1922) For example, in the cases of polycythæmia, platelets in the circulating blood were found to be very numerous in only 3 cases, and in the cases of megakaryocytic myelosis they were only very numerous constantly in 1 patient, being normal in number in the others In the cases of osteosclerosis and myelosclerosis in which large numbers of giant cells were present in the tissues, though the platelets in the circulating blood varied from time to time they were mostly normal or somewhat fewer than usual

The giant cells were studied (Goldschmid and Isaac 1922), and the conclusion was reached that they are phagocytic and also formed platelets Needle-puncture aspiration of bone-marrow is an unsatisfactory method of examination in this type of case The megakaryocytes seem to be very fragile and often appear in groups, so they may miss being aspirated in any particular puncture This has been repeatedly proved in the present series, where only on very few occasions were large numbers of megakaryocytes present in a bone-marrow aspirate, though biopsy showed conspicuous giant-cell proliferation

Summary

An account is given of the blood-uric-acid levels of 58 patients with myeloid splenomegaly—17 with myeloid leukæmia, 10 with polycythæmia, and the remaining 31 with myeloid splenomegaly associated with osteosclerosis, myelosclerosis, megakaryocytic myelosis, and similar conditions

A high blood-uric-acid level was very closely associated with the presence of large numbers of megakaryocyte-like giant cells in the bone-marrow and spleen

Blood-uric acid levels may be used as a guide to the type of myeloid metaplasia present, and the gradual change between some of the conditions mentioned above —e g, from polycythæmia to megakaryocytic myelosis, and from megakaryocytic myelosis to myelosclerosis—may be followed by determining the blood-uric-acid levels

When a leukæmia-like disorder appears in a patient who has had gout for years, the histological changes in the bone-marrow and spleen are those of megakaryocytic myelosis

Prof J Patterson and his chief assistant Dr J Swale, of Charing Cross Hospital Medical School, were responsible for practically every blood-uric-acid estimation Most of the patients on whom these observations were made were under my own care at Charing Cross Hospital Dr E C Warner, Dr N S Plummer, Dr P B S Fowler, of Charing Cross Hospital, Sir Alun Rowlands, and Dr John Ellis, of the London Hospital, and Dr W A Bourne and Dr E C B Keat, of the Royal Sussex County Hospital, Brighton, kindly allowed me to study cases under their care I am most grateful to all for their help

SALT IN PREGNANCY

MARGARET ROBINSON
M D Belf, D P H

SENIOR ASSISTANT MEDICAL OFFICER, DERBY

IN pregnant rats the appetite for sodium chloride increases more than the appetite for calcium (Richter and Barelare 1938) In 1945, on the suggestion of Prof F G Young, and under the auspices of the *Medical* Research Council, the effect of salt on the cramps of pregnancy in women was investigated in St Thomas's Hospital, London The results *were published by* Robinson (1947) The conclusion was that salt cured the cramps of pregnancy in a large percentage of cases, and that there was little risk of producing toxæmia of pregnancy by giving salt to cure the cramps of pregnancy

At a later date 915 pregnant women with cramps were treated, and there was *no greater incidence of toxæmia* among them than among 2690 untreated women attending the antenatal clinics during the same period It was found, however, that most of the *patients who complained of* severe cramp also disliked salt This dislike of salt made it difficult to persuade all of them to take enough additional salt to cure their cramps

It was decided that it would be better to prevent the cramps, if possible, by getting women to take more salt early in pregnancy, but before doing this it was essential to find out whether extra salt in the diet of pregnant women did or did not increase the incidence of toxæmia of pregnancy The present investigation was begun on Aug 14, 1954, and the last patient was delivered in April, 1957

Method

Alternate patients, on their first examination at the clinics, were put into groups S and S— Group S were advised to take more salt in their diet—to use more salt in cooking, to add extra salt to their food at table, and to eat salt bacon, salt fish, and salted nuts, butter, &c Group S— were told to take less salt in their diet—to use as little salt as possible in cooking, to refrain from adding salt to their food at table, and to eat smoked bacon, unsalted butter, and unsalted fish, &c Otherwise the diets and other advice were the same in both groups At each visit their weight, blood-pressure, and urine tests were recorded, and they were reminded about their intake of salt according to their group Patients with a history of toxæmia were not excluded

Patients were considered to have toxæmia if their blood-pressure rose above 140/90 mm Hg with or without other symptoms They were also considered to have toxæmia if they had *œdema* and albuminuria without a rise in blood-pressure

At the first sign of toxæmia patients who had not booked a general practitioner were sent to hospital, where they were seen by an obstetrician who knew nothing of the patients' intake of salt He confirmed the diagnosis and admitted the patient to hospital for treatment On admission the intake of salt was stopped The liaison between the hospitals and the local-authority clinics is so close that it was possible for the investigator to follow the case-notes of each patient through to the end of the puerperium

All patients booked by general practitioners were sent home to bed The midwife in charge of the patient informed the general practitioner of what had been found and visited the patient at home about three times a week She kept a record of the patient's progress, and these

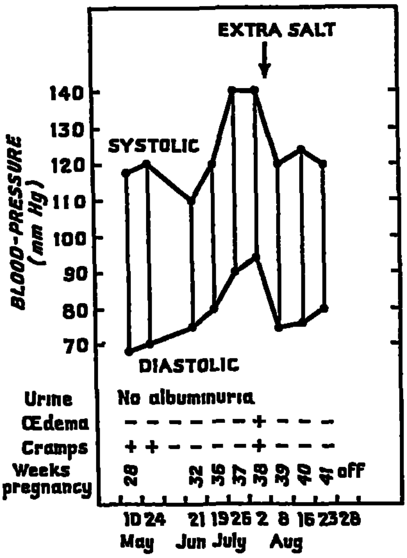

Fig 2—A mild case of toxæmia which cleared up completely

seen whether the symptoms disappeared or became worse

There were 28 women with toxæmia of pregnancy between the end of May and the end of September, 1957 8 of them had booked general practitioners and were not given extra salt but were referred, as usual, to their general practitioners, who either treated them at home or sent them to hospital These toxæmias followed the normal course and showed no sign of spontaneous recovery before delivery The other 20 patients had not booked a general practitioner and were advised to take extra salt This was their only treatment, they were not put to bed or told to rest, nor were they given sedatives

The 1st patient developed toxæmia at thirty-seven weeks' pregnancy She took more salt by adding as much salt as possible to her food Her symptoms had all disappeared in a week, and being better she spontaneously took less salt Next week her symptoms recurred She again took more salt and was again better in a week She then continued on her increased intake of salt until the end of her pregnancy and had no further symptoms of toxæmia (fig 1) This patient's weight again increased just before her blood-pressure rose, and returned to normal when she took more salt

The 2nd patient disliked salt and was put on six pills of sodium chloride a day Each pill contained gr 5, so she was taking gr 30 of sodium chloride daily Her blood-pressure never settled, it dropped to normal each afternoon and rose again every morning Her headache disappeared in twelve hours and never returned Her œdema went in four days and reappeared a few days later in her legs for a day Eight days after the onset of her toxæmia she was delivered of a normal full-time infant

A 3rd patient, who disliked salt, was put on twelve gr 5 pills of sodium chloride a day All her symptoms disappeared, but her blood-pressure never fell below 140/90 mm Hg, and on several days she had slight œdema of the legs only This patient and the 2nd patient were the only ones who had infarcted placentas

The remaining 16 patients were advised to measure out each morning four heaped teaspoonfuls of table salt and to see that by night they had taken all of it It was calculated that they took about gr 200–300 of sodium chloride daily The larger the amount taken the quicker was the recovery They found it easiest to take the bulk of this salt in orange-juice, lemonade, or lime-juice, the remainder being put on their food They were visited daily until all symptoms had disappeared All of them recovered completely and continued well on at least three heaped teaspoonfuls of table salt a day None of them had an infarcted placenta, and all gave birth to live full-term infants

In a 4th patient toxæmia developed about the thirtieth week of pregnancy She is 5-para with no history of previous toxæmia The blood-pressure rose first at the eighteenth week, and she was advised to take more salt At her next visit, her blood-pressure had dropped to normal, so she spontaneously cut off her extra salt This was not discovered until toxæmia developed at the twenty-ninth week She was then told to take three heaped large teaspoonfuls a day and recovered Her husband and two children developed influenza, and she was so busy nursing them and running the house that she had no time to measure out her daily salt As a result her blood-pressure again rose, but she had no recurrence of symptoms She was told that she could work as hard as she liked, provided she took four heaped teaspoonfuls of salt daily She again recovered, and was delivered, at forty-two weeks, of a living infant weighing 8 lb 6 oz , who cried lustily Macroscopically the placenta showed a few tiny patches of infarction round its edges

It was later found that large quantities of table salt often made the patients vomit Nausea and vomiting disappeared when they changed over to rock salt, but rock salt is more difficult to measure

It therefore appears that the 17 cases in group S were true toxæmias which recovered spontaneously because still more salt had been consumed after the symptoms had developed

Conclusion

Extra salt in the diet seems to be essential for the health of a pregnant woman, her fœtus, and the placenta

Summary

2077 pregnant women were investigated 1039 were told to take more salt and 1038 to take less salt

There was a lower incidence of toxæmia, œdema, perinatal death, antepartum hæmorrhage, and bleeding during pregnancy in those told to take more salt Other conditions were about the same in both groups Of those told to take extra salt 17 had transitory symptoms of toxæmia

20 women with early toxæmia were then treated with extra salt All of them improved, and the larger the dose of salt taken the quicker and more complete was the recovery The extra dose of salt had to be taken up to the time of delivery, otherwise the symptoms of toxæmia recurred Only early cases of toxæmia were available for treatment

My thanks are due to the Derby borough district midwives for their help in this investigation

Robinson, M (1947) *J Obstet Gynæc , Brit Emp* 54, 826

" Civil aviation enjoys a phenomenal safety record in comparison with that of the automobile, it being approximately forty times safer to fly on a scheduled airliner than to travel a like distance by auto But this wide variation would not exist if reasonable consideration had been given in earlier years to crash-safety design in automobiles If all automobiles were equipped with safety belts—and people wore them—adequate door locks to keep the occupants from cracking their skulls on the pavement, and delethalized interiors, the difference in the 'safety ratio' between airline and automobile travel would be reduced by at least one-half"—A HOWARD HASBROOK, *J Aviat Med* 1957, 28, 541

The mean weekly gain of weight was assessed in 844 patients who had attended the clinics regularly from less than twenty weeks' pregnancy to more than thirty-six weeks' pregnancy There were 422 cases in group S and 422 in group S— The mean weekly gain of weight was 0 95 lb in group S and 0 99 lb in group S—

In group S— some patients complained of severe backache, some of irritation of the skin of arms, legs, or abdomen, and some of weariness and stiffness in the limbs Others complained of falling because their legs suddenly gave way under them Sometimes this was so severe that they were afraid of going out of their houses or of crossing the road, in case they fell These symptoms did not develop in group S, and if they were present at the first examination they disappeared as soon as the women took more salt

TABLE VII—PREVIOUS TOXÆMIAS

Group	No	Recurrence	Raised B P	Alb	Raised B P Alb	Raised B P Œdema	Alb Œdema	Raised B P Alb Œdema
S	40	5	0	0	1	1	0	3
S—	39	13	2	1	1	5	0	4

Of all the cases diagnosed as toxæmia and sent to hospital only 2 were rejected as not being toxæmia The diagnosis of all the cases in group S— was confirmed by the hospital, and the patients were admitted for treatment The 2 cases rejected as not being toxæmia were in group S

The 1st case to be rejected was in a patient with a raised blood-pressure and no other symptoms of toxæmia She returned to the local-authority clinic and was encouraged to take still more salt, because it was thought that this would be sure to bring out her latent toxæmia A week later her blood-pressure had fallen to normal, and it remained down for the rest of her pregnancy No other symptoms of toxæmia developed, even though she kept up her increased intake of salt to the end

TABLE VIII—TOXÆMIAS AND OTHER ABNORMALITIES OF PREGNANCY

Group	No	Toxæmia	Perinatal deaths	A P H	Antenatal bleeding	Œdema	P P H	Premature births	Breech deliveries	Forceps deliveries	Cæsarean sections	Deformities
S	1019	38	27	17	27	163	47	86	23	22	9	25
S—	1000	97	50	32	50	287	50	89	29	19	14	22

After this case, all women, in both groups, with only a raised blood-pressure were watched for a week before being sent to hospital All such women in group S— had, by the end of the week, developed other signs of toxæmia and had to be sent to hospital, where the diagnosis was confirmed and they were admitted for treatment However, in group S, there were 4 women whose blood-pressure had dropped at the end of a week, no other signs of toxæmia developing They remained well throughout the remainder of their pregnancies

Meanwhile the 2nd case had been rejected by the hospital as not being a case of toxæmia

She had raised blood-pressure and albuminuria When seen at the local-authority clinic, she had been told to take still more salt in her food and to report at the hospital clinic almost a week later When she reported, her blood-pressure was normal and her urine clear She returned to the local-authority clinic and was advised to continue on her larger intake of salt She did so and remained well throughout the rest of her pregnancy

TABLE IX—STILLBIRTHS

Group	No	Grossly deformed	Apparently normal	Macerated	Fresh	Infarcted placentæ
S	20	7	13	4	9	4
S—	31	4	27	12	15	7

It was then realised that these transitory symptoms of toxæmia developed only in group S, and not at all in group S— It was thought that these symptoms might probably be due to the effect of the extra salt in the diet of these patients Since the symptoms were only transitory, it was decided that, in future, all women showing signs of toxæmia in group S would be told to take still more salt, and to report each week at the local-authority clinics In 11 cases the symptoms disappeared and never recurred throughout the remainder of the pregnancies Of these 11 patients 8 had raised blood-pressure and œdema, 2 had raised blood-pressure, albuminuria, and œdema, and 1 had albuminuria and œdema

TABLE X—NEONATAL DEATHS

Group	No	Deformities	Cerebral hæmorrhage	Respiratory syndrome	Fibrocystic disease
S	8	3	1	4	0
S—	21	4	2	14	1

When the investigation had ended and the data had been collected, the question arose what were these cases with transitory symptoms of toxæmia? Were they toxæmias which had spontaneously recovered, or were they not toxæmias at all? No similar cases had occurred in group S— Since it had been ultimately found that the incidence of toxæmia was much lower in group S than in group S—, it was difficult to believe that the extra salt in the diet had been the cause It was decided that, in future, women with toxæmia of pregnancy should be treated with extra salt in their diet Then it would be

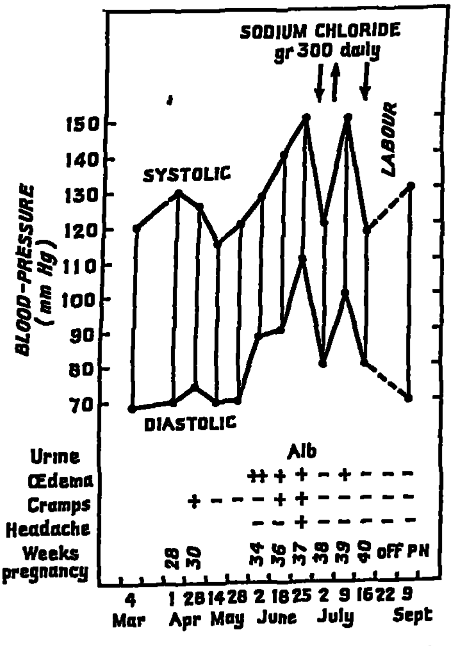

Fig 1—When salt was reduced (as indicated by the upward-pointing arrow) symptoms recurred They disappeared when salt was again increased (P N = postnatal)

walking, however, was still unsteady, she staggered and fell easily but did not stagger or fall in any particular direction She seemed to walk on rather a wide base. At the time of discharge there was no real evidence of any ataxia. Her coordination in general was slower and less harmonious than normal for her age but could be accepted as not incompatible with the degree of her mental impairment. Owing to the degree of mental impairment it had been impossible to apply adequately any finer test to ascertain or define the individual component factors in her incoordination

Previous history—The patient had been born at full term by normal delivery at home. There were no complications at birth The neonatal period was uneventful She was artificially fed and in the first few months had a moderate amount of vomiting, which led to a trial of many different brands of dried milk. She was eventually given sterilised cow's milk and from then on had no more vomiting In spite of the vomiting she had steadily gained weight. Her mother described her as a "lovely bonny happy baby" and did not consider that there had been any delay in smiling, sitting up, or walking (sat up at 8 months and walked at 11 months), but she felt quite early that the patient was backward like her brother (case 2), but only in speech. She had measles and chickenpox at the age of 1 year (case 2 and other sibs had the same illnesses at this time) Each illness was mild, and there were no unusual symptoms or complications She had a period of about a week's duration of convulsions in January, 1955 The convulsions were very slight ("just in and out" in her mother's words) They were symmetrical and generalised and occurred once or twice a day Her doctor (Dr J Edwards) prescribed sedation. Hospital advice was not sought. There was no known precipitating factor, and the child was apparently apyrexial throughout. For about 2 weeks after this the mother noticed that the patient was unsteady in her hand movements She did not think that there was any unsteadiness in walking or that the patient walked less well than before this 14-day period Thereafter until the time of her admission to hospital (Oct 29, 1955) her mother had not considered that there was any abnormality of coordination but after her discharge on Dec 8, 1955, her mother noticed that the patient walked unsteadily and fell easily She said that the child walked "sort of sideways", and that sometimes, even when standing, "her legs would just give way and down she would go" She did not notice any incoordination of the patient's upper limbs

Investigation and reports—The blood findings are given in table I The urine appeared normal on routine examination, no phenylpyruvic acid was found Mantoux negative. White-cell count normal with normal differential Blood-film normal, no punctate basophilia Throat swab no pathogens Lumbar puncture on Nov 3 and 22, 1955, clear fluid, pressure normal, cells less than 1 per c.mm, protein 20 mg per 100 ml Radiography of long bones, skull, and chest normal Urinary lead not abnormal Finally, on chromatography an unusual urinary aminoacid was found by one of us (V K. W) and was further studied at University College Hospital

TABLE I—BIOCHEMICAL FINDINGS IN SERUM (OR PLASMA) OF AFFECTED SIBS

—	Case 1			Case 2	
	Admission no				
	1	2	3	1	2

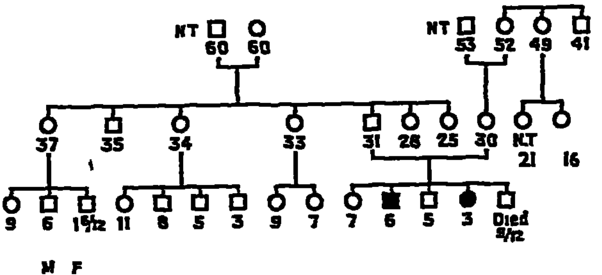

Fig 1—Family tree.

Patient's family—In view of the possibility that an inborn error of metabolism was responsible for the patient's disorder, her whole family were investigated, especially as regards their urinary output of aminoacids This was done thoroughly with the help of Dr H Harris The pedigree is shown in fig 1 The near relations were then interviewed. The father was a healthy lorry driver of average intelligence, the mother was a healthy woman of intelligence above average. Their children consisted of (1) V, a healthy intelligent girl aged 7 years, (2) K (case 2), a boy aged 6 years, who was healthy but attended a school for backward children, (3) C, a healthy intelligent boy aged 5 years, (4) M, and (5) D, a boy who died of bronchopneumonia at the age of $4^1/_2$ months The parents were not consanguineous There was no history of abortions or miscarriages The first four sibs were born at home and appeared normal at birth. The fifth child was given an exchange transfusion at the age of 4 hours for Rh (D) incompatibility After this he had cerebral manifestations in the presence of fairly deep jaundice but made an apparently satisfactory recovery A female cousin, aged 11 years, had had fits in infancy, but we have not seen or examined this child Otherwise there was no ascertainable history of mental defect, neurological disease, fits, or other possibly relevant factor in the family In view, however, of the mental defect in the second sib, K., and since his urinary aminoacid chromatogram showed a gross aminoaciduria abnormality identical with that already found in M, arrangements were made to admit both affected sibs to West Park Hospital, Macclesfield, for further study

Readmission—M. was admitted on Feb 15, 1956 Since Dec. 8, 1955, she had remained well The phenobarbitone had been discontinued a month before readmission, but there had been no further convulsions There was no ataxia Biochemical findings are shown in table I Intravenous pyelography showed that both kidneys excreted the dye normally No lesion of the urinary tract was found Blood picture normal Red-cell fragility normal Coombs test negative Urine normal on routine examination van den Bergh no direct reaction. Bilirubin less than 0·5 mg per 100 ml Thymol turbidity 3 units Thymol flocculation – Cerebrospinal fluid (C.S.F) clear, colourless, and containing no cells, sugar 75 mg per 100 ml, chlorides 770 mg per 100 ml, and protein 10 mg per 100 ml. Pandy negative Lange gold showed no change.

Electrocardiography—On Nov 29, 1956, Dr A Hollman reported "Semi-vertical heart with ST depression in V4, aVL, and I, and T-wave inversion in V7, aVF, and III R/S rate of 0·30 in lead V1 is rather low but is borderline normal for age The changes are consistent with left ventricular hypertrophy"

Electroencephalography—The resting record showed spasmodic bursts of medium-voltage alpha rhythm at 8 c/s in the occipital and preoccipital areas, bilaterally synchronous and symmetrical The dominant rhythm was of medium-voltage theta activity at 4–6 c/s seen in all areas, symmetrical, and bilaterally synchronous There were occasional diffuse bursts of high-voltage delta activity at $3^1/_2$–4 c/s, which were symmetrical and predominantly out of phase on the right Low-voltage beta

A DISEASE, PROBABLY HEREDITARY, CHARACTERISED BY SEVERE MENTAL DEFICIENCY AND A CONSTANT GROSS ABNORMALITY OF AMINOACID METABOLISM

There is no need to stress the problems posed by the large numbers of mentally defective people, and by our few present hopes of fully corrective therapy A milestone in the modern development of our knowledge occurred with the discovery of the specific hereditary form of mental deficiency called phenylketonuria (Folling 1934), especially because of its association with a comparatively simple disorder of phenylalanine metabolism—simple, that is, when compared with the complexity of the biochemistry in other hereditary forms of mental deficiency such as Tay-Sachs disease, or gargoylism Since that time further discoveries have been made of more simple biochemical disorders in various forms of mental deficiency and in closely related neurological or medical conditions for instance, galactosæmia (reviewed by Holzel et al 1957), Wilson's disease (reviewed by Bearn 1957), the so-called "organic aciduria" syndrome (Lowe et al 1952, Dent and Harris 1956), and recently of H-disease (Baron et al 1956), and of goitrous cretinism (reviewed by Stanbury and McGirr 1957)

In each of these instances compounds of well-known chemical structure are involved Since something is already known about their metabolism, one can immediately speculate about possible forms of therapy and, in some cases—e g, phenylketonuria and Wilson's disease—begin seemingly rational therapeutic trials A further point of interest is the fact that the biochemical disorder, when known, may be so gross, easy to detect, and constantly present as to remove any difficulty in diagnosis

It also seems to be of especial significance that all the disorders mentioned above are hereditary Clearly there are likely to be many more such diseases which have so far escaped recognition, but with the development of paper chromatography, by which body fluids can easily be scanned for the presence of abnormal quantities of hundreds of known or likely metabolites, we can reasonably expect many important discoveries to be made in the near future

We describe here preliminary studies of a further disease of this type These studies began in October, 1955, when a girl apparently suffering from idiopathic epilepsy was admitted under one of us (J D A) Her subsequent progress did not conform to the usual pattern of such epilepsy After the cessation of the convulsive period, and in the absence of further convulsive episodes, she exhibited general ataxia This unusual feature, with the fact that the child was severely mentally retarded, and our subsequent failure to establish an organic neurological cause or systemic disease, suggested a metabolic disorder such as hypercalcæmia or lead poisoning Chromatography (V K W) then revealed the presence of a gross abnormality of urinary aminoacids Study of the girl's relations later revealed that an identical abnormality was present in a male sib who also has a severe mental defect

Case-reports

Case 1 —A girl, M, aged 3 years 5 months, was admitted to Stepping Hill Hospital, Stockport, as an emergency on the evening of Oct 29, 1955 She was conscious but not cooperative and was considered to be recovering from convulsions She had been quite well up to mid-morning of that day, but between then and admission she had had five convulsive seizures of increasing severity and duration, the last shortly before admission In each she had been unconscious, but in none had she been incontinent From the description it appeared that there had been symmetrical generalised clonic movements of face, arms, and legs The first attack had lasted 2 or 3 minutes, and the last 15–20 minutes There was nothing to suggest a precipitating cause, she was apyrexial, and there was no history of injury

General examination, apart from a moderately loud (grade-3) musical systolic murmur, maximal along the left sternal border, was negative Examination of the nervous system revealed no abnormality except that the Babinski reflex on each side was equivocal

Treatment and progress —She was placed on routine sedation (phenobarbitone), the provisional diagnosis being idiopathic epilepsy During the night she had one further convulsion, of a generalised epileptiform type, lasting a few minutes In the morning she seemed brighter She continued apyrexial but had developed purulent rhinorrhœa, and her fauces were thought to be injected Prophylactic parenteral penicillin was given and continued for the next five days The plantar response after admission became flexor bilaterally Four days after admission (Nov 2, 1955) at short intervals *(1 hour)* during the morning there were three further similar convulsions The patient was then still apyrexial There were no more convulsions thereafter during her stay in hospital (discharged Dec 9, 1955) During this time she was maintained on phenobarbitone, and she was discharged on prophylactic doses On Nov 16, 1955, she had pyrexia *(100 5° F)* for the first time, it lasted 5 days, the highest recorded temperature being 102 4°F and was considered to be due to an *Escherichia coli* pyelitis and was treated with sulphadiazine

Mental condition —Though, for a day or two after admission, we had been inclined to attribute her failure to speak and cooperate in general to a combination of her new environment and the effect of the epileptiform seizures, we realised at this time that she had a severe degree of mental retardation On the sixth day after admission (Nov 4, 1955) she had severe ataxia (she had had three convulsions on Nov 2, 1955) Ataxia was first seen in her arms, being particularly noticeable during attempts to pick up a cup and feed herself The degree of incoordination was such that she could not complete these simple movements and had to be fed, but she had no difficulty in swallowing and no choking There was no apparent anomaly of any cranial nerve, in particular no nystagmus The incoordination resembled that of a severe chorea, with a suggestion of an athetoid overlay, and occurred only on voluntary action Both arms were equally affected We could not examine the coordination of her legs other than to establish that she could not stand or walk Tone was normal From this day on, there was a steady, quite rapid, and general diminution in the degree of incoordination By Nov 15, 1955, she could coordinate fairly well she could feed herself and walk Her

TABLE II—BLOOD-GROUPS

Father	Mother	Case 2	Case 1	Brother	Sister
O	O	O	O	O	O
R_1r	rr	R_1r	R_1r	rr	rr
MNs	MNs	MNs	MNs	MNs	MNs
P−ve	P−ve	P−ve	P−ve	P−ve	P−ve
Le(a+b−)	Le(a−b−)	Le(a−b−)	Le(a−b−)	Le(a−b−)	Le(a+b−)
Lu(a−)	Lu(a−)	Lu(a−)	Lu(a−)	Lu(a−)	Lu(a−)
kk	K+ve	K+ve	K+ve	kk	kk
Fy(a+)	Fy(a+)	Fy(a+)	Fy(a+)	Fy(a+)	Fy(a+)
Jk(a+)	Jk(a+)	Jk(a+)	Jk(a+)	Jk(a+)	Jk(a+)

Our final opinion of coordination in these two children was that in each there was some slowness and slight clumsiness in the general execution of movement, the degree of which, however, we did not consider to be incompatible with the respective degree of mental impairment

Intellect

The severity of the intellectual impairment in each case was confirmed by the I Q rating (Dr R Cargill) case 1's Gesell rating was 32, and case 2's intelligence quotient on the Terman-Merrill scale was 50 Case 1 had a vocabulary of about 12 words, but case 2 had about 50 words Case 1's perception seemed to be of a higher standard than her execution Each child was docile, and there did not appear to be any emotional disturbance in either

Cardiovascular System

The murmur heard in each child was similar in location, character, and intensity Clinical examination of the heart in each case revealed no other abnormality, and this was confirmed radiologically It is thought possible that each child has an interventricular septal defect

a *b*

Fig 3—Standard urine aminoacid chromatograms *a* case 1, *b*, case 2.

Note extraordinary similarity between these two affected sibs and great difference from published normals (Dent and Walshe 1954) In each chromatogram the strongest spot is the unknown aminoacid and the weak spot above and slightly to the left of it is the substance to which it can be readily converted by hydrolysis

Blood-groups

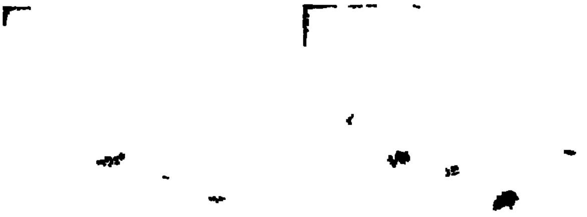
We are indebted to Dr F Stratton for determining the blood-groups (table II) It is presumably a chance finding that the two sibs have identical phenotypes

Alkaline Phosphatase

In each child the level of alkaline phosphatase, on each occasion on which it was estimated, was moderately high We cannot offer any explanation of this Though it was established in the mother's third and fourth pregnancies (fig 1) that there were then no maternal antibodies which might produce fœtal kernicterus, the ataxia seen in case 1 and the type of ambulation in case 2 in infancy might in each instance have been caused by abnormality of the basal nuclei Liver function, assessed by our empirical tests, was not disturbed, but, since a high alkaline-phosphatase level may be a sign of liver disease, further attention should perhaps be given to this abnormality

Urinary Excretion of Aminoacids

Since the discovery, in the urine of both case 1 and case 2, of a grossly abnormal aminoacid excretion, which was not present in the urine of other members of their family, repeated analyses of further samples of their urine have confirmed the original findings The abnormality appears to be constant qualitatively and quantitatively in both children The nature of this may be seen from fig 3 It will be noted that it mainly comprises the excretion of a large amount of one ninhydrin-reacting substance,* but there is a small amount of another substance close to it on the chromatogram Neither of these can be matched in their chromatographic behaviour with any of the known aminoacids in our very large collection of these compounds, or with any of our catalogued "unknowns" such as have been found, for instance, as a result of detailed studies of normal urinary constituents by Westall (1955) It is also remarkable that the aminoacids normally excreted—e g, glycine, alanine and taurine—are, if anything, excreted in this urine in smaller quantities than usual

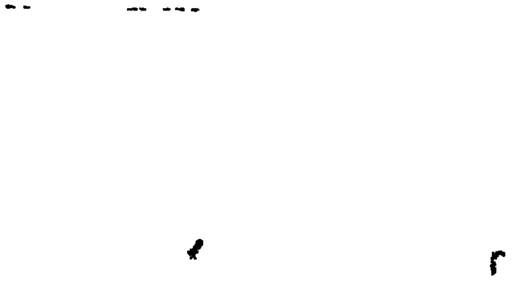


a *b*

Fig 4—Standard aminoacid chromatographs of plasma: *a*, case 1, *b*, case 2

The weak spot low down on the right in both cases is the unknown aminoacid Immediately above it is a strong spot due to glutamic acid This spot is unusually strong owing to its formation from glutamine during storage of the specimen The other aminoacids present are otherwise quite normal

We cannot yet suggest any chemical structure for the main urinary constituent It has not so far reacted with reagents which we have tried for specific chemical groupings—e g, indole, glyoxaline, and ester phosphate—or with tests likely to reveal dicovalent sulphur The main spot is very easily hydrolysed to the subsidiary spot (also unidentified) which appears weakly immediately above and to the left of it on the urine and C S F chromatograms (figs 3 and 5) The change goes virtually to completion in 5 *N* hydrochloric acid at 100°C



a *b*

Fig 5—Standard aminoacid chromatograms from C.S F *a*, case 1, *b* case 2.

These are quite normal except for the large strong spot low down to the right which is due to the unknown aminoacid Note how much stronger this substance is here than in the plasma Equal volumes of C S F and plasma were analysed on these chromatograms activity at 18–22 c/s underlay the record and was superimposed upon the slower components The record was abnormal It showed cerebral dysrhythmia, which was predominantly in the right hemisphere No typical epileptic features were seen

---

* Further work on the identification of the unknown ninhydrin-reacting substance in the urine of the two affected sibs suggests strongly that it is not (as we have assumed above) a single aminoacid but a peptide which is rather resistant to acid hydrolysis

Discharge —The patient left hospital on Aug 10, 1956

Readmission —The patient was readmitted for a week from Jan 17 to 24, 1957, to University College Hospital Since her previous admission she had had no further fits and in her general health had remained well No further signs of disease were noted The cardiac murmur was still present The blood-pressure was 95/70 mm Hg The biochemical findings are given in table I Routine urine and renal-function tests gave normal results Skeletal radiographs were normal

Case 2 —M 's elder brother K , aged 6 years 3 months, was admitted on Feb 15, to West Park Hospital and discharged on Aug 10, 1956 He had been born at full term by normal delivery at home There were no complications at birth The neonatal period was uneventful He was fed on dried milk and throve well but was never an eager feeder He smiled at 5 months, sat up at 7 months, and walked at 13 months His mother did not consider that he was backward in anything except speech This delay in speaking she attributed to deafness, but she had him examined at the age of $2^1/_2$ years at Manchester Royal Infirmary by Professor Ewing, who excluded any auditory abnormality From then she had accepted the patient as backward He had never had any fits, and his only previous illnesses had been measles and chickenpox at the age of 4 years at the same time as case 1 and their sibs These illnesses were mild and uncomplicated He had sustained one accident at the age of 4 years 9 months he was knocked down by a car, was not unconscious, and sustained only minor injuries He was treated at home His mother said that he had never had any unsteadiness like M but " seemed to keep his legs a bit bent at the knees and to take quicker and quicker steps as he went forward, often ending in falling forward "

Examination —General examination was negative except that, like M , he had a moderate (grade-3) musical systolic murmur maximal along the left sternal border The continuing severe mental retardation was noted It was also observed, as in case 1, that the hair was abnormal (see below)

Investigations —Biochemical findings are given in table I Skeletal radiography, screen of heart, and intravenous pyelography normal Full blood-count normal Red-cell fragility and Coombs test normal Routine examination of urine normal van den Bergh no direct reaction Serum-bilirubin less than 0 5 mg per 100 ml Thymol turbidity 2 units Thymol flocculation negative C S F clear and colourless, containing no cells, sugar 75 mg per 100 ml , chloride 750 mg per 100 ml , and protein 10 mg per 100 ml Pandy negative Lange gold test normal

Electrocardiography —On Nov 29, 1956, Dr Hollman reported " There is a dominant R in V1 with an R/S ratio of between 1 7 and 2 5, which is definitely abnormal at this age and consistent with right ventricular hypertrophy There is also slight ST depression in aVL, which may indicate left ventricular involvement The QTC is prolonged at 0 440 "

Electroencephalography —The resting record shows spasmodic bursts of high-voltage alpha rhythm at 8 c/s in the occipital areas There were occasional bursts of low-voltage or medium-voltage beta activity at 18–20 c/s in all areas High voltage theta activity was the dominant rhythm at 4–6 c/s in all areas Associated with this were occasional high-voltage spikes, which are out of phase throughout the right hemisphere There were numerous bursts of diffuse high-voltage spike and wave activity at 3–$3^1/_2$ c/s They were symmetrical and consistently out of phase on the right The record was abnormal There was definite evidence of epilepsy dominating the right hemisphere, with occasional spread to the left

Readmission —The patient was readmitted for a week from Jan 17 to Jan 24, 1957, to University College Hospital Since his previous admission he had had no fits and had been in good general health No further signs of disease were noted The cardiac murmur was still present The blood-pressure was 110/70 mm Hg His hair had grown a little better and required occasional cutting The biochemical findings are given in table I Routine urine and renal-function tests gave normal results Skeletal radiographs were normal

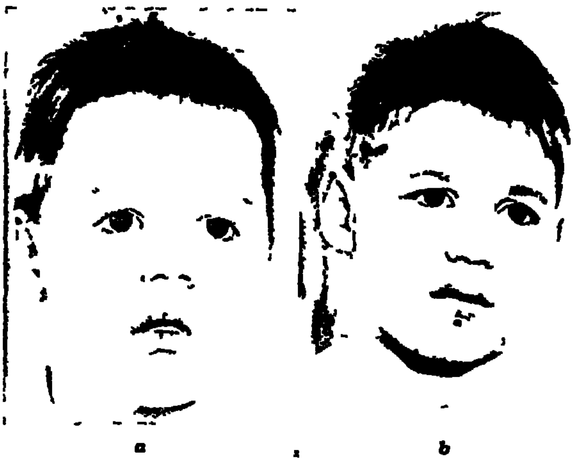


Fig 2—The affected sibs *a*, case 1 (M); *b*, case 2 (K)

Further Observations on the Two Affected Sibs

Facial Appearance

The affected sibs bore a striking resemblance to each other (fig 2) Their expression also was the same, being sad and wistful

Hair

Their hair was light brown, dry, and friable Its growth seemed to be irregular, giving a tufted, almost matted, appearance It was difficult to comb or brush into any semblance of tidiness The ends were frayed and they seemed to break off abnormally easily, particularly over the occipital region, presumably owing to its being the area of greatest friction

Their mother had noticed that their hair was not *like that* of the other two living sibs She described it as " different—goes very brittle—comes out on the comb and leaves a stubble " She thought the " coming out " was particularly noticeable in November and December She stated, however, that K had " beautiful curly " hair until the age of 15 months, and that case 1's hair also was normal in infancy The hair of the father, mother, and the other two living sibs *was normal* (for colour of hair see below)

Skin

M 's skin was slightly rough on the arms and on the dorsum of the hands but elsewhere normal The texture of case 2's skin was normal In both children perspiration appeared to be normal Except that case 2 had an area of pigmentation near the lower half of his right sternomastoid muscle and as large as a silver threepenny piece, there were no other lesions (xanthomatous, vascular, pigmentary, or other) in either child The teeth and nails were normal Lacrimation and salivation were normal Case 1's eyes were grey and case 2's light brown

Electroencephalography and Neurology

In both children the electroencephalograms were grossly abnormal (see above) Case 2, whose electroencephalograms showed definite evidence of epilepsy, had no clinical manifestations, whereas case 1, in whose electroencephalograms " no typical epileptic features were seen ", had epileptiform seizures We are indebted to Dr C E Smyth for the electroencephalograms and for his further neurological opinion as follows " So far as I am concerned, I could find no evidence of gross cerebral disease in either of them They are, of course, backward There is no evidence of any motor disturbance, and I thought their fundi were normal There were no superficial anomalies of the skin and no enlargement of liver and spleen I cannot really throw further light on this problem " disease cannot be normally dealt with If this is so, its normal concentration in the body must be exceedingly low because it does not seem to have been found before by other workers studying brain extracts or biological fluids, and was not even found by Westall (1955) in his very detailed study of the aminoacid composition of normal urine, a study based on an analysis by micro methods of concentrates from 100 litres of normal urine

It is intriguing to consider the strong possibility that an organic cardiac lesion also exists and is related to the biochemical abnormality With the discovery of serotonin (5-hydroxytryptamine) and of the cardiac lesions associated with its overproduction by argentaffinomata (Sjoerdsma et al 1956) the stage is set for the association of further cardiac lesions with other humoral factors

Our further consideration of the cause of the disease and of its possible treatment must await identification of the unknown substance The disease is certainly extremely rare because, apart from the fact that we and others have never observed it in the course of many thousand chromatographic examinations of urine, a deliberate search for the condition among 1500 mentally defective patients has so far failed to reveal a further case (H Harris, private communication) This search is being continued

Summary

A family is described in which two of four children of unrelated parents show a severe degree of mental retardation

Both affected sibs have grossly abnormal electroencephalograms One has had several epileptiform convulsions followed by ataxia of a few days' duration Both sibs have friable hair and systolic murmurs but are otherwise healthy and normal on physical examination

The two affected sibs have an identical and highly specific gross disorder of aminoacid metabolism not present in any other members of the family This is most easily shown by the constant excretion in their urine of large quantities of a new and still unidentified substance There are also minor changes in the pattern of the aminoacids excreted

The abnormal substance was found in low concentrations in the plasma of the affected children but was present in very much higher concentration in their C S F It seems possible that it is formed in the brain or in some other organ in close association with the C S F, whence it leaks out into the plasma and is rapidly excreted by the kidneys

Apart from acknowledgments already made in the text, we wish to thank also Miss V Ward for technical assistance and Miss B Warland for help with the family survey

MANCHESTER ROYAL INFIRMARY

OUR small trial of the treatment of chronic asthma with aerosol hydrocortisone proved disappointing (Brockbank et al 1956) Better results have been obtained in a blind trial of hydrocortisone and prednisolone powder inhalations The manufacturers kindly provided us with hydrocortisone ('Cortef'), a much smaller supply of prednisolone ('Delta Cortef'), and an undetectable blank inert powder consisting of lactose and 1% calcium stearate, all in sausage-shaped capsules, for use in a special inhaler

Method

The materials were placed in numbered bottles in random order by a member of the staff of the Department of Medicine and were used in number sequence on patients whom we considered to be suitable for trial These all had chronic asthma and used much antispasmodic material They were seen by us at least a week before they were included in the trial and were not improving spontaneously during this period When the trial was completed, we assessed each case and reported to our colleague and learnt for the first time what had been in each bottle

Each patient was provided with fourteen capsules, which needed pricking with a pin at one end before use The capsule was then inserted in the inhaler, pinhole uppermost Sharp pressure on the rubber bulb jerked the capsule upwards until its progress was checked, thus expelling a surprising amount of powder

The patient was instructed to use the inhaler thrice daily irrespective of spasm On each occasion the bulb was to be given three good sharp squeezes, holding the inhaler upright in the mouth and breathing in at the critical moment Care had to be taken not to breathe out into the inhaler, otherwise the moisture caused the powder to clog

When the capsule was half empty it was taken out, and the top half was removed The inhaler and capsule had then to be kept upright, or the powder spilled out One capsule lasted on average five days The period of treatment was about seventy days and was followed by a month without any of the powder inhalation

Patients were instructed to use their own antispasmodic material as required, but in successful ("much improved") cases the need for this vanished They were also asked to keep a diary of the number of attacks of spasm and the amount and type of antispasmodic material required during the trial

Each hydrocortisone capsule contained 15 mg of the acetate (equivalent to 13 4 mg of hydrocortisone base), making the daily dose 3 mg Each prednisolone capsule contained 5 mg, making the daily dose 1 mg

TABLE I—ANALYSIS OF MATERIAL

Treatment	No and sex of patients	Age (yr)	Duration of asthma (yr)
Hydrocortisone	24 (8M 16F)	16–63 (av 42)	0 5–45 (av 13)
Prednisolone	7 (3M 4F)	26–57 (av 44)	3–30 (av 13)
Blank	13 (6M 7F)	25–66 (av 45 5)	3–32 (av 14)
Total	44 (17M 27F)	16–66 (av 43)	0 5–45 (av 13)

in 15 minutes. If the urine is not fresh, at least two further unidentified ninhydrin-reacting spots are seen on the chromatogram in addition to the main spot, these also being presumably decomposition products of the main spot. The production of one of these further spots also appears to occur on electrolytic desalting of the urine. A large stock of these compounds in the crude state has been isolated from the urine for identification.

Chromatograms of the plasma and C.S.F. were also prepared according to our standard methods (Dent 1951) and are shown in fig. 4. The low plasma concentration of the unknown spot occurring in the presence of a very high urinary output suggested a high renal clearance and was confirmed for case 2 by determining his renal aminoacid clearances in a fasting 3-hr. urine collection and collections of blood at 1 and 2 hr. pooled before being analysed by the Moore and Stein (1954) method. The clearance of the unknown spot was 105 ml. per min. per 1.73 m.^{2}, suggesting that little or none of the compound is reabsorbed by the renal tubules. If its molecular weight is 150 and it reacts with ninhydrin to give the same colour as does leucine, the plasma level of the unknown compound was 1.7 mg. per 100 ml. and the average urine output over the 3-hr. period was 1.8 mg. per min. per 1.73 m.^{2}, corresponding to a 24-hr. fasting excretion of about 2.5 g. per 1.73 m.^{2} or an actual uncorrected output of 1.3 g. in case 2. The high C.S.F. level seen on the paper chromatograms was fully confirmed on Moore and Stein analysis, which gave values of 4.2 and 5.1 mg. per 100 ml. for cases 1 and 2 on the same assumptions as stated above, this being 2.5–2.9 times higher than the plasma level. No other aminoacid concentrations, excretions, or clearances were disordered to any comparable extent.

Head Size

Prof. L. S. Penrose reported as follows:

Case 1, aged 4 years: length 131 mm., breadth 168 mm. Norms for female aged 4 years are 134 mm. and 169 mm. respectively.

Case 2, aged 7 years: length 135 mm., breadth 175 mm. Norms for male aged 7 years are 141 mm. and 179 mm. respectively.

Both children have normally shaped heads but with dimensions below the average. In neither case is the deviation sufficient to be classed as abnormal, but in case 2 it is borderline.

Hair Colour

Specimens of hair from parents and four children were examined, and the reflection of light over the range of the visible spectrum was measured by Dr. N. A. Barnicot, who reported as follows:

"As is usual, the four children have hair of lighter shade than that of their parents because of the normal tendency for hair to darken with advancing age. There is no apparent tendency for the affected children's hair to be lighter in colour than that of their normal sibs. One specimen of case 1's hair, taken on Dec. 5, 1956, seems to be of rather brittle texture, but it is difficult to demonstrate this unequivocally, and specimens taken since then seem normal."

Discussion

The clinical aspects of this form of mental deficiency have nothing particularly characteristic about them. This will make clinical detection of further cases rather difficult, especially in the first year of life, during which they had appeared to develop normally. The unusual behaviour of M. after her epileptic seizures is perhaps not so surprising in view of her very severe mental deficiency. Presumably disturbances produced by epilepsy are much more severe when cerebral function is already grossly subnormal. The excessive friability of the hair was certainly unusual. The friability was somewhat variable, for M., when first seen, had a short crop of hair which did not need cutting and did not for some time grow longer. A year later it had grown better and was a few inches longer in places. There were no other ectodermal abnormalities that we could discover.

The fact that the two sibs were so similarly affected is of great importance, and it will be necessary in future to confirm that this means, as we think very likely at the moment, that the disease is hereditary. We could not discover any possible environmental factors that might have been operative, and rhesus incompatibility was adequately excluded. The fifth sib required an exchange blood-transfusion at birth because of hæmolytic disease. However, no antibodies were found when the mother had been examined during the third and fourth pregnancies and they did not appear till the end of the fifth pregnancy.

The discovered biochemical abnormality was quite spectacular. The unknown substance was found in all specimens of urine of cases 1 and 2 that were examined; all the other members of the family had normal aminoacid patterns shown by paper chromatography. These all-or-none findings argue in favour of a genetic causation. The unknown substance was excreted in very large quantity, and the other aminoacids normally excreted in urine were present, if anything, in smaller quantities than usual (fig. 3).

Our analyses of the C.S.F. and of the plasma of cases 1 and 2 are especially interesting. In healthy people the aminoacids that are present in the plasma are all present in the C.S.F. in greatly reduced concentrations, except glutamine, which is present in about the same concentration. In phenylketonuria, in which the biochemical abnormality—namely, inability to metabolise phenylalanine—is present in the liver, phenylalanine accumulates in the plasma and is thereupon excreted into the urine by an overflow mechanism, and it leaks also into the C.S.F. to reach a concentration of about a third of that in the plasma. In the disease we have here described the situation is entirely different. As can be seen from the paper chromatograms, and confirmed by quantitative analysis, the C.S.F. concentration of the unidentified aminoacid (fig. 5) is much higher than in the plasma (fig. 4), about 2.5–2.9 times or so as high. This suggests at once that the substance is formed not by a defective enzyme in the liver or in any other organ in close relationship to the systemic blood-supply but in the brain or in some other structure closely associated with the C.S.F. It leaks, presumably, from there into the blood-stream, whence it is rapidly excreted by the kidney into the urine, probably without any tubular reabsorption. This latter situation seems to occur when other presumed purely intracellular substances find their way into the plasma, which they do not normally use as a means of transport. Examples of such compounds are phosphoethanolamine (our unpublished results on the study of hypophosphatasia), homogentisic acid (Neuberger et al. 1947), β-aminoisobutyric acid, at least in high excretors of this substance (Evered 1956), and porphobilinogen (Goldberg and Rimington 1954). The mechanism of excretion in such cases is not fully described in terms of the definitions previously made of "renal" and "overflow" mechanisms (Dent and Walshe 1954). Perhaps it should be called a "no-threshold" aminoaciduria.

Our present speculation is therefore that the disease has revealed for us a substance which is normally produced by and metabolised in the brain but which in this disease cannot be normally dealt with. If this is so, its normal concentration in the body must be exceedingly low because it does not seem to have been found before by other workers studying brain extracts or biological fluids, and was not even found by Westall (1955) in his very detailed study of the aminoacid composition of normal urine, a study based on an analysis by micro methods of concentrates from 100 litres of normal urine.

It is intriguing to consider the strong possibility that an organic cardiac lesion also exists and is related to the biochemical abnormality. With the discovery of serotonin (5-hydroxytryptamine) and of the cardiac lesions associated with its overproduction by argentaffinomata (Sjoerdsma et al. 1956) the stage is set for the association of further cardiac lesions with other humoral factors.

Our further consideration of the cause of the disease and of its possible treatment must await identification of the unknown substance. The disease is certainly extremely rare because, apart from the fact that we and others have never observed it in the course of many thousand chromatographic examinations of urine, a deliberate search for the condition among 1500 mentally defective patients has so far failed to reveal a further case (H. Harris, private communication). This search is being continued.

Summary

A family is described in which two of four children of unrelated parents show a severe degree of mental retardation.

Both affected sibs have grossly abnormal electroencephalograms. One has had several epileptiform convulsions followed by ataxia of a few days' duration. Both sibs have friable hair and systolic murmurs but are otherwise healthy and normal on physical examination.

The two affected sibs have an identical and highly specific gross disorder of aminoacid metabolism not present in any other members of the family. This is most easily shown by the constant excretion in their urine of large quantities of a new and still unidentified substance. There are also minor changes in the pattern of the aminoacids excreted.

The abnormal substance was found in low concentrations in the plasma of the affected children but was present in very much higher concentration in their C.S.F. It seems possible that it is formed in the brain or in some other organ in close association with the C.S.F., whence it leaks out into the plasma and is rapidly excreted by the kidneys.

Apart from acknowledgments already made in the text, we wish to thank also Miss V. Ward for technical assistance and Miss B. Warland for help with the family survey.

OUR small trial of the treatment of chronic asthma with aerosol hydrocortisone proved disappointing (Brockbank et al. 1956). Better results have been obtained in a blind trial of hydrocortisone and prednisolone powder inhalations. The manufacturers kindly provided us with hydrocortisone ('Cortef'), a much smaller supply of prednisolone ('Delta Cortef'), and an undetectable blank inert powder consisting of lactose and 1% calcium stearate, all in sausage-shaped capsules, for use in a special inhaler.

Method

The materials were placed in numbered bottles in random order by a member of the staff of the Department of Medicine and were used in number sequence on patients whom we considered to be suitable for trial. These all had chronic asthma and used much antispasmodic material. They were seen by us at least a week before they were included in the trial and were not improving spontaneously during this period. When the trial was completed, we assessed each case and reported to our colleague and learnt for the first time what had been in each bottle.

Each patient was provided with fourteen capsules, which needed pricking with a pin at one end before use. The capsule was then inserted in the inhaler, pinhole uppermost. Sharp pressure on the rubber bulb jerked the capsule upwards until its progress was checked, thus expelling a surprising amount of powder.

The patient was instructed to use the inhaler thrice daily irrespective of spasm. On each occasion the bulb was to be given three good sharp squeezes, holding the inhaler upright in the mouth and breathing in at the critical moment. Care had to be taken not to breathe out into the inhaler, otherwise the moisture caused the powder to clog.

When the capsule was half empty it was taken out, and the top half was removed. The inhaler and capsule had then to be kept upright, or the powder spilled out. One capsule lasted on average five days. The period of treatment was about seventy days and was followed by a month without any of the powder inhalation.

Patients were instructed to use their own antispasmodic material as required, but in successful ("much improved") cases the need for this vanished. They were also asked to keep a diary of the number of attacks of spasm and the amount and type of antispasmodic material required during the trial.

Each hydrocortisone capsule contained 15 mg. of the acetate (equivalent to 13.4 mg. of hydrocortisone base), making the daily dose 3 mg. Each prednisolone capsule contained 5 mg., making the daily dose 1 mg.

TABLE I—ANALYSIS OF MATERIAL

Treatment	No. and sex of patients	Age (yr.)	Duration of asthma (yr.)
Hydrocortisone	24 (8M., 16F)	16–63 (av. 42)	0.5–45 (av. 13)
Prednisolone	7 (3M., 4F)	26–57 (av. 44)	3–30 (av. 13)
Blank	13 (6M., 7F)	25–66 (av. 45.5)	3–32 (av. 14)
Total	44 (17M., 27F)	16–66 (av. 43)	0.5–45 (av. 13)

TABLE II—CLASSIFIED RESULTS

Result	Hydrocortisone	Prednisolone	Blank
Much improved	13	1	2
Improved	4	—	3
No better	7	6	8
Total	24	7	13

Progress was assessed according to the lessening of attacks in duration and frequency, the lessening of the need for antispasmodic material, and the improvement in health and mobility. The dosage was so small that no side-effects of steroid therapy arose.

Results

The details of our patients are shown in table I. Our results are shown in table II. The cases treated with hydrocortisone are analysed in table III. The details of the successful cases do not materially differ from those of the unsuccessful, the patients tended to be a little younger but more chronic.

The duration of the remissions was precisely similar for the much improved and improved groups, varying from two weeks to four months (average six weeks). 5 patients returned to hydrocortisone inhalations—3 with improvement, 2 without. These latter thought that the material obtained from the chemist was not the same as we had provided.

To assess our results statistically we grouped the much improved and the improved cases together and compared them with the number of failures.

It appears that the hydrocortisone produces significant benefit, the probability that results as good as these should have occurred by chance alone is only 0.028. The number of patients treated with prednisolone is too small to lead to firm conclusions. There is no evidence of improvement over the placebo, but the results are significantly inferior to the hydrocortisone (P=0.029).

Discussion

The dosage of hydrocortisone acetate given by inhalation in our patients was so small that the beneficial effects must have resulted from a local action on the bronchial tree and not to a systemic effect after absorption. This action is presumably similar to that of steroids applied topically in skin diseases. When used in this way in dermatology hydrocortisone is superior to prednisolone (Frank and Stritzler 1955). The reason for this is not clear, but it may explain why there was no significant benefit in our patients treated with prednisolone inhalations. Difference in solubility of the two steroids will not readily explain the different results, because hydrocortisone acetate is said to be insoluble in water, whereas prednisolone is almost insoluble (*British Pharmaceutical Codex 1954* Supplement 1957, pp. 29 and 60). The lack of solubility of hydrocortisone acetate, however, may explain why the powder gave a beneficial effect by inhalation whereas none was demonstrated in our previous trial using a solution of hydrocortisone hemisuccinate. The solution may well have been rapidly absorbed without there being sufficiently long contact between the hydrocortisone and the bronchial mucosa for any beneficial effect to result.

TABLE III—ANALYSIS OF PATIENTS TREATED WITH HYDROCORTISONE

Result	No. and sex of patients	Age (yr.)	Duration of asthma (yr.)
Much improved	13 (4M., 9F.)	16–58 (av. 40.5)	0.5–45 (av. 17)
Improved	4 (1M., 3F.)	35–48 (av. 43)	3–19 (av. 7.5)
No better	7 (3M., 4F.)	21–63 (av. 46)	4–15 (av. 9.5)
Total	24 (8M., 16F.)	16–63 (av. 42)	0.5–45 (av. 13)

Summary and Conclusions

The value of hydrocortisone acetate and prednisolone powder inhalations in the treatment of chronic asthma has been assessed by a blind trial method.

Of 24 patients receiving the hydrocortisone acetate powder 17 were improved or much improved, a statistically significant figure compared with the results obtained in 13 patients with a blank inert powder.

There was no evidence in 7 patients that prednisolone was of any value when used in this way.

In our opinion this simple method of administering hydrocortisone acetate is well worthy of trial in the less severe cases of asthma.

We are grateful to Dr. Avery Cotton, of the Upjohn Company of America, for sending us the material, and to Dr. E. W. Emery, lecturer in medical physics, and Dr. S. W. Stanbury, lecturer in medicine, for their help.

TIME OF RECURRENCE OR CURE OF TUMOURS IN CHILDHOOD

W. EUGENE KNOX
M.D. Harvard
ASSISTANT PROFESSOR OF BIOLOGICAL CHEMISTRY, HARVARD MEDICAL SCHOOL, AT THE NEW ENGLAND DEACONESS HOSPITAL, BOSTON

ELIZABETH M. KINGSLEY PILLERS *
M.D. Cantab., D.C.H., D.M.R.T.
CLINICAL RESEARCH ASSOCIATE IN MEDICINE (TUMOUR THERAPY), THE CHILDREN'S MEDICAL CENTER, BOSTON

From the Cancer Research Institute, New England Deaconess Hospital, the Department of Biological Chemistry, Harvard Medical School, and the Children's Cancer Research Foundation, the Children's Medical Center, Boston, Massachusetts

Collins et al. (1956) have given theoretical reasons why the period is limited within which a treated neoplasm may recur (the "period of risk"). They showed that this held true in the results with 206 children from several series treated for Wilms' tumour (embryoma). There were no deaths or recurrences after the defined period of risk had ended. Patients surviving after the period of risk could be presumed to be cured according to a definite biological criterion. The existence of such a limit to the time within which treated tumours might recur would be clinically useful, and important in the study of the natural history of neoplasms. The present study was undertaken to see whether the experience with three types of childhood tumours (Wilms' tumour, neuroblastoma, and rhabdomyosarcoma) in a total of 244 children seen in a single institution confirmed the findings of Collins et al.

Method

Determination of the period when recurrence is possible is based on knowledge of the growth-rate of a tumour before treatment and extrapolation of this rate after treatment for a period long enough for even a single cell left behind to regrow to a tumour of diagnosable size. This time after treatment is the "period of risk." The choice of children as subjects for this study follows the ingenious use, by Collins et al, of the results with Wilms' tumour to test their hypothesis The growth-rate of tumours before treatment is not generally known for any group of patients, but in children this rate can be assumed within relatively narrow limits The tumour can have grown only since conception, or later, to reach its particular size at the time of treatment. The continued growth at the same rate of even a single cell for a period equal to that designated by the age of the child at treatment (plus nine months' gestation) would result in a tumour mass at least equal to that originally present at treatment. Therefore, if there is to be a recurrence it should appear before the end of the period of risk, at which time the child will be twice the age (plus nine months) that he was at the time of treatment For example, a child treated at one year of age will reach the end of the period of risk one year and nine months later, or at the age of two years and nine months, a child five years old, at ten years and nine months of age Tumours that develop later than conception, or that increase their growth-rate, would recur well before the end of the period of risk, as defined here Slowing of growth-rate, spontaneously or as a result of treatment, could result in recurrence after the end of the period of risk and would negate the prediction

---

* Present address: Department of Radiotherapeutics, University of Cambridge, England.

Two time-periods were ascertained for each patient (1) the time before treatment (age plus nine months' gestation), and (2) the time after treatment until the first recurrence of the tumour or the last negative follow-up Periods were determined to the nearest month In some patients in whom death followed shortly after the recognised recurrence and early in the period of risk, the time of death was accepted in lieu of fixing exactly the time of recurrence In patients surviving late into the period of risk, the time of recurrence was fixed more exactly by the date of the first objective signs found by radiographic, or, less commonly by clinical, examination A few patients with documented recurrences late in the period of risk survived well beyond the end of the period of risk, sometimes with supplementary or palliative treatment The delayed deaths of these patients did not vitiate the prediction of the time of their recurrences, since they had already shown evidence of recurrence of malignancy within the period of risk.

Patients

Records were found for a total of 244 patients treated at the tumour therapy clinic of the Children's Medical Center, Boston, during the past two decades, for the three types of tumours selected These particular tumours were selected simply because they are common The diagnoses in all patients in this study were confirmed by histological examination In each group the ages of patients ranged from newborn to about 16 years No selection was made as to the mode of therapy

Wilms' tumour—This was diagnosed in 92 patients The treatment was generally that of Gross and Neuhauser (1950) 5 patients were lost to follow-up immediately after hospital discharge while still apparently well, and these were not incorporated in the series Of the 87 remaining patients 27 were alive and without recurrence at the last follow-up and 60 had died or had had recurrences There was objective evidence from biopsy necropsy, or X-ray examination in 58 of the 60, for the presence of recurrent Wilms' tumour 2 other patients died at home of recurrences diagnosed solely on clinical grounds 15 of the patients without recurrences were beyond risk.

Neuroblastoma—126 patients with this diagnosis attended the tumour therapy clinic Nearly all of them received chemotherapy, usually after surgery and radiotherapy, as indicated At the time of the last follow-up, 18 patients were alive, with no evidence of recurrence, and 108 had already had recurrences 14 patients were beyond risk

TABLE I—SUMMARY OF RESULTS IN ALL PATIENTS STUDIED

	Recurrence		No recurrence		Total
	Dead	Alive	Period of risk	Safe period	
Wilms tumour	52	8	12	15	87
Neuroblastoma	102	6	4	14	126
Rhabdomyosarcoma	22	2	3	4	31
Total	176	16	19	33	244

Rhabdomyosarcoma—31 patients with this diagnosis were studied The therapy was the same as that described for the previous group At the time of the last follow-up, 7 were still alive (4 of them beyond risk), and 24 were dead or had recurrences

Results

The overall results are shown in table I Separate graphs have been made for the three different tumours (figs 1–3) The time before treatment (age plus nine months) was graphed against the time after treatment to recurrence or last follow-up for each of the patients A line drawn at 45° through the origin separates the period of risk from the safe period, and all recurrences can be seen to fall wholly within the period of risk. The patients followed long enough to be in the safe period without recurrence are presumambly cured Those with the period of risk, but negative at the last follow-up, are critical cases which should be followed closely until they are beyond risk

Discussion

The results in three of the commonest tumours of childhood confirmed the observations by Collins et al in a heterogeneous collection of 206 cases of Wilms' tumour There were no recurrences after the safe period was reached A single recurrence in the safe period would

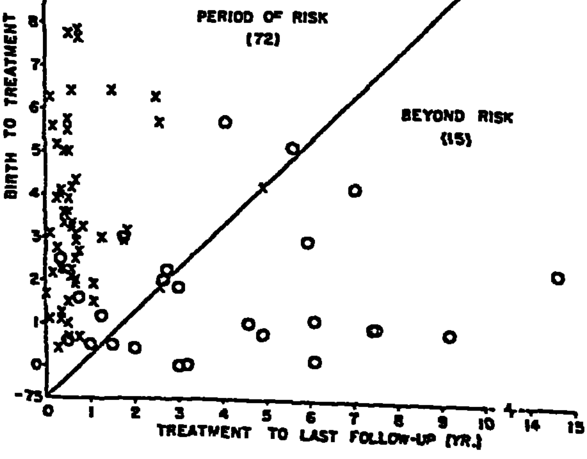

Fig 1—87 cases of Wilms tumour

disprove the thesis of an invariably constant or increasing rate of growth in tumours despite therapy. The results obtained are consistent with this thesis though they do not supply positive proof of it. The qualitative dichotomy of the post-treatment time into two periods—a period of risk and a safe period—is clear and arresting.

There is a highly significant difference in the results during these two periods by the x^2 test, but it is difficult to prove that this distribution did not arise by chance, because all tumours tend to recur early, long before the end of the period of risk. It is possible only to show, as did Collins et al. (1956), that the number of individuals cured by their criterion (i.e., reaching the safe period) was equal to that fraction of the whole group who were dying at a normal rate instead of an accelerated rate (i.e., equal to the "proportion cured," calculated from the statistics of the whole group by the method of Boag [1949]). The essential value of these results, however, is the application of a criterion of cure to an individual. The combined experience with a total of 293 Wilms' tumours, for example, strongly suggests that the criterion of cure discussed here is reliable.

The existence of a biological criterion of cure applicable to individuals treated for neoplasms will have important uses, even if applied *empirically without reference to its theoretical basis.* Even more important issues arise from the theoretical considerations. The criterion was developed from the reasonable assumption that neoplastic cells, like other populations, will tend to grow logarithmically at a constant rate under optimal conditions, so that their number (and therefore their mass) doubles in each interval of time. An interval of time after treatment, equal to that period when the tumour could have existed before treatment, therefore limits the period within which a recognisable tumour would recur. These results provide no direct evidence for the way tumours grow, and only circumstantial evidence for the theory itself. The results are consistent with this theory, since in no instance was a tumour *found to grow more slowly after treatment.* Such exceptions would be of particular interest in guiding tumour therapy.

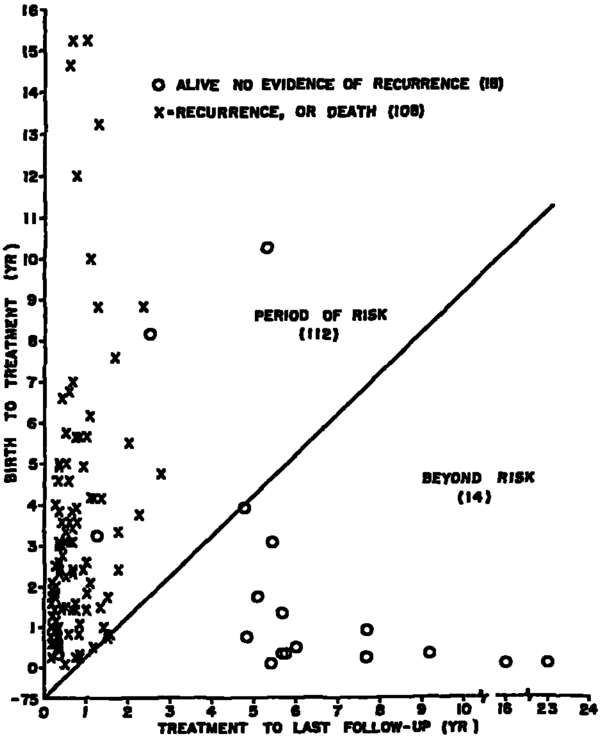

Fig 2.—126 cases of neuroblastoma.

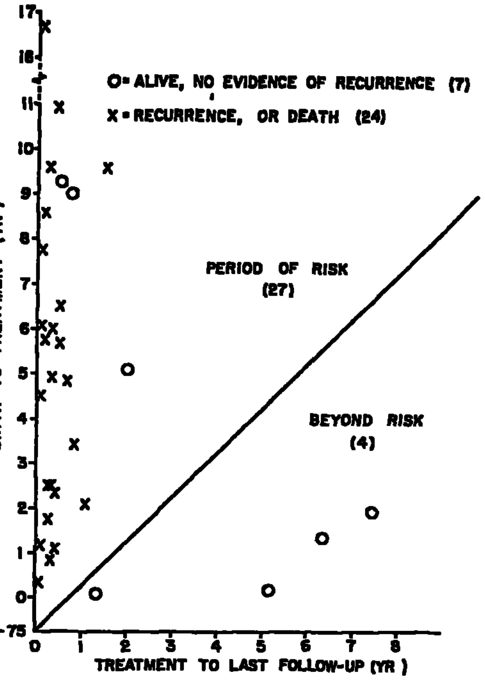

Fig 3.—31 cases of rhabdomyosarcoma.

Positive evidence for the theory may be obtained by the results of longer follow-ups of larger numbers of patients, or by direct determination of tumour growth-rates in individuals of different ages. In either of these ways an important implication of the theory could be tested—viz., that the tumour which grows to a recognisable mass in a young child is growing more rapidly than one attaining a similar mass in an older child. In a series sufficiently large to include late recurrences at each age, it should be possible to show that the disease in younger children usually recurred earlier than in older children. Also, by direct radiological measurement, metastases in young children should be found to grow more rapidly than those in older children. In adults the possible long time-span of tumour growth would prevent significant use of this theory, unless based on actual measurements of growth-rates of the individual tumours.

If the results of this study are accepted, one of the consequences should be the adoption of a sliding time-scale for the follow-up of patients after treatment. Definitive results can be known quickly in young children, but for older children the usual follow-up period should be extended, commensurate with their age at treatment.

Summary

The hypothesis that a treated neoplasm will recur only within a defined period of risk after treatment was tested and confirmed by the results in 244 children with tumours (Wilms' tumour, neuroblastoma, and rhabdomyosarcoma).

All tumour recurrences developed before the end of the period of risk, defined as twice the age at treatment plus nine months.

In 192 cases there was a recurrence. *Of the 52 cases in which there was no evidence of recurrence at the last follow-up, 19 were still within the period of risk. The remaining 33 were beyond risk and therefore could be assumed to be cured.*

TREATMENT OF UNDULANT FEVER

J Torres Gost

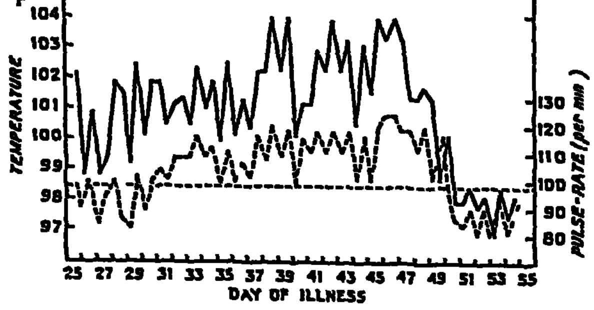
DIRECTOR, HOSPITAL DEL REY PARA ENFERMEDADES INFECCIOSAS, MADRID, SPAIN

Up to a few months ago we did not have a specific and efficacious antibiotic with which to treat undulant fever Neither streptomycin nor aureomycin, let alone vaccines, gold compounds, &c, was surely therapeutic in this infectious disease, and invariably the end-results, after treating the patients with these antibiotics, were complete failures, because almost constantly the disease recurred Even without complications—e g, spondylitis, which cripples for life—undulant fever used to last a year or two

Some months ago a new antibiotic, 'Cathomycin', was supplied to us for treating infections resistant to penicillin For various reasons and of my own initiative I used it to treat patients with undulant fever After treating the first few cases, I realised that cathomycin is a specific effective antibiotic in undulant fever Up to now we have treated 26 patients, who have been discharged from hospital completely cured, and not one has had a recurrence Of the 26 patients treated 20 had produced a positive blood-culture on admission and the remaining 6 had a positive agglutination test. Only the 20 patients with a positive blood-culture are discussed here Their details are shown in the accompanying table We treated the patients only when the undulant fever was at its height

The constant effect of cathomycin was remarkable (see figure) During the first five days' treatment no change is apparent, the pyrexia continues as before, and the symptoms remain just the same, but almost always on the fifth day the pyrexia resolves by crisis and all the symptoms (headache, insomnia, articular pain, anorexia, sweating, &c) disappear Splenomegaly also disappears, and by the end of the treatment the spleen has returned to its normal size and shape, no matter how large it was None of the patients relapsed

Dosage—A capsule containing 0 25 gs was given four-hourly until the day after the crisis (usually the sixth day) and then six-hourly for nine days to a total of 18 g Of course this dosage applies only to adults



Typical chart of temperature and pulse-rate in undulant fever before and during treatment with cathomycin.

ANALYSIS OF CASES OF UNDULANT FEVER AND TREATMENT

Case no	Sex	Age (yr)	Duration of disease before treatment	No of days' treatment before crisis	Temperature at beginning of treatment (°F)	Total dose of cathomycin (g)
1	F	35	2 mos	5	98·6—100·4	14·0
2	F	36	1 month	6	98 6— 99 5	12·0
3	M	7	1 month	5	100 4—102 2	13 5
4	M	33	3 mos	5	99 5—102 2	27·0
5	M	52	1½ mos.	5	99 0—102 2	17 5
6	M	31	2 weeks	10	100·4—104 0	20 0
7	M	11	2 weeks	6	101 5—103 6	13 5
8	F	26	10 days	6	100 4—101 3	13 75
9	M	30	3 weeks	5	99 5—100 4	17 5
10	M	27	1 month	5	100 4—102 2	20 5
11	M	30	1 month	6	101 3—103 1	16 0
12	M	17	2 weeks	4	100·4—102 2	18 7
13	M	45	2 mos	5	100 4—103 1	20 0
14	M	52	2 weeks	5	99 5—102 2	20·0
15	M	45	2 mos	5	99 1—103 1	18·0
16	M	57	1 yr	4	98 6—100 4	18 0
17	M	19	3 mos	5	99 5—100 4	18·0
18	F	7	1 month	5	100·4—101 3	12 5
19	F	32	1 month	5	100 4—101·4	18 0
20	M	18	2 mos	5	100 0—101 3	18 0

Laboratory Findings—On the third day of treatment liver-function tests (Kunkel's, Maclagan's, Hanger's, and Wuhrmann's), which were frequently made, were always negative The leucopenia, which sometimes was very severe, rapidly disappeared Anæmia, which also is common in undulant fever, gradually returned to normal The platelet count was usually normal and did not vary in any way during the treatment No organic alterations were found

Psychology—The patient's state of mind was much improved as soon as his temperature had returned to normal Many of the chronic patients who had become pessimistic became cheerful and self-confident again after losing their fever and pain

Side-effects—A quarter of the patients manifested intolerance of cathomycin

Case 10 (see table) during the first three days of treatment had hyperchlorhydria, which was relieved by alkalis without stopping the treatment.

Case 5 had a generalised urticarial rash, with pyrexia up to 104°F, but with the patient's cooperation we did not withhold cathomycin but gave him the full fifteen days' treatment. On the day that he stopped having cathomycin his temperature returned to normal, two days later the exanthema disappeared, and he was discharged completely cured

Case 6 was treated for ten days On the eighth day an urticarial eruption appeared, causing him so much discomfort that we had to withhold cathomycin for two days, during which time the rash disappeared We gave him cathomycin again, but after the third capsule the exanthema reappeared, accompanied by pyrexia up to 103°F Since the patient asked us not to stop the treatment, we carried on for the remaining four days Two days later all his ailments disappeared, and on the third day he was discharged home completely cured

In case 8 urticaria appeared on the eighth day of treatment, but the treatment was continued to the tenth day, when we had to withhold cathomycin because the patient could no longer bear the itching caused by the rash. Four days later, when the urticarial rash had subsided, we continued the treatment, but at the third capsule the exanthema reappeared, this time with such severe symptoms that we had to abandon treatment with cathomycin Although the patient had had only 10 days' treatment he was definitely cured, and three days later he was discharged

So far the urticarial eruption has been the only inconvenience caused by cathomycin

Conclusion

In all our knowledge and experience of undulant fever we have never seen or achieved such good results This infectious disease is completely cured in about five days without a single recurrence For these reasons we regard cathomycin as an efficacious and specific antibiotic to be introduced and used in the treatment of undulant fever If our findings are confirmed, as we feel sure they must be, we may consider the battle against brucellosis to have been won

HÆMOGLOBIN-H TRAIT IN A NEPALESE GURKHA WOMAN

M C Brain

LECTURER IN BIOCHEMISTRY, UNIVERSITY OF MALAYA, SINGAPORE

Since Pauling et al (1949) described the electrophoretic properties of sickle-cell hæmoglobin, several other types of abnormal adult human hæmoglobin have been detected Of these, hæmoglobins S, C, D, E, and G have a mobility lower than that of normal adult hæmoglobin, while hæmoglobins I, J, K, and H, that of Cabannes et al (1955), and the Liberian 2 of Robinson et al (1956) have a mobility higher than that of normal adult hæmoglobin Hæmoglobin H differs from all the other abnormal hæmoglobins in having an anodal mobility at pH 6 5, the other *hæmoglobins having a cathodal mobility at this* reaction

Hæmoglobin H was described simultaneously in two Chinese siblings settled in America by Rigas et al (1955) (1956) and in seven Greeks by Gouttas et al (1955) These patients had hypochromic microcytic anæmia resistant to therapy, with splenomegaly, and with a blood-picture very like that of thalassæmia but accompanied by the presence of hæmoglobin H in the erythrocytes Hæmoglobin-H trait has also been found in Thais (Minnich etal 1956), in Indochinese in Indonesia (Lie-Injo Luan Eng et al 1957), in Filipinos (Motulsky 1956), in Singapore Chinese (Vella 1957), in a Greek Cypriot (Ager and Lehmann 1957), in a Malay (Lehmann and Singh 1957), and in a Trans-Jordanian Arab (White et al 1956)

The Nepalese Gurkha woman described here presented *with a severe hypochromic anæmia and splenomegaly* As the anæmia responded to treatment, she was held to have a nutritional iron deficiency such as is commonly found in her race Additional support was given to this belief when the anæmia relapsed on her becoming pregnant and when she was found to have ankylostomiasis The anæmia now responded only partially, despite large doses of parenteral iron When this ultimate lack of response to treatment was recognised, a thalassæmia-like anæmia was considered, and electrophoresis was carried out This revealed the presence of hæmoglobin H

Electrophoresis was done on *Whatman filter paper (3 MM)* between glass plates measuring 14 in × 10 in × 0 25 in, treated with silicone stopcock grease, and clamped with four Waverley clips (no 3), using veronal buffer pH 8 8 (ionic strength 0 06) and citrate buffer pH 6 5 (ionic strength 0 05) Runs were made in a refrigerator, at about 5°C, at 360V for five or six hours (Chernoff 1955) *Alkali-*resistant hæmoglobin was measured by the Chernoff technique (Chernoff 1955) Inclusion bodies were demonstrated by supravital staining with brilliant cresyl blue (Gouttas et al 1955)

Case-report

A Nepalese woman, aged 24, complained of fever soon after arriving in Malaya from India in April, 1956 She was admitted to the British Military Hospital, Singapore, with a temperature of 99°F, pale mucosæ, and slight icterus Her liver was palpable to one fingerbreadth below the costal margin and a firm non-tender spleen was palpable to two fingerbreadths Laboratory investigations showed red cells 3,050,000 per c mm, Hb 6 8 g per 100 ml, white cells 5100 per c mm (polymorphs 57%, lymphocytes 35%, monocytes 5%, eosinophils 3%) *Malarial parasites were absent, a blood-film showed* poorly filled red cells with considerable anisocytosis and poikilocytosis Serum-bilirubin 0 4 mg per 100 ml, no urobilinogen in urine Lung fields clear on radiography

Fig 1—Peripheral blood smear

Treatment and Progress

She was treated with oral iron, and in three weeks her hæmoglobin increased to 8 9 g per 100 ml, and red cells to 3,090,000 per c mm A blood-film showed active regeneration She was discharged from hospital with a diagnosis of iron-deficiency anæmia

She was readmitted in November, 1956, with symptoms of anæmia and was now twenty-two weeks pregnant Apart from the pregnant uterus, the clinical findings were essentially the same as at her previous admission Hb 5 2 g per 100 ml, blood-film showed hypochromic microcytic red cells but no target cells, white-cell count normal Stools contained ova of *Ancylostoma duodenale*

She was treated with tetrachlorethylene and with 'Imferon' The anæmia persisted, but the hæmoglobin gradually rose to 9 6 g per 100 ml before she gave birth on March 4, 1957, to a premature female baby weighing 3 lb 13 oz

She was first seen by one of us (M C B) a month after delivery On examination she had the typical mongoloid features and short stature of her race The mucosæ were pale and fingernails and tongue normal The liver and spleen were palpable to the same extent as before She had no abnormal physical signs in the nervous, respiratory, and cardiovascular systems, apart from an apical systolic murmur

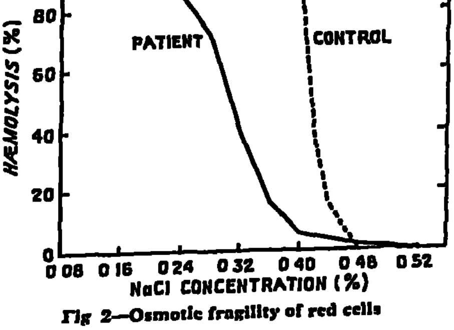

Fig 2—Osmotic fragility of red cells

---

* Present address British Military Hospital, Kluang, Malaya

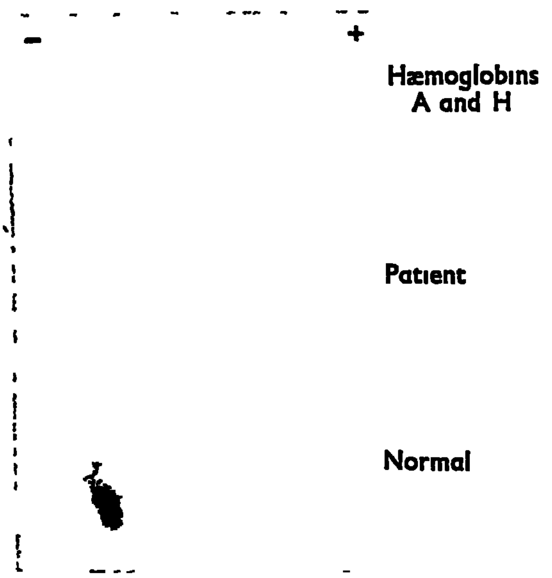

Fig. 3—Electrophoresis pattern (pH 6·5) of hæmoglobin solutions A and H standards, patient, and normal.

Investigations

Red cells 5,600,000 per c.mm., Hb 11·5 g. per 100 ml., packed cell volume 37%, mean corpuscular volume 66 c μ, mean corpuscular hæmoglobin 21 μμ, mean corpuscular hæmoglobin concentration 31%, a stained smear showed considerable anisocytosis and poikilocytosis (fig. 1). No target cells were seen. Sickling could not be induced. Reticulocytes 5%. White-cell count normal. The osmotic fragility curve (fig. 2) showed increased resistance to hypotonic saline solution, there was 5% hæmolysis in 0·4% sodium chloride and 60% in 0·3% sodium chloride. Bone-marrow was very cellular and showed normoblastic erythroid hyperplasia, the myeloid/erythroid ratio being 1/1.

Electrophoresis gave the results shown in fig. 3. Hæmoglobin A 70%, hæmoglobin H 30%, alkali-resistant hæmoglobin 0%.

Supravital staining of peripheral blood with brilliant cresyl blue revealed inclusion bodies in 40% of the red cells (fig. 4). In bone-marrow stained by the same technique 1% of the red cells contained intracellular inclusions. The inclusion bodies were not seen in any nucleated red-cell precursors.

Serum-bilirubin 1·0 mg. per 100 ml., liver-function tests normal. Serum-albumin 4·4 g. per 100 ml., serum-globulin 1·85 g. per 100 ml. Urine no urobilinogen detected. Blood-group O, rhesus-positive. Blood Wasserman reaction negative. Coombs antiglobulin test negative. A test-meal showed acid secretion, which was confirmed by a positive 'Diagnex' test.

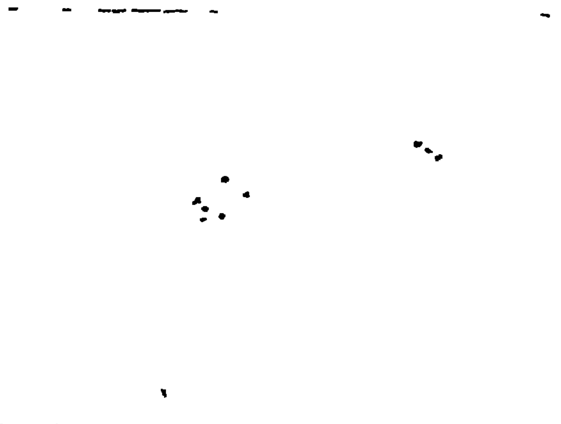

Fig. 4—Peripheral blood stained supravitally with brilliant cresyl blue to show intraerythrocytic inclusion bodies.

Uropepsinogen excretion 57 units an hour. Serum-iron 205 μg per 100 ml. Stool no ova of *Ancylostoma duodenale* found in six specimens, no occult blood.

Radiographs of the skull showed an area in which the diploic space was enlarged, but no spiculation was evident. Radiographs of the hands were normal.

Family History

The patient is the youngest of a family of five. Her parents, brother, and three sisters are alive and well but not available for study. Her husband is quite fit and not anæmic, on electrophoresis his hæmoglobin was normal, alkali-resistant hæmoglobin 0%. Her daughter at the age of 6 months was normal for her age.

3,870,000 per c.mm., Hb 9·9 g. per 100 ml. Blood-film slightly hypochromic but otherwise normal. No intraerythrocytic inclusions bodies. Reticulocytes 1·6%, white-cell count normal. Electrophoresis at 5 weeks hæmoglobins A+F, alkali-resistant hæmoglobin 60%, at 10 weeks hæmoglobins A+F, alkali-resistant hæmoglobin 40%, at 16 weeks hæmoglobins A+F, alkali-resistant hæmoglobin 17%, at 6 months hæmoglobin A, alkali-resistant hæmoglobin 3%.

Discussion

Hæmoglobin H is the only known abnormal hæmoglobin which in the heterozygous state produces a clinical syndrome of mild anæmia resistant to therapy and associated with splenomegaly and little if any hæmolysis. The diagnosis is possible only on electrophoresis at both an alkaline and a slightly acid reaction, though supravital staining with brilliant cresyl blue will show up intraerythrocytic inclusion bodies of denatured hæmoglobin H on to which the cresyl blue has been adsorbed. It is not yet certain whether these intraerythrocytic inclusion bodies are associated only with hæmoglobin H.

Minnich et al. (1956) have reported inclusion bodies in a case of hæmoglobin-E thalassæmia in Thailand. One of us (F. V.) has shown that both hæmoglobins E and H can be precipitated from solution by adding brilliant cresyl blue or metabisulphite, whereas hæmoglobins A and F are more resistant to precipitation (Vella 1957). Our inability to demonstrate inclusion bodies in the red-cell precursors in the bone-marrow, and the small number of red cells containing inclusion bodies seen there, suggest that a physicochemical change in the hæmoglobin with ageing of the red cell may lead to its precipitation with brilliant cresyl blue. This might explain the marked variability in the quantity and density of inclusion bodies seen in red cells in the peripheral blood.

The peripheral blood-picture in persons with hæmoglobin-H trait has been described as indistinguishable from that in Cooley's anæmia. In fact, these cases are usually classed as thalassæmia syndrome until electrophoresis is done. Motulsky (1956) has concluded:

> "In the present state of our knowledge, the demonstration of hæmoglobin H apparently signifies the simultaneous presence of Thalassæmia. Thalassæmia-Hæmoglobin H Disease therefore may be considered a variant of Thalassæmia in which the Thalassæmia gene in a yet unknown manner activates the expression of hæmoglobin H."

Apparently the expression of the hæmoglobin-H gene may also be enhanced by the simultaneous presence of a gene for another abnormal hæmoglobin (Vella and Wells 1957).

Production of hæmoglobin H is controlled by a recessive gene, so far only three cases are known in which people with hæmoglobin H have produced offspring. Rigas et al. (1956) found the child of one of their patients to exhibit an iron-resistant anæmia with target cells and microcytosis but no splenomegaly and no demonstrably abnormal hæmoglobin, and they diagnosed thalassæmia minor. However, one of the patients of Gouttas et al.

(1955) is married to a clinically and hæmatologically normal partner and has produced a child known to carry hæmoglobin H Our own patient's daughter showed no abnormality of hæmoglobin at the age of 6 months No abnormal hæmoglobins have yet been detected before the 12th week of life (Lie-Injo Luan Eng 1956)

As no siblings or parents of this patient were available for study, the relation of the hæmoglobin-H recessive gene to the gene(s) responsible for the thalassæmia could not be ascertained in this case

The initial response of this patient's anæmia to therapy and her relapse on becoming pregnant are attributed to a concomitant deficiency of iron The failure of the hæmoglobin to rise to a normal level once the ankylostomiasis had been treated and the iron deficiency had been made good, is characteristic of the thalassæmia-like anæmias and agrees with the descriptions published of hæmoglobin-H trait Once the nature of the anæmia was appreciated, further attempts at "treatment" were discontinued The patient remains well and symptom-free, leading an active life with a hæmoglobin of between 8 0 and 11 0 g per 100 ml

Summary

A case is described of a Nepalese Gurkha woman, aged 24, with hypochromic anæmia, splenomegaly, and ankylostomiasis, partially responding to treatment

On electrophoresis hæmoglobin H was found to constitute 30% of the total hæmoglobin

The patient's daughter, aged 6 months, has no abnormal hæmoglobin and is clinically normal

We are grateful to the Director-General of Army Medical Services for permission to publish, and to Lieut -Colonel T E Field, R A M C, and the staff of the Pathology Laboratory, FARELF, for the hæmatological and biochemical investigations

"The problem of air pollution arises from the fact that the cost of curing it is not directly borne by those who would benefit from its cure This applies whether the pollution comes from an individual householder's smoky chimney or from a large industrial boiler or furnace Hence, although the financial saving to the nation as a whole from the substantial elimination of air pollution would almost certainly pay the whole of the cost of this elimination, there is no way of making such a payment to those who would have to bear the costs This means that we either have to find considerably cheaper means of eliminating air pollution than those at present known or some method of subsidising gas cleaning"—Prof M W THRING, F INST P, in a preface to *Air Pollution*, a book based on papers given at a conference held at the University of Sheffield, September, 1956 London, 1957

ANAPHYLAXIS AFTER ORAL SULPHADIAZINE

TWO REACTIONS IN THE SAME PATIENT WITHIN EIGHT DAYS

P M BINNS

M B Leeds, D Obst

LATELY HOUSE-SURGEON, OTLEY GENERAL HOSPITAL, YORKS

AN anaphylactic reaction usually follows parenteral administration of a foreign substance, though it can follow ingestion or inhalation The reactions described here followed the giving of sulphadiazine by mouth

Case-report

A lady schoolteacher, aged 41, had had sore throats for about a year, and four months before admission her doctor had given her a course of sulphadiazine

Eight days before admission she had a sore throat, and her doctor prescribed sulphadiazine as 4 tabs (2 g) stat, and 2 tabs (1 g) four-hourly She took 4 tablets, and within half an hour she was "lathered" in sweat, but felt "cold and shivery" She had a tickling cough, but no breathlessness or wheezing, and noted itching white urticarial weals "like large heat lumps up to an inch in diameter" appearing on arms, spreading to face (which "felt tight and prickly"), and then to rest of the body The urticaria was followed by generalised erythema within an hour Her mouth was swollen and her tongue stiff, and her skin felt to be burning furiously She vomited once, but had no diarrhœa or loss of consciousness She decided not to take the tablets as prescribed during the rest of that day

Next morning the redness had disappeared, but as her throat was still sore she took 2 tablets of sulphadiazine and continued to do so four-hourly for three days without ill effect Her throat was then much improved and she felt better and ceased to take the tablets Thirty-six hours before admission the "bad throat" recurred

At 11 30 A M on the day of admission she took 2 tablets of sulphadiazine Within half an hour she started sweating profusely and felt cold Itching urticarial areas 1½ in in diameter appeared on her arms and spread all over her body, followed by redness within half an hour At this stage she had an irritating cough with slight wheezing and breathlessness Then she had violent cramp-like pains in the epigastrium, passing into the lower abdomen in less than ten minutes She twice vomited greenish-yellow fluid with coincidental severe exhausting diarrhœa, when she felt very weak and ill, and "did not care whether she lived or died" He sister said her colour was greyish purple, with blue lips, and she was groaning and shivering as she tried to sit on the commode Her eyes were staring and then deviated upwards, followed by loss of consciousness for a few minutes with convulsive movements of arms and legs Gradually consciousness returned Her doctor arrived shortly after this and noted that she was profoundly shocked and pulseless She vomited once in the ambulance

She had no history of allergic disease, but had had deep X-ray treatment for thyrotoxicosis in 1940 A sister had asthma

Condition on Admission

Her eyes were staring and her conjunctivæ suffused and bloodshot Face ashen grey with cyanosis of lips She appeared too weak to talk, but was trembling enough to cause the bed to shake Her hands and feet were cold and blue On her trunk, limbs, back of neck, and scalp were urticaria (with interlacing pseudopodia) and bright erythematous areas Temperature 97 6°F The pulse was not palpable, and the blood-pressure (B P) irrecordable The heart-rate (at auscultation) was 138 a minute and the respiratory rate 38 There was no bronchospasm The tonsils were large and injected No other gross abnormalities were found

Course

10 minims of adrenaline 1/1000 solution was given subcutaneously at 2 P M Within ten minutes, the trembling had

ceased, but retching and diarrhœa continued intermittently. She gradually improved during the afternoon, another 3 minims of adrenaline was given at 5 P.M. Next morning her pulse-rate was 90 a minute and B.P. 120/80 mm. Hg, there were still occasional urticarial weals on her body. A throat swab revealed *Staphylococcus aureus*.

Discussion

Of special interest are the rapidity of onset of symptoms after administration by mouths and two episodes separated by freedom from reactions while taking the drug.

Dale (1920) postulated a latent period of twelve to fourteen days after the initial exposure to the foreign substance, during this time antibody is formed and becomes fixed in the cells. When the foreign substance again reaches the circulation, any plasma-antibody is precipitated, the excess foreign agent reacts with antibody within the cells to liberate histamine and other substances, which produce anaphylactic manifestations.

Landsteiner (1936) observed that simple chemical substances could combine with proteins in the body to form a modified protein antigen. A molecule containing a benzene-ring nucleus with an $-NH_2$ group attached, or a molecule with a pyrimidine nucleus, is highly antigenic. Sulphadiazine contains both a benzene ring with an $-NH_2$ group, and a pyrimidine group.

The time intervals in this case accord with Dale's hypothesis: a sensitising dose four months before admission, a reaction eight days before, then freedom from symptoms for three days while on the drug, when the antibody in cells had been neutralised, and then a reaction on the day of admission, when the antibody here had again built up in the tissue cells.

My thanks are due to Prof. P. J. Moir for kind permission to publish this report.

PERIURETERIC fibrosis (*Lancet* 1957) is probably not so uncommon as the paucity of published reports thereof suggests. We describe here a further case, in which, as is characteristic of this condition, we followed many false trails before we stumbled on the correct diagnosis.

Case-report

A man, aged 39, was admitted to the medical wards of the Royal Sussex County Hospital on Feb. 25, 1957, because of repeated attacks of vomiting accompanied by a girdle-type pain starting in both loins and radiating to the epigastrium, where it persisted in attacks lasting five hours. For some months he had had vague abdominal aching centred in the region of his umbilicus, and he had lost about 2 st. in weight and felt ill. The pain was unrelated to food, and there had been no disturbance of micturition.

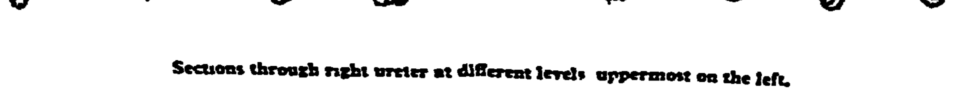
On admission he was thin, ill-looking, and apprehensive but did not present any abnormal physical signs. In view of his nausea, vomiting, and epigastric pain attention was at first focused on his alimentary tract. A barium meal showed no abnormality other than partial loss of mobility of the terminal ileum, this last was thought to be due to adhesions. Examination of the blood showed microcytic anæmia (Hb 11 g. per 100 ml.), white cells 7900 per c.mm., but a surprisingly high blood-urea level (138 mg. per 100 ml.) and serum-potassium level (26.3 mg. per 100 ml.), all the other serum-electrolyte levels being normal. The urine was sterile, with a few red cells and white cells present in the centrifugal deposit. Intravenous pyelography showed a non-functioning right kidney and some early dilatation of the calyces in the left kidney. The fact that the left ureter persistently lay near the midline did not at first attract attention.

Cystoscopy on March 18, 1957, showed a normal bladder, but a catheter could not be passed more than 5 cm. up the right ureter. A further attempt three days later also failed. During this first month the patient's general condition improved spontaneously, as did his blood chemistry, the blood-urea level reaching 264 mg. per 100 ml. before falling to normal levels by the end of March. This spontaneous recovery of renal function, which we now know to be characteristic of periureteric fibrosis, was not appreciated at the time.

Exploration of the right kidney was done on March 28 through an anterolateral approach with a view to either a plastic operation for hydronephrosis or a nephrectomy. Great difficulty was experienced in finding the ureter. For a time what proved to be the dilated upper end of the ureter was taken to be the renal vein as it ran transversely before disappearing into a large firm pinkish mass, which involved all the retroperitoneal structures from the level of the body of L2 vertebra to that of L5 vertebra. The ureter, identified distally, resembled a vas deferens in its calibre and consistence, and was freed down to the pelvic brim. No peristalsis was seen. The mass was thought to be neoplastic, and the changes in the ureter to be due to neoplastic infiltration. Nephro-ureterectomy was then done. Recovery was uneventful.

Pathology.—The kidney measured 11 × 6.5 × 4 cm. and weighed 186 g., with 14 cm. of ureter attached. There was mild hydronephrosis, with dilatation of the upper part of the ureter, but the lower 6 cm. of ureter was contracted and hard, with somewhat the texture of a vas deferens. In the narrowed segment of ureter the lumen was narrowed to a slit but retained normal epithelium. In the wall, lying outside the muscularis but partly infiltrating it was a plaque of young fibrous tissue with patchy lymphoid infiltration, chiefly perivascular. One small arteriole showed what appeared to be subacute arteritis with cellular infiltration of the media and proliferation of the endothelium. The kidney had a distinct zone of lymphoid infiltration at the outer edge of the cortex, with focal lymphoid infiltration, again chiefly perivascular, scattered elsewhere. There were less arteriolar hyalinisation and more round-cell infiltration than are usual in pyelonephritis. This condition affected the renal parenchyma as well as the ureter, and could only be called "inflammatory" by using this word in a very wide sense. Histologically it was more like temporal arteritis or a collagen disease. The appearances resembled those described by Raper (1955) for periureteric fibrosis, except that there was no calcification (see figure).

Prognosis.—It was now appreciated that the prognosis was good, provided that complete ureteric obstruction did not develop on the left side by involvement in this inflammatory mass. The left ureter was already displaced medially,



Sections through right ureter at different levels, uppermost on the left.

(1955) is married to a clinically and hæmatologically normal partner and has produced a child known to carry hæmoglobin H Our own patient's daughter showed no abnormality of hæmoglobin at the age of 6 months No abnormal hæmoglobins have yet been detected before the 12th week of life (Lie-Injo Luan Eng 1956)

As no siblings or parents of this patient were available for study, the relation of the hæmoglobin-H recessive gene to the gene(s) responsible for the thalassæmia could not be ascertained in this case

The initial response of this patient's anæmia to therapy and her relapse on becoming pregnant are attributed to a concomitant deficiency of iron The failure of the hæmoglobin to rise to a normal level once the ankylostomiasis had been treated and the iron deficiency had been made good, is characteristic of the thalassæmia-like anæmias and agrees with the descriptions published of hæmoglobin-H trait Once the nature of the anæmia was appreciated, further attempts at "treatment" were discontinued The patient remains well and symptom-free, leading an active life with a hæmoglobin of between 8 0 and 11 0 g per 100 ml

Summary

A case is described of a Nepalese Gurkha woman, aged 24, with hypochromic anæmia, splenomegaly, and ankylostomiasis, partially responding to treatment

On electrophoresis hæmoglobin H was found to constitute 30% of the total hæmoglobin

The patient's daughter, aged 6 months, has no abnormal hæmoglobin and is clinically normal

We are grateful to the Director-General of Army Medical Services for permission to publish, and to Lieut -Colonel T E Field, R A M C, and the staff of the Pathology Laboratory, FARELF, for the hæmatological and biochemical investigations

"The problem of air pollution arises from the fact that the cost of curing it is not directly borne by those who would benefit from its cure This applies whether the pollution comes from an individual householder's smoky chimney or from a large industrial boiler or furnace Hence, although the financial saving to the nation as a whole from the substantial elimination of air pollution would almost certainly pay the whole of the cost of this elimination, there is no way of making such a payment to those who would have to bear the costs This means that we either have to find considerably cheaper means of eliminating air pollution than those at present known or some method of subsidising gas cleaning"—Prof M W THRING, F INST P, in a preface to *Air Pollution*, a book based on papers given at a conference held at the University of Sheffield, September, 1956 London, 1957

ANAPHYLAXIS AFTER ORAL SULPHADIAZINE

TWO REACTIONS IN THE SAME PATIENT WITHIN EIGHT DAYS

P M BINNS
M B Leeds, D Obst
LATELY HOUSE-SURGEON, OTLEY GENERAL HOSPITAL, YORKS

AN anaphylactic reaction usually follows parenteral administration of a foreign substance, though it can follow ingestion or inhalation The reactions described here followed the giving of sulphadiazine by mouth

Case-report

A lady schoolteacher, aged 41, had had sore throats for about a year, and four months before admission her doctor had given her a course of sulphadiazine

Eight days before admission she had a sore throat, and her doctor prescribed sulphadiazine as 4 tabs (2 g) stat, and 2 tabs (1 g) four-hourly She took 4 tablets, and within half an hour she was "lathered" in sweat, but felt "cold and shivery" She had a tickling cough, but no breathlessness or wheezing, and noted itching white urticarial weals "like large heat lumps up to an inch in diameter" appearing on arms, spreading to face (which "felt tight and prickly"), and then to rest of the body The urticaria was followed by generalised erythema within an hour Her mouth was swollen and her tongue stiff, and her skin felt to be burning furiously She vomited once, but had no diarrhœa or loss of consciousness She decided not to take the tablets as prescribed during the rest of that day

Next morning the redness had disappeared, but as her throat was still sore she took 2 tablets of sulphadiazine and continued to do so four-hourly for three days without ill effect Her throat was then much improved and she felt better and ceased to take the tablets Thirty-six hours before admission the "bad throat" recurred

At 11 30 A M on the day of admission she took 2 tablets of sulphadiazine Within half an hour she started sweating profusely and felt cold Itching urticarial areas 1½ in in diameter appeared on her arms and spread all over her body, followed by redness within half an hour At this stage she had an irritating cough with slight wheezing and breathlessness Then she had violent cramp-like pains in the epigastrium, passing into the lower abdomen in less than ten minutes She twice vomited greenish-yellow fluid with coincidental severe exhausting diarrhœa, when she felt very weak and ill, and "did not care whether she lived or died" He sister said her colour was greyish purple, with blue lips, and she was groaning and shivering as she tried to sit on the commode Her eyes were staring and then deviated upwards, followed by loss of consciousness for a few minutes with convulsive movements of arms and legs Gradually consciousness returned Her doctor arrived shortly after this and noted that she was profoundly shocked and pulseless She vomited once in the ambulance

She had no history of allergic disease, but had had deep X-ray treatment for thyrotoxicosis in 1940 A sister had asthma

Condition on Admission

Her eyes were staring and her conjunctivæ suffused and bloodshot Face ashen grey with cyanosis of lips She appeared too weak to talk, but was trembling enough to cause the bed to shake Her hands and feet were cold and blue On her trunk, limbs, back of neck, and scalp were urticaria (with interlacing pseudopodia) and bright erythematous areas Temperature 97 6°F The pulse was not palpable, and the blood-pressure (B P) irrecordable The heart-rate (at auscultation) was 138 a minute and the respiratory rate 38 There was no bronchospasm The tonsils were large and injected No other gross abnormalities were found

Course

10 minims of adrenaline 1/1000 solution was given subcutaneously at 2 P M Within ten minutes, the trembling had

Reviews of Books

Medical History of the Second World War

Army Medical Services Campaigns Vol ii F A E CREW, F R S H M Stationery Office 1957 Pp 537 84s

THE second volume in this series has the same plan and the eminent virtues of the first [1] Its subjects are the defeats at Hong Kong and in Malaya and the second (and victorious) phase of the battles in North Africa There is also an account of the health of our subarctic garrisons and—probably of the most general interest—a detailed study of the medical aspects of captivity in Japanese hands

In those years we went where we were sent, did as best we could, and—quite often—were sure that we could have done better for our patients and for ourselves if we had had the ordering of affairs in our own hands Fifteen years later it is more profitable to forget pompous authority, supplies ill-chosen, late in arrival, or non-existent, the weeks of empty idleness, and the days and nights of endless and sometimes useless toil If read between the lines this book makes no effort to conceal failure or incompetence, but, without bombast, it shows that there was far more to praise than to blame in the direction of the Army Medical Services For everyone from the Director-General to the battalion medical officer every new campaign is to some extent a leap in the dark Plans must be made, men must be trained, and stores assembled at home the Army Medical Department has no infallible soothsayer to supplement inadequate intelligence or anticipation The personnel are not what A M D 1 would choose but what they have in hand The good soldier is he who can make the best use of all these wherever he finds himself, and, in retrospect, the job was done well far more often than badly The heroes of this book are the A D M S, D D M S, and D M S who faced and solved so many problems new to them and barely mentioned, we would guess, in the scholarly peace of Millbank They planned, devised, begged, cajoled, and improvised with two ends in view—to maintain the health of the fighting Army and to succour the wounded as best they could

There are two lessons to be learned—or relearned First, no administrator who is not a doctor can have the flexible pragmatic outlook needed to employ slender resources to the most profitable end, and there can be no better evidence than this book that the professional direction of the Army Medical Services must be maintained The second lesson is not for the professional soldier only and may be the more urgent By 1939 the lessons of 1918 had been forgotten, if there is another war those of 1945 may have to be learned again at dreadful cost Those responsible for the planning of civil defence will be neglecting their duties if they do not read these volumes thoughtfully and often

Artificial Limbs

LEON GILLIS, M B E, M B, F R C S, consultant orthopædic surgeon to Queen Mary's Hospital, Roehampton, East Ham Memorial Hospital, and St John s Hospital, Battersea London Pitman Medical Publishing Co 1957 Pp 449 £15

Ultima ratio regum ran the inscription about the mouths of Louis XV's cannon—"the last argument of kings" "The last argument of orthopædic surgeons" might once have been engraved on the blade of an amputation knife, but today it would not ring true, for the view is now well established that amputation marks not the end but the beginning of a phase of treatment Since 1948 almost every patient in this country who has undergone amputation—there are a few residential stipulations—has been entitled not only to an artificial limb (and a spare duplicate) but also to the help of a fitting service prepared to advise and train him in its use

Mr Gillis points out that we can justifiably take pride in the fact that Great Britain has led the way in establishing such an organisation But little has been published about its activities, materials, and techniques, and his new book, based on his experience at Roehampton, fills this gap

The work, which is complementary to Mr Gillis's earlier monograph on amputation, is in three sections one concerned with measuring the patient for an artificial limb and the fitting of it, another with the construction of the prostheses, and a third with methods of reablement No better survey of British limb-fitting practice, and of tried and tested procedures, could be wished for The surgeon who studies it will find that he can do much to bridge the gap that still sometimes exists between the surgical ward and the limb-fitting centre

Livingstone, the Doctor

MICHAEL GELFAND, O B E, M D, F R C P Oxford Basil Blackwell 1957 Pp 333 42s

A GOOD account of David Livingstone's journeys is always attractive reading, and in some respects Dr Gelfand's is even more interesting to the medical reader than earlier ones have been Its maps are particularly good, and emphasis is laid on the medical side of Livingstone's work, which was considerable and fascinating His medical observations are some of the earliest records on the diseases of Africa He was an accurate observer, who had to rely on the simplest aids to diagnosis He regretted that he had not been able to do necropsies "No inspection of the body is allowed by their people, and the place of sepulchre is carefully concealed I had to rest satisfied with conjecture"

Livingstone observed for the first time the association between relapsing fever and the bite of a tick, one of the earliest records of a disease transmitted by an insect He gave an excellent account of tropical ulcer, a common and very disabling condition at that time, and he probably was one of the first to describe in Africa the boils produced by the maggot fly Two years later he recorded the presence of an insect (one of the filarial worms) in the aqueous humour of the eye of one of his men And, above all, he made notable contributions to the study of malaria

Hewer's Textbook of Histology (7th ed London William Heinemann 1957 Pp 438 27s 6d)—Dr C L Foster has extensively revised the sections describing the cell, the connective tissues, the liver and the pituitary, but the other chapters are virtually the same as in the sixth edition Some new illustrations have been included to supplement the many existing photomicrographs and line drawings The inclusion of additional figures, without altering the numbering, has necessitated the rather cumbersome use of letters in addition to numbers to designate the new illustrations Readers may be disappointed to find no mention of sex-chromatin, nucleic acids, or "spreading factors", and no more than a passing reference to amorphous intercellular substance The very useful appendix on histological methods might well have included an elementary description of electron, phase-contrast, and ultraviolet microscopes The special virtue of this work remains that the text is concise, clear, and covers the subject adequately, it is very well illustrated, and stress is laid on the relation of structure to function and the dynamic aspects of histology

British Encyclopædia of Medical Practice (2nd ed London Butterworth 1957) *Cumulative Supplement* (Pp 308 35s) *Medical Progress* (Pp 339 37s 6d) (The two together cost 67s 6d)—The *Supplement* is a series of addenda to the *Encyclopædia*, designed to bring it up to date with information which "concerns knowledge of proved value, and neither controversial nor doubtful material is included" This year the *Supplement* has increased its size more than its price The companion volume contains a series of articles reviewing advances in all branches of medicine, and selected abstracts, its material is newer but more controversial

Lewis's Medical and Scientific Lending Library—The new edition of the catalogue of this library, revised to December, 1956, may now be had from H K Lewis & Co, Ltd, P O Box 66, 136, Gower Street, London, W C 1 The price is £1 5s to library subscribers and £2 2s to non-subscribers

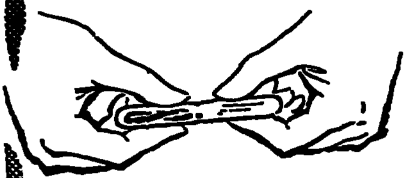
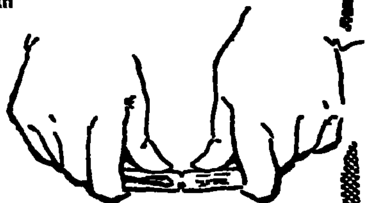
SUTURE NEWS!

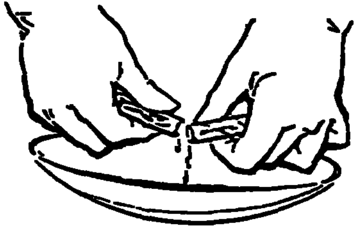
L.H.C. now in non-splintering 'Spot' Tubes



Believing in the present superiority of glass over other materials as the safest and most easily sterilised container available for sutures, The London Hospital Ligature Department has searched for some years for an improved glass tube that opens safely and cleanly We are pleased to announce that in the future, standard lines of L.H C. will be packed in our new 'Spot" Tubes



The Spot Tube is the same as a normal suture tube, but replaces the conventional scored line with a groove around the middle marked with a coloured spot. Point spot vertically down towards bowl with thumbs uppermost and break as shown below The thumbs placed about ¾" apart, must be exactly opposite to the spot to obtain a clean break the tube breaks only away from the spot Attempts to break the tube other than away from the spot will result in splintering



With London Hospital's new Spot 'Tubes no filing is needed no instruments required and it is not even necessary to hold the tube in a swab

always use London Hospital Catgut

Diabetic Arterial Disease

IN this century of medical revolutions none has been more profound than that affecting diabetes mellitus, for its treatment has been greatly improved and our concept of the disease radically altered. There is some reason to believe that the incidence is increasing in well-fed Western communities, but the expectation of life for diabetic patients—particularly the young—has much increased. Further, the actual causes of death in diabetes have changed. Before the discovery of insulin the commonest cause of death was diabetic coma, but this is now greatly exceeded by cardiovascular disorders. Today vascular disease is the chief problem in the long-term management of diabetes.[1]

It is important to differentiate clearly between the various types of arterial disease. First there is hypertensive arteriolar disease, entirely non-specific, but commoner in diabetic patients than in the rest of the population. Next there is atheroma, affecting only the arteries, and differing only quantitatively from atheroma in non-diabetic subjects. Thirdly—and the most specific—there is the capillary lesion, seen only in the unsupported vessels of the retina and renal glomerulus. Each of these vascular disturbances is quite distinct, having a different pathogenesis, a different course, and different results. Yet they may be found together, so intimately related as to confound all but the most careful inquiries into their separate natures.

Hypertensive changes are usually secondary to renal disease—most commonly pyelonephritis. Urinary infections are so common in diabetic patients that this is no surprise, even in the absence of a history of "pyelitis" or "cystitis" typical lesions are often seen at necropsy. Atheroma, too, may affect one or both renal arteries, and may cause some contributory renal ischæmia, but the resulting arteriolar lesion is in no sense specific, resembling that seen in other types of hypertension.

The incidence of atheroma in diabetic patients is undoubtedly higher than in the general population.[2] Deaths from cardiac disorders and the occurrence of intermittent claudication and gangrene are to be attributed almost entirely to this cause. WARREN and LE COMPTE[3] remark "atherosclerosis emerges without question as the leading cause of death in diabetes, accounting for over two-thirds of all fatalities." Morphologically and chemically the lesion resembles atheroma in non-diabetic patients, and is similarly associated with raised lipoprotein and cholesterol levels in the serum[4], but it tends to affect smaller and more distal vessels[2] and is differently distributed about the body. BELL[5] found that the incidence of occlusive vascular disease of the legs was increased forty-fold in diabetic patients, but coronary thromboses and cerebral vascular accidents, though also common, are not nearly as common as that. There must be some other, unknown, factor concerned with localisation. This is not to imply that the upper limbs are spared. Gangrene of the hands[6] has been recorded, and Dupuytren's contracture is common.[7] LUNDBÆK[8] has described a scleroderma-like condition affecting the hands and associated with calcification in the small blood-vessels, which, he believes, is confined to patients with long-standing diabetes. Cerebral vascular incidents, too, are common. They accounted for 231 cases in a series of 913 diabetic patients admitted with neurological involvement to the New England Deaconess Hospital between 1946 and 1951.[9] The syndrome of headaches and ocular palsies, affecting elderly diabetic patients,[10] may also have a vascular basis—probably atheroma.

The specific diabetic lesion affects only the retinal and glomerular capillaries. First thought to be discrete hæmorrhages deep in the layers of the retina, the red dots seen on retinoscopy have been shown conclusively to represent microaneurysms arising from diseased capillaries.[11] They usually coincide with a characteristic glomerular disorder, which has been described as an "intercapillary glomerular sclerosis".[12] Electron-microscopic studies indicate that the *primary* lesion may be of the basement membrane[13], it is associated with the excretion in the urine of cells containing doubly refractile lipid.[14] The retinal and glomerular capillary lesions are linked by a similarity in the histochemical properties of the hyaline material which accumulates in and around their walls, particularly with special collagen[15] and carbohydrate[16] stains. Moreover, the lesions at each of these sites has been related to certain changes in the sera—notably an increase in complex polysaccharides and glucosamine.[17 18] Possibly the relationship of capillary lesions to these substances is similar to that of atheroma to lipoproteins and cholesterol.

We still know very little of the causes and development of vascular lesions in diabetes. Yet we are not powerless to control them. There is abundant evidence

that the possibility of such complications is greatly reduced by careful control[19]—control as defined by Joslin[20] In addition urinary infections should be treated vigorously, and cryptic pyelonephritis carefully sought Infection upsets diabetic control, and hypertension increases the risks from atheroma and its complications The price of longevity is eternal vigilance

Infectivity of Virus Nucleic Acids

Two years ago we commented[21] on the work of Gierer and Schramm,[22] who had shown that the nucleic acid extracted from tobacco-mosaic virus was infective alone It was to be expected that this work would soon be followed by similar research on viruses of animals and man, and last summer two preliminary reports[23] [24] suggested that infective nucleic acid could be prepared from one of the encephalomyocarditis viruses (Mengo virus) and from Eastern equine-encephalitis virus Now comes a more detailed account by Colter et al[25] of similar investigations with Mengo, West Nile encephalitis, and poliomyelitis viruses

Colter et al homogenised cells infected with these viruses, and then extracted the virus preparations by vigorous shaking with water-saturated phenol The aqueous phase, separated by centrifugation, was designated "ribonucleic-acid solution," and such solutions were found to have an infectivity of about 0 1% of the virus homogenates from which they were prepared The next problem was whether this small residual infectivity was due to a few virus particles which had survived the extraction treatment or to viral nucleic acid First, the "ribonucleic-acid solution" was tested for protein and no detectable protein was found, but this test is not delicate enough to exclude traces of virus Indirect evidence was then sought by comparing the properties of the infective component of the ribonucleic-acid solution with those of intact virus particles Distinct differences were found The infectivity of the ribonucleic acid was inactivated by brief incubation with ribonuclease or simply by long-continued incubation at 37°C, and it was recovered quantitatively after precipitation with molar sodium-chloride solution In these respects the infectivity of the ribonucleic-acid solutions behaved differently from that of intact virus, and there was also a difference in behaviour on high-speed centrifugation Unfortunately, the two types of preparation were not compared after treatment at the same infective titre Nevertheless it seems fair to conclude that the infectivity of the ribonucleic-acid solution is not due to intact virus particles but to viral nucleic acid

The next question was whether the nucleic acid was present in the cells as such and was extracted before being built up into virus particles, or whether it had been extracted from mature virus particles Colter et al answered this question by treating cell homogenates infected with Mengo virus with ribonuclease before carrying out the phenol extraction The ribonuclease treatment had no effect on the amount of ribonucleic acid subsequently extractable from these preparations, and Colter et al conclude that the infective ribonucleic acid was extracted from the Mengo virus particles It should be possible to confirm this conclusion by experiments on purified virus preparations, as has been done with tobacco-mosaic virus Meanwhile, it seems that for a number of small animal viruses the information required to synthesise whole virus particles may reside in the viral nucleic acid alone, and on present theories of nucleic-acid structure this implies that the code for making particles of these viruses is determined by the particular arrangement of their nucleotides on the nucleic-acid chain The protein overcoat of the virus is presumably designed mainly to protect the nucleic acid in an unfriendly world, although from the point of view of the viral host the protein may have other roles But more and more attention is being devoted to understanding nucleic-acid synthesis, with a view to interrupting it where it is becoming inconvenient to man

The Open Door

During the past few years more and more doors have been unlocked in our mental hospitals So far, in setting them ajar, the emphasis has been on egress rather than ingress, but an open door should invite patients to enter as well as to leave The Royal Commission on the Law relating to Mental Illness and Mental Deficiency recognised the importance of easy two-way traffic, and many of their most important recommendations were based on the principle that the patient who is mentally ill or mentally defective should be able to get the shelter and support of hospitals and social services with as little formality as the patient who is physically ill Many of their recommendations will have to await legislation, but it is encouraging that the Minister of Health, in consultation with the Board of Control, is acting without delay on their proposals for changes in the procedure for admitting patients to mental-deficiency hospitals

It is appropriate that a beginning should be made in these hospitals, for hitherto their routine procedures for admission have been more rigid than in hospitals for the mentally ill Only exceptionally have patients been admitted without certification, and the "voluntary" procedure has not been applicable Now they will lead the way, for, thanks to the convenient wording of the present Mental Deficiency Acts, certification is not a legal necessity for these patients, and can, save exceptionally, be allowed to lapse Past official disfavour of informal admission, as the Royal Commission pointed out, was based on "considerations of administrative policy rather than law" The Minister has accordingly recommended mental-deficiency hospitals to admit patients who are willing without certification, and to review their present patients with a view to ending compulsory powers over them where possible.[1] Local authorities have similarly been asked to review patients who are subject to a guardianship order.[2]

The new procedure means that it will no longer be possible to detain these patients in hospital if they want to leave. But in fact the change will, it is hoped, be more apparent in a new climate of opinion than in an exodus of patients. In the present overcrowded state of the mental-deficiency hospitals, medical need must still be the deciding factor in obtaining admission, but patients—and, perhaps even more important, the parents of patients—will accept help more readily and more happily if they feel that they are not at the same time surrendering their rights. Some patients, especially at first, will wish to leave the hospital against advice. In these circumstances the Minister advises that they, and their relatives, should be given the opportunity to discuss the matter fully with the hospital doctor. A patient who persists in his determination to leave should normally be allowed to do so, though exceptionally in his own interests or for the protection of the public he might have to be detained by certification.

One of the most forward-looking parts of the Royal Commission's report was their concern that the mentally ill and the mentally defective should be offered more help and support as part of the community rather than as isolates in hospitals and institutions. Small hostels and welfare services would, the report suggested, make it possible for many of them to share a normal, if sheltered, life with their relatives and friends. The Royal Commission saw the local authorities as the natural administrators of such community services, and undoubtedly these patients offer the public-health doctor a big opportunity in the exercise of preventive medicine and aftercare. This work can only be effective if the mental hospitals and the local authorities draw together. The Nottingham scheme[3] and the Worthing experiment[4] illustrate some of the possibilities, and the new procedures may well provide more. For instance, in his circular the Minister asks that it should become a routine practice for the hospital to notify the local authority when a patient returns to his home. The Minister also points out that the hospital will be even more dependent on the local authority for information about the patient's background and family and for his supervision when he leaves hospital.

Everyone will be glad that it has proved possible to implement so promptly this part of the Royal Commission's report. We trust that the rest need not wait too long on legislation's more deliberate pace.

Annotations

HYPERTENSION AND UNILATERAL RENAL DISEASE

HYPERTENSION may be associated with unilateral renal disease, and in many recorded instances a sustained reduction of blood-pressure has followed selective nephrectomy, but it is often difficult to decide on the significance of kidney disease, if present, and, consequently, on the chances of benefit from operative treatment. Experimental evidence, based on the induction of hypertension by partial occlusion of a renal artery and on the demonstration of the renal pressor system, suggests that true "renal" hypertension depends essentially on a vascular lesion. This is supported clinically by the observed occurrence of hypertension in cases of renal ischæmia due either to infarction or to stenosing conditions of the renal artery and its main branches. Research in cases of hypertension of suspected renal origin has, therefore, been directed towards discovering specific vascular lesions which on identification might afford an indication for effective surgical treatment. Poutasse and Dustan[1] have submitted 109 selected hypertensive patients to renal angiography, accomplished by means of translumbar aortography.

They emphasise that aortography should be used not as a routine investigation but only in accordance with certain well-defined indications: firstly, in all cases (regardless of age or the duration of the hypertension) where there is unexplained disparity in the size or function of the kidneys on excretion urography; secondly, in all young patients in whom no other cause can be demonstrated; thirdly, where malignant hypertension develops suddenly in previously somewhat hypertensive elderly patients; and, finally, where there is rapid exacerbation of essential hypertension at any age, particularly if the patient has renal symptoms. Of the 104 patients selected according to these indications, 30 were found to have unilateral or bilateral obstructive lesions of the renal artery, which in many instances were considered to be the primary cause of the hypertension. Most of the lesions were arteriosclerotic plaques causing narrowing of the lumen and associated in some cases with post-stenotic aneurysmal dilatation of the more distal part of the vessel. 19 of these patients were subjected to operation (usually nephrectomy) with gratifying results—the blood-pressure reverting to normal in 5 out of 7 cases followed up for over a year, and in 6 out of 10 observed for shorter periods. Of the 2 patients who died, 1 had been subjected to arterial grafting and the other to attempted endarterectomy.

Discussing the significance of renal arterial disease, Poutasse and Dustan refer both to its potential danger as a cause of hypertension and to the inherent risk of spontaneous rupture of a post-stenotic aneurysm. But in deciding whether to embark on surgical treatment, it should be remembered that only a small proportion of hypertensives have vascular disease restricted to, or predominantly affecting, one kidney, and that local arterial rupture is rare. Unless, therefore, the radiographic evidence is particularly convincing, conservative management with anti-pressor drugs may seem more promising. Nevertheless, Poutasse and Dustan rightly claim that operation is indicated in carefully chosen cases, and they look forward to the time when selection will be aided by detection of renal pressor substances.

STATISTICS OF SMOKING

THERE is mounting evidence of an association between smoking and malignant and other disease, and there is a real need for dispassionate assessment of the magnitude of this association and the realities of any underlying causal mechanisms The long-term interest of the tobacco manufacturers lies in a free exchange of information between scientific workers concerned with this vital problem, and the publication of a volume of statistics on tobacco consumption[1] by the Tobacco Manufacturers' Standing Committee is a welcome token of their recognition of this viewpoint

Mr G F Todd, statistical adviser to the committee, has produced a most useful volume by collecting from various sources information on the tobacco-consumption habits of different populations both in this country and elsewhere Details are given of time trends in consumption by the type of tobacco used (whether cigars, cigarettes, snuff, or pipes) in different countries From sample surveys done by market-research firms in the United Kingdom, data have accrued on the frequency and type of smoking according to age, sex, job, and place of residence In general, these findings are in line with expectation In truly rural areas, the average daily cigarette consumption of 8 8 per man is less than the 11 3 of the county boroughs, but the lack of information on sampling procedures and size of samples makes it difficult to judge the significance of these differences Some of the other assumptions involved in calculating average consumptions are more explicitly stated in the editorial notes Despite these limitations, the general pattern of the material—e g, on the age-sex trends in smoking habits—is clear enough, and this summary should prove useful in further epidemiological inquiries

SPEEDING THE PATIENTS

YEAR by year the Ministry of Health publishes an analysis,[2] running into 47 columns, of the cost of our hospitals The hospitals are grouped, according to their function and character, under such headings as acute, mainly acute, long-stay, isolation, and mental-illness The analysis aims at providing figures to show the net weekly cost of maintaining a patient To this end the main items of expenditure are divided into two groups—those which tend to vary directly with the number of patients, and those which tend to remain unaltered by the number of beds occupied

Fallacies in the subdivisions have been pointed out in recent years, and these are recognised in the report The main distorting influence is still the assessment of outpatient expenditure This is estimated on the basis that five outpatient attendances cost the same as one inpatient day However in future more accurate information about the real cost of outpatients will be provided, for last April a start was made in the introduction of a full departmental costing system in some 200 hospitals which have an annual expenditure of £150,000 or more The figures which this new procedure will offer when the change-over is completed are awaited with interest

During 1956-57 the weekly cost of maintaining a patient in an acute hospital was £19 11*s*, compared with £17 15*s* in 1955-56 In special hospitals the cost ranged from £8 13*s* in long-stay hospitals to £23 4*s* 6*d* in isolation hospitals These figures had been adjusted (or distorted) to allow for expenditure on outpatients Last year for the first time figures were also given for the cost per patient treated in hospital These provide a telling comparison for hospitals doing the same kind of work, and are perhaps the most important part of the analysis, for they give a clue to where improvements might be made in the hospital service For 1956-57 the average cost per patient treated in "all acute hospitals" was £40 14*s*, compared with £37 12*s* in 1955-56 Generally speaking the cost per patient per week differs only slightly in similar hospitals in the same region, whereas the cost per patient often varies greatly The difference is due not to the percentage bed-occupancy but to the speed of the turnover Many hospitals have found that by careful administration the turnover can be increased without detriment to the patient's welfare, and indeed often to his advantage thanks to earlier ambulation and prompter investigations Scrutiny of the figures suggests that in many hospitals there is still scope for quickening the pace of discharges and admissions

A CANCER FALLACY

THE latest report of the National Cancer Registration Scheme[1] contains much interesting information on treatment and survival, but it also contains some surprising statements about the incidence of the disease They seem to arise from the belief that the liability of an individual to develop cancer at various ages can be deduced from a contemporary set of age-specific incidence or death rates This fallacy is well illustrated in the section on lung cancer In this disease, as is well known, the age-distribution of a large group of patients shows at present a peak in the 7th decade, and the age-specific death-rate is also lower in the 8th decade than the 7th From this the Registrar-General deduces that cancer of the lung is "a disease of middle adult life, the risk of contracting it diminishing in the older age groups", and later that the mortality-rates "justify the conclusion that in England and Wales the risk for women of contracting lung cancer does not increase after the age of 70 but much more probably falls, while after the age of 65 the risk for men certainly falls"

These statements are not supported by the available evidence It is true that the death-rate of people over 70 who die of lung cancer is smaller than the death-rate of those aged 60 to 69, and the risk of death from this cause is greater at present for an individual aged 65 than for one aged 75 But it cannot be inferred from this that the risk for the older individual was greater ten years ago or that the risk for the younger will be less in ten years' time The changing incidence with advancing age can be studied only by following the experience of a group of individuals through their successive ages In practice, this is done by the method of cohort analysis Using this technique Korteweg[2] in 1951 and Case[3] in 1956 showed that the risk of death from lung cancer increases throughout life There is, in fact, no falling off after middle life Thus, the death-rate among those now 75 is higher than it was ten years ago among the group then aged 65, of whom they are the survivors Those aged 65 at present are suffering a higher rate than were people of the same age ten years ago.

The "fall" of death-rate from lung cancer in old age is, therefore, an expression not of diminished individual risk in old people but of increased risk in the younger ones. The current death-rate among an age-group is the latest term in a series of rates stretching back year by year to the birth of all individuals in the group, and the rates may vary with, among other things, the changing environment. The individuals taking part in a contemporary age-specific rate are not the same as those in any other contemporary rate, nor can they have been subjected to exactly the same environment. In the case of lung cancer some of the relevant factors in the environment are known to have changed considerably, for the practice of cigarette-smoking increased rapidly in the early part of the century. Thus, those now 65 have been more exposed to this hazard than were those who were 65 ten years ago, and the impact of the disease on them is correspondingly greater. The application of the method of cohort analysis to cancer mortality was clearly described recently by Case,[4] who emphasised its great value as a historical or narrative technique for displaying the changing patterns of mortality.

OPERATING-THEATRES

PERHAPS the most significant change in operating-room mechanics in the past twenty years has been, in a sense, a return to Listerism. Antisepsis inculcated an aggressive approach to organisms, which were attacked even in the air; this attitude changed with the advent of asepsis to one rather of peaceful coexistence, and conveniently the hazard of airborne organisms in theatres was almost forgotten, for how could air be sterilised? Yet some remained vigilant. Hart[5] showed that hæmolytic *Staphylococcus aureus* was the predominant organism in 90% of unexplained wound infections, that this organism was not to be found in recently laundered materials, that the staphylococcus obtained from the skin and sweat of staff and patients was usually *Staph. albus*, almost never hæmolytic *Staph. aureus*, and that *Staph. aureus* could invariably be obtained from the air of the operating-room. Air contamination was worse in winter, and the source appeared to be the nasopharynges of those working in the theatre. After introduction of air sterilisation by ultraviolet irradiation, wound infection fell to a hundredth of its previous level in thoracoplasties and mastectomies. In this country Cairns[6] was concerned about airborne infection of neurosurgical cases from similar sources. But the source contaminating the air pool does not always lie within the noses of those working in the theatre. Sevitt[7] found that two cases of tetanus were due to introduction into the theatre of spores from plaster hair being used for building repairs nearby; he indicted the ventilation system, and yet had the discouraging experience four years later of having to report gas-gangrene infection due to the still faulty system.[8]

Except for a few hospitals equipped with the plenum heating system, the standard ventilation system during half a century of asepsis has been on the exhaust principle in order to get rid of steam from the sterilisers and to provide comfortable working conditions for surgeon and staff; air is changed by extraction. The possibility that organisms from outside the theatre might thus be sucked in was long ignored, and so the great majority of our hospitals today, even those built just before the late war, have to face a new era of infection with dangerous equipment. A bulletin just published by the Ministry of Health,[9] the first of a series to help those concerned with designing and planning hospitals, is particularly welcome since it recognises the *volte-face*—the return to the attack on airborne organisms. Both ultraviolet radiation and aerosols are dismissed as means of air sterilisation. Instead it is recommended that positive-pressure systems of ventilation be installed in all new theatres so that organisms shed within the theatre are blown out, while dust and organisms outside are driven away from its precincts. But installing a positive-pressure system cannot alone ensure security,[10] since the current of air may disturb dust lying on the floor; its direction must be controlled in the light of smoke tests. Moreover vertical shafts connecting suites of theatres tend to develop into extraction systems owing to a Venturi effect as warm air rises up them, thus nullifying the attempt at positive pressure—yet another reason for constructing theatre suites in horizontal, as the bulletin recommends. There is one quite important omission. Sometimes people outside the theatre—usually members of the medical staff—need to speak to the surgeon while he is operating. This is best done by means of microphone and speaker circuits, which obviate disturbance due to movement in and out of the theatre—movement which Bourdillon et al.[11] have shown to be followed by an increase in airborne organisms.

One innovation in the layout of the theatre suite is the inclusion of a recovery room—an admirable recommendation which may nevertheless evoke controversy. All would agree on the need for a site to be set aside where the anæsthetist may readily reach the patient who has just been operated on, while still conducting the rest of the operating-list; a third of all anæsthetic deaths occur within half an hour of the end of the operation, and these are almost invariably due to obstruction of the airway. But some would remove the recovery room from the theatre and place it, as a recovery ward, immediately adjacent[12]; they insist on the need for such a ward not only for immediate postanæsthetic care but for the first two or three days after operation when the patient can (it is claimed) be better treated in this special ward and the staffing of the ward he has come from can be correspondingly lightened. Recovery wards are the vogue in the New World, where they doubtless help to reduce the handicap of the scarcity (even greater there than here) of experienced nurses. Where this scarcity is not so great, the other practical advantages of concentrating postoperative patients in a single ward must be set against the disadvantage of requiring them to enter a new environment at a time of special stress. Any patient coming into hospital is quite suddenly alone, with human contacts—those stabilising factors in life—severed. Accordingly he must set about establishing new contacts, with the staff and his fellow patients. To the surgical patient the new contacts that he establishes before operation are especially valuable in the first few postoperative days.

Public Health

PROBLEM FAMILIES

A London Survey

J A Scott
O B E, M D Lpool, F R C P, Q H P
MEDICAL OFFICER OF HEALTH FOR THE COUNTY OF LONDON

The Minister of Health in 1954 encouraged local health authorities to develop their work in preventing the break-up of families, and in particular to see what they could do to break the vicious circle in which problem families tend to reproduce themselves in the next generation—at an expense to the community out of all proportion to their numbers He suggested that this work might be done through the redeployment of existing health visitors rather than by an increase in their number, but the employment of a trained social worker might be useful

Our first task in London was to ascertain how many families needed help on the lines suggested, and to estimate how many needed intensive care which could be undertaken only by a case-worker with a small case-load or by a combination of social case-workers With my colleagues in the education and welfare departments a survey was made covering all families with a child or children under the age of 15 My department investigated the families in which there was a child under 5 living at home, the education department investigated those in which all the children were older, and the welfare department dealt with families in homeless-family units or halfway houses So far as numbers are concerned, therefore, the data given are complete, but the detail relates only to the families with which my department was primarily concerned

Planning

Families may be classified broadly into five groups

1 Above normal visiting standard
2 Socially sound
3 Families with difficulties
4 Potential problem families
5 Hard-core problem families

The survey was concerned with the selection of these two last groups

Potential problem families may be defined as "those in which there are early signs of failure which may lead to disruption of normal home life with consequent risk to the children", and hard-core problem families as "those which are unable, by their own efforts to raise themselves from the state into which they have fallen or to take advantage of the social services of which they are in need" There are, however, many other definitions, and it was felt that any inquiry based solely on qualitative criteria would lead to subjective assessments by health visitors and others, from which no valid conclusions could be drawn Accordingly the factors which were likely to be found in such families were listed and points allocated to each factor this provisional pointing system was tested by application to the circumstances of a number of families and modified in the light of the tests The factors and points awarded them were chosen arbitrarily, but they provide a clear and uniform basis for a survey, moreover they enable comparable assessments to be made in later years A maximum of five discretionary points was allowed for imponderables

The list of factors and the points awarded are set out below, for brevity certain detail has been omitted, such as guidance on the interpretation of the terms drinking, gambling, and promiscuity as factors, and the period over which they should have been operative

FACTORS LIKELY TO BE FOUND IN PROBLEM FAMILIES

1 *In a parent*
  (a) Low intelligence or mental deficiency
  (b) Mental illness
  (c) Physical handicap or illness which prevents work or permits of light work only—e g, tuberculosis, heart-disease
  (d) Long-continued or recurrent unemployment of main wage earner from other causes than physical handicap or illness
  (e) Excessive drinking
  (f) Excessive gambling
  (g) Sexual promiscuity
  (h) Serving, or has served, a prison sentence
  (i) Suspected cruelty to or neglect of children
  (j) Known cruelty to or neglect of children

2 *Other parental shortcomings*
  (a) Persistent quarrelling
  (b) Failure to call doctor for major illness
  (c) Leaving young children unattended

3 *In a child*
  (a) Repeated hospitalisation of one or more children for gastroenteritis or respiratory disease, or two or more children for minor accidents
  (b) Persistent truancy
  (c) Juvenile delinquency (court cases only)
  (d) Attendance at child guidance clinic
  (e) Under Probation Officer or committed to care by a court

4 *Housing*
  (a) Statutory overcrowding
  (b) Living in intolerable conditions (while not overcrowded) because of either lack of amenities such as piped water, damp or insanitary conditions, and/or enmity of other occupants of dwelling

5 *Poverty and mismanagement*
  (a) Chronic family debt
  (b) Lack of minimal necessities of furniture and bedding
  (c) Inadequate and irregular meals
  (d) Domestic filth and disorder
  (e) Wilful damage to property
  (f) Lack of, or inadequately maintained, clothing of children

6 *General*
  (a) Unnecessary crowding at night
  (b) Gross personal uncleanliness
  (c) Failure to take advantage of necessary help and service proffered.
  (d) Child or children taken into care other than as the result of court action, and who are frequently taken into or out of care

Allocation of Points to Factors

1 1 point was allotted for the existence, whether one or more persons was affected, of each factor in the list, except in section 1, where for items (*a*) to (*i*) the pointing was

For one parent—1 point
For both parents or the sole parent—3 points

and for item (*j*) the pointing was

For one parent—$1^1/_2$ points
For both parents or the sole parent—4 points

2 Additional points or fractions of points, up to a maximum of 5, could be added by the reviewing officer to deal with imponderable factors not listed—e g, persistent sickness of children, mental or physical cruelty of one parent to another, racial differences between parents, spasmodic reappearances of deserted, divorced or separated parent (which upsets stability), a combination of items which do not of themselves merit points, such as domestic disorder (without filth), poverty with spasmodic debt, large numbers of children under 5, and inadequate (but not irregular) meals

3 The maximum pointing was 56, and for the purposes of classifying the families assessed the following arbitrary values were used

Hard-core problem family—11 points or more
Potential problem family—5–10 points inclusive

The differing social conditions in various parts of the county, and the lack of any real knowledge of the numbers and location of problem families, made it necessary to have a complete survey rather than a sample

Operation

The county comprises nine divisions, each administered by a divisional medical officer In each the health visitors were asked to make a provisional selection of potential and hard-core families from their total case-load (in London a case-paper is made out for every child born to a resident and is kept in a family folder at the local clinic) Family case-histories, selected by the health visitors and supplemented by discussion, were considered by the divisional nursing officers in each division (who were appointed reviewing officers) to assess the factors and to grade the families Health visitors made a note of the time actually spent for a period of four weeks on the families finally selected Finally a central team (Principal Medical Officer (Maternity and Child Welfare), Statistician, and Chief Nursing Officer) visited a number of centres in the divisions and interviewed the health visitors Ten centres were visited and 39 health visitors were interviewed The centres were chosen to represent a cross-section of the London population as regards social class

The relationship of health visitors with other field workers of both voluntary and statutory bodies called in to assist the family, the attitude of the family towards advice and help, and the limitations imposed by their willingness or ability to accept advice, were all taken into consideration in forming an estimate of the amount of time which should be spent on these families

Numbers

Families with a Child under 5

Table I sets out the number of families surveyed by the public health department The figures shown tend to be an underestimate, because constant immigration means that at any given moment there will be new families in the county whose circumstances are not fully, if at all, known, moreover, with the turnover of health visitors, there were some who, at the time of the assessment, could judge only from case papers, which, however well kept, are no real substitute for personal knowledge of the family

The difference between the average and maximum numbers of problem families in the care of a full-time health visitor confirmed the impression that problem families tend to be grouped in small areas

Also they tend to move about for example, of 30 families in the case-load of one health visitor, 6 had moved out of her district in three months They may also move in and out of the various categories as their circumstances change for example, in one division there were at the time of the survey 314 problem families in all, whereas six months later the total had fallen to 303 The net fall of 11 families was made up of a much larger fall in the number of potential problem families offset by a rise in the number of hard-core problem families

TABLE I—NUMBERS AND PERCENTAGES OF PROBLEM FAMILIES IN FAMILIES WITH CHILD UNDER 5

No of families surveyed	with children under 5 only	103,172
	with schoolchildren also	68,699
	total	171,871
No of potential problem families	among those with children under 5 only	569
	among those with schoolchildren also	1225
	total	1794
No of hard-core problem families	among those with children under 5 only	146
	among those with schoolchildren also	516
	total	662
Percentage of potential problem families of	those with children under 5 only	0 55
	those with schoolchildren also	1 78
	all families surveyed	1 04
Percentage of hard-core problem families of	those with children under 5 only	0 14
	those with schoolchildren also	0 75
	all families surveyed	0 39
Percentage of problem families of	those with children under 5 only	0 69
	those with schoolchildren also	2 53
	all families surveyed	1·43
Average no of problem families in the care of a full time health visitor	potential problem families	4
	hard-core problem families	2
	all problem families	6
Maximum no of problem families in the care of a full time health visitor	potential problem families	27
	hard-core problem families	18
	all problem families	33

The 171,871 families surveyed which have a child or children under 5 comprises, as far as can be estimated, virtually the total that exists

Our belief that in this respect the survey was almost complete is supported by the results of an earlier investigation in which the number of children under 5 with whom the health visitors were in contact was compared with the Registrar General's population estimate, and with a current estimate of the number of families of differing compositions, taking into account migration and birth and death rates The number of problem families ascertained is unlikely to be too few, since these families are characterised by their demands, voluntary and involuntary, on the social services

The rates for the two categories of problem family combined ranged from 0 52% in division 7 (Camberwell and Lewisham) to 2 28% in division 5 (Bethnal Green, City, Poplar, and Stepney) the county average was 1 43% The estimated percentage of problem families, based on an investigation of 1000 families in Newcastle upon Tyne, was 2, but, as the authors of the report[1] make clear, " the difficulties of measurement and the way the families were selected should be borne in mind " In a large urban county such as London, which contains within its boundaries such widely differing types of locality, larger interdivisional differences might have been expected, but in fact the percentage incidence of problem families in the remaining seven divisions ranges from 1 04 to 1 80

The lowest figure merited further investigation Possibly it was attributable to the stable staffing in the division concerned, moreover, for a long period the senior nurses had given positive direction to the work with these families, and home helps had been used to assist in more intensive efforts in the homes

As might be expected, there were fewer hard-core problem families than potential problem families—662 as opposed to 1794, and in both the potential and hard-core groups there were fewer families among those with children under 5 only than families with children under and over 5—in total 715 as opposed to 1741—although there were only 69,000 mixed families compared with the 103,000 families with children under 5 (Despite fluctuations in numbers these findings are consistent among all divisions) Among families with a child or children under 5 years of age the percentage incidence of potential and hard-core problem families was 0 55 and 0 14 respectively, among families with children both under and over school age the corresponding percentages were 1 78 for potential and 0 75 for hard-core problem families It is assumed that the reason for the higher percentages of problem families among the " mixed " ones is that they are probably larger and/or poorer so that the mother cannot cope—there seems to be a limit to the difficulties with which a stable but dull parent can compete, after which one further adversity will produce a complete breakdown in domestic management

Families with no Children under 5

Among the families cared for through the education care-committee organisation were 427 potential problem families and 99 hard-core problem families

It is proper to note that an attempt had to be made by the care-committee organisers to award points for the various factors as revealed by the case-histories in the office files, and, whereas the families where children had been reported to the

TABLE II—TOTAL NUMBERS OF POTENTIAL AND HARD-CORE PROBLEM FAMILIES

Problem family	Children under 5 only	Children under and over 5	Children all over 5	In welfare homes	Total
Potential	569	1225	427	18	2239
Hard-core	146	516	99	22	783
Total	715	1741	526	40	3022

National Society for the Prevention of Cruelty to Children (N S P C C) or the Education Officer's Problem Case Conferences were reasonably well documented, full data were not usually available in other cases The assessment of families into the two categories was therefore somewhat subjective

The percentages, based on an estimated number of families, were 0 21 for potential and 0 05 for hard-core problem families The rate for both (0 26) is about two-fifths of that for families with children under 5 years only and a tenth of that for families with children over 5 also

As the families reported on by the care organisers were not increasing and the children were all benefiting from the school and school-health services it might have been expected that the percentage would be below that for the mixed families The numbers reported may, because of the reliance mainly on case papers, be an understatement—i e , in some households in which the children are all of school age—the mothers' responsibilities are lessened and the more obvious evidence of neglect may tend to disappear, but other manifestations, such as truancy or juvenile delinquency are apt to take their place, while such factors as low intelligence or housing difficulties remain

Families in Homeless Family Units and Short-stay Accommodation

Within this select group of families, the wardens of the homeless family units chose those which appeared to come within the definition of potential and hard-core problem families There were, in a total of 645 homeless families, 18 thought to be potential and 22 hard-core problem families In terms of percentages, therefore, potential problem families amounted to 2 8 of the total, hard-core families to 3 4, and the two together 6 2 These figures are obviously not comparable with those obtained by more exact standards, but the incidence of problem families so selected was slightly more than four times as high as that ascertained in the public-health department of families living in their own home

TABLE III—PERCENTAGE INCIDENCE OF FACTORS AMONG ABOUT 1000 PROBLEM FAMILIES WITH A CHILD OR CHILDREN UNDER 5

Factor	Potential problem families	Hard-core problem families	All problem families

Imponderable factors	76 1	59 3	70 3

Total Numbers

From all departments, there was reported a total of 3022 families, 2456 from those with a child or children under school age, 526 from those with children of school age only and 40 in welfare establishments (table II)

In five recent surveys in other parts of the country,[2] the figures of incidence range from 1 2 to 6 2 problem families per 1000 total families The bases of the various inquiries were not uniform, and the figures should be treated with some reserve There are in London some 1,100,000 families, but only about 400,000 of them have a child or children under 16 The London total works out at about 2 75 problem families per 1000 total families, though, as will be apparent from what has been already said, the various components of the total number were not all arrived at in quite the same way, and more reliance can therefore be placed on some than on others

Ætiological Factors

After the survey was well advanced it was decided to analyse the ætiological factors in problem families in four divisions The number of problem families reviewed was about 1000 and the factors assessed are shown in table III

There were, as might be expected, a number of differences between the divisions in the incidence of such factors as long unemployment or lack of amenities The table again separates the families into the potential and hard-core categories a further subdivision was made into those with all children under five years of age and the mixed families, but this has been omitted from the table, largely because nothing of importance was revealed

The salient features are, first, the high amount of emotional instability—if it be accepted that excessive drinking, excessive gambling, sexual promiscuity, and persistent quarrelling are symptomatic of instability 54 5% of potential problem families and 71 6% of hard-core problem families reveal emotional instability by one such symptom The second feature is the high incidence of low intelligence or mental deficiency 42 2% of the potential problem families and 67 3% of the hard-core (It is admitted that low intelligence has not been defined and is therefore a matter of judgment of the individual health visitor)

It is a matter for conjecture whether anything substantial can be done through the normal health services for the families in which emotional instability is combined with low intelligence This group accounts for 19 1% of the potential problem families and 45 8% of the hard-core, but instability, as evidenced by the four symptoms chosen, is in fact combined with normal intelligence or above in no less than 35 4% of the potential problem families and 25 8% of the hard-core

The third feature is the proportion of families in which there was known or suspected cruelty or neglect Allowing for overlapping, in that some families had both, say, known neglect and suspected cruelty, the percentages were 34 6 in the potential problem families and 77 1 in the hard-core Within this group there are families in which neglect may amount to cruelty, yet the family remains an entity because there is affection between parents and

TABLE IV—TIME SPENT BY HEALTH VISITORS ON PROBLEM FAMILIES WITH A CHILD OR CHILDREN UNDER 5

—	Minutes per week per family			Total hours per week
	Average	Maximum	Minimum	
Potential problem families	20	270	0	606
Hard-core problem families	28	210	0	308

children This is not, of course, a matter which affects local authorities alone—many of the families being under the scrutiny of the N S P C C or the probation service Nevertheless the figures are profoundly disturbing

The fourth feature is the environment housing, there were overcrowding or intolerable conditions (including enmity of neighbours), or both, in 44 3% of potential problem families and 60 2% of the hard-core, allowing for overlapping Whether bad housing dragged the family down, or whether the unsatisfactory family inevitably gravitated to bad conditions is a matter which can be decided only after careful sifting of the individual family circumstances

Finally, 30 4% of the potential problem families and not less than 51% of the hard-core failed to take advantage of the help and services proffered

Time Spent by Health Visitors

Table IV shows the average time spent per problem family per week by health visitors, together with maxima and minima

The county averages were twenty minutes a week for a potential problem family and twenty-eight minutes for a hard-core one In every division of the county more time was spent on the hard-core than on the potential problem families The maximum times are almost without exception the result of a crisis in one or more of the families concerned—such as a mother temporarily deserting her children, an economic crisis, infidelity, a child being in trouble for truancy, assault or theft, or illness in a parent—which has caused the health visitor to devote perhaps the whole of her time for several days to solving the particular issue

It may seem surprising that the minimum times are nil, but this is due to such causes as the absence of the family (hop-picking), the temporary stability of the family, or the occasional unwillingness to accept the health visitor The fact that a visit would be unwelcome does not mean that the family is neglected Quite apart from information garnered from other social workers, health visitors learn a great deal about their families as they go about their district which is not reflected in the times recorded they may meet the mother in the street or the children at school, they see friends, neighbours, and relations, and some mothers will seek out the visitor at the centre when they are in trouble Another reason for low times spent is that, as was shown in table I, a few health visitors had to deal with a concentration of problem families—a concentration too great in some cases for them to carry adequately The information revealed by the survey has led to a certain amount of " load spreading " It is impossible wholly to equalise this particular burden because of the location of the families and the demand of other duties undertaken by health visitors Again health visitors do not work in isolation almost always there were two or more social workers dealing with a problem family, and if they are working together responsibility is shared and visits by either one become less frequent

A decision of the average amount of time that could usefully be spent on families in the two categories was a matter of some complexity There were variations in family customs, outlook, size, age, structure, housing, and so on, as well as constantly changing family circumstances In some cases Family Service Units are actively engaged in work with problem families as well as the Family Welfare Association, N S P C C, Area Children's Officers, &c a service of specially trained home helps has recently been introduced to work with the health visitors Moreover, the practice has been developed of health visitors working in teams, which has led to a pooling of ideas, abilities, and experience (not least in the linguistic and religious fields), and has enabled families to be transferred from one health visitor, with whom they may no longer be en rapport, to a colleague on the team this teamwork has provided for an easier transference of care in times of staff sickness and a means of overcoming the feeling of staleness that overtakes at times even the most enthusiastic of workers In addition, where the father was the stable element in the household, the health visitor has made contact with him in the evenings or at weekends the need for a male worker has been apparent in cases where the father has been recalcitrant or sexual problems have been involved, and, in these circumstances, health visitors have sought the aid of male workers of the N S P C C or National Assistance Board The general practitioner can be immensely helpful when an authoritative approach to the father is required

There is a wide range of times about the averages (table IV), and the maximum times are themselves averages of time spent on the families in the care of an individual health visitor, in short it seems that when a family was known to be going through a period of crisis, additional time was given by the health visitor, though possibly at the expense of other duties

It is clear that more time could usefully be spent on both categories of problem family than the averages of twenty and twenty-eight minutes a week Extra time is required to rehabilitate some families where intensive help is needed But the number of health visitors is unlikely to increase much in the near future If such selected families could be passed to social case-workers, who might *on average* give up to ninety minutes a week to them, some progress might be made The health visitors would, of course, continue to visit on health aspects, but would be relieved of the intensive case-work on these selected families The time thus saved by the health visitors could be devoted to the balance of problem families for which they are responsible

Summary and Conclusions

The prevalence of potential and hard-core problem families has been surveyed in the nine divisions of the county of London The total number of such families ascertained was 3022 Of these 2456 had a child or children under 5 526 had children above that age, and 40 were in welfare establishments

The following figures refer to families with a child under 5

1 The percentage prevalence in the divisions for both ranged from 0 52 to 2 25, with a county average of 1 43 (if these extremes are ignored the range was from 1 04 to 1 8)

2 An analysis of ætiological factors in 1000 families revealed emotional instability in 54 5% of the potential and 71 6% of the hard-core problem families, low intelligence or mental deficiency in 42 2 and 67 3% respectively, known or suspected cruelty or neglect in 34 6 and 77 1%, overcrowding or intolerable housing conditions in 44 3 and 60 2%, failure to take advantage of help and services proffered in 30 4 and 51 0%

3 The average amount of time spent weekly by a health visitor in London was twenty minutes per potential problem family and twenty-eight minutes per hard-core problem family

4 If social workers could be employed for time-consuming case work on selected families, an additional effort could be made to rehabilitate these families, and the health visitors would be relieved to that extent of their responsibilities, although continuing to visit on health aspects The time saved by the health visitors could be devoted to the remaining problem families

To test the advantages of using social workers in this way, they have now been given the main responsibility for the support of a number of selected families

Many hundreds of my colleagues—doctors, nurses, administrators, and statisticians—have taken part in this investigation I am indebted to them all, and in particular to Dr M MacGregor, Dr D Egan, Mr G Berridge, Mr C W Shaddick, and Miss E Robinson

LONDON'S HEALTH IN 1956

There was no startling change in the health of London between 1955 and 1956 [1] Dr J A Scott, the county medical officer of health, records that in 1956 the infant and maternal mortality rates reached new low records, the death-rate and notification-rate for tuberculosis continued to fall (for the first time on record no male under 25 died from pulmonary tuberculosis), but notifications of dysentery were the most numerous on record The illegitimate live-birth rate (8 5 per 100 live births) was by far the highest since the war-years' average of 8 4%, and the suicide-rate rose from 0 14 to 0 15 per 1000 (since 1920 it has varied from 0 11 to 0 15)

Public-health work is today extending its scope to encompass attempts to prevent mental illness, respiratory disease (through attacking air-pollution), and home accidents, all of which are common causes of death and disability The three appendices to the report are thus of special interest

The first concerns "problem families"—i e, those who have not responded to the general improvement in social conditions and cannot by themselves improve their position or make use of social services Children of such families are prone to physical neglect and mental disturbance The appendix sets out the services dealing with problem families and reports a survey (described by Dr Scott in an article on p 204 this week) made to discover the number of potential and hard-core problem families—together these comprised 1 43% of the families in the county, with figures ranging from 0 5% in one division to 2 2% in another

The second appendix describes investigations that sought to discover links between atmospheric pollution and mortality from respiratory disease At 7 recording-stations, the smoke and sulphur-dioxide content of the air were measured in the winters and summers of two years, the measurements and some other factors (social class, percentage of residents born in London) were compared with the death-rates from respiratory and other diseases Dr Scott sums up the results thus

> "The bare fact of long residence in London appears to be likely to increase the risk of dying particularly from bronchitis, the effect of a smoky atmosphere is also to increase the risk but while a brief sniff of sulphur dioxide is not particularly harmful the dual effects of both high pollution and long residence in London are associated with high mortality Association is, however, not necessarily a matter of cause and effect The reason for the poor numerical association of mortality with the indices of atmospheric pollution in [various areas of] London may be that the differences within London are not sufficiently large to demonstrate any difference"

During fog, acute "smog incidents" with many deaths were likely when the pollution of the air reached a threshold of four times the normal winter level

In his third appendix Dr Scott points out that the total number of deaths from home accidents rose by about 25% between 1950 and 1955 The small decline in deaths from suffocation and in deaths of young children was more than offset by the increase in deaths from falls, poisoning, and burns, and in deaths in old people The causes of accidents are broadly inexperience in the young, inattention in the adult, and infirmity in the elderly Safety devices, such as fireguards, even when properly used are only a partial and temporary substitute for constant supervision of children The appendix sets out methods of instruction in home safety, including exhibitions, school, newspaper, and cinema publicity, and the training of home nurses and health visitors

The Wider World

SCHISTOSOMIASIS IN CHINA

BRIAN MAEGRAITH
M A, D Phil Oxon, M B Adelaide, F R C P, F R C P E
PROFESSOR OF TROPICAL MEDICINE, SCHOOL OF TROPICAL MEDICINE, LIVERPOOL

SCHISTOSOMIASIS* is regarded as the most serious parasitic disease in China Its extent is not yet fully known, but in the area of the Yangtse valley and the rich lands to the south recent surveys have revealed over 11 million persons infected, and local infection-rates ranging from 10% to 70%

The physical consequences of schistosomiasis in the individual sufferer are often savage, as will be seen below, but the effects on the community as a whole are even more disastrous, since it has been estimated that the disease, which is manifest particularly in young adults and in middle age, reduces the working capacity of those affected to well below half normal

In a predominantly farming community the economic significance of this incapacity is immense As the population grows increasing pressure is brought to bear on the farmers to produce more food To do this they must be able to work at their top capacity, which demands good health It is not surprising, therefore, that China is turning all her available resources to checking clinical schistosomiasis, and controlling its transmission

A nation-wide scheme of control has been evolved within the last two years and is now in operation and expanding rapidly The two main points of attack are (1) the mass treatment of overt infections with the object of bringing clinical relief and reducing the output of infective *Schistosoma japonicum* eggs in the fæces, and (2) the control and eventual elimination of transmission by preventing the pollution of water by human and animal fæces containing ova and by destroying miracidia and cercariæ and the amphibious intermediate snail host oncomelania

The development and progress of the scheme is the political responsibility of the Ministry of Health in Peking, which works through a small executive lay committee and associated technical groups in Shanghai In the twelve provinces concerned antischistosomal centres with trained staff have been established for purposes of mass treatment, propaganda, and training of local recruits and for the general administration of regional control Subsidiary units have been created in the smaller districts right down to the villages and cooperative farms The actual field work at this level is done by the local farming or village communities, who have among themselves organised trained teams for controlling transmission within their own territories In this way the local community is acting for itself in its own interests and cooperating at the same time in the wider national scheme

The Chinese Government quite rightly regards propaganda as an essential technique in the antischistosomal scheme and has organised public information services in the endemic areas on an impressive scale, with the twofold object of achieving control of the disease and of obtaining a more general improvement in social health and cleanliness and, even more important, a genuine desire for an improving standard of living Working through radio, village communal news-sheets, talks, cinemas, and village committees (often containing a member of the Communist Party), the propaganda is persistent and all-pervading and is clearly getting results, some of which, such as the astonishing control of flies and litter, are immediately obvious to the visitor

In effect, " this nation-wide campaign, unparalleled elsewhere in the world, has brought about great improvement in personal hygiene and environmental sanitation and is instrumental in helping to eliminate conditions under which diseases like schistosomiasis are disseminated " (*Chinese Medical Journal*, 1955)

The cooperative effort demanded in such a campaign is not limited to the relations between the people and the health authorities only Active help and advice are needed in addition from allied services, including agriculture, forestry, and water conservancy, for carrying out vital operations such as draining, ditching and reclamation of low-lying land, especially in potential flood areas The remarkable degree of integrated cooperation already achieved, perhaps more easily in China than in non-totalitarian countries, augurs well for the future success of the whole scheme

The Chinese have set as their target the practical control of schistosomiasis within twelve years from now Their cooperative enthusiasm, skill, and dedication to the task should enable them to achieve this objective

During a recent visit to China with a group of doctors from the United Kingdom I was fortunate enough to see a good deal of the antischistosomal scheme in operation and had opportunities to study the disease itself I have set down below some of my impressions and some of the information I obtained in the hope that this monumental modern struggle against an ancient disease will interest and excite you as much as it did me

Clinical

The development of the signs, symptoms, and complications of *S japonicum* schistosomiasis has often been described, and, on the whole, most of the advanced cases I saw conformed to the expected patterns There were, nevertheless, numerous interesting points- which were emphasised by our Chinese colleagues

EARLY CASES

It was surprising to find, even in heavily endemic areas, patients with relatively recent infections, in whom a single short period of exposure to cercariæ could be clearly ascertained Many of these early cases had high irregular fever Some had diarrhœa but others experienced no gastrointestinal symptoms except anorexia Tenderness over the right upper half of the abdomen was common and in some cases the liver was tender and easily palpable one or two fingerbreadths below the costal margin The results of " liver function " tests were usually within normal limits

The clinical condition became very severe in some cases soon after the onset, with high intermittent or remittent fever, a notably enlarged and tender liver, and the development of a typhoid-like state A few developed cough and mild pulmonary changes

Early cases usually responded well to intravenous potassium antimony tartrate therapy Some, however, developed temporary pulmonary lesions during treatment which could be identified clinically and radiologically and which resembled in many respects those reported in other schistosome infections The clinical picture is familiar to Chinese physicians but is probably not so well known elsewhere It may therefore be of interest to summarise an example recently described by Dao Chin and others (1956)

The patient was a 16-year-old boy admitted three months after exposure to infection He had had irregular fever for ten days There was some tenderness in the right upper abdomen, but otherwise physical examination, including X-ray of the chest, revealed nothing abnormal, *S japonicum* ova were found in the stool The fever subsided slowly under potassium antimony tartrate therapy, but on the thirty-fourth day of treatment (after a total of 0 96 g of the drug) fever reappeared and the patient developed paroxysms of coughing without sputum There were some rales over the bases of the lungs and X-ray of the chest revealed extensive bilateral miliary lesions, especially in the lower lung lobes The patient did not feel ill and spontaneous recovery took place after a few days Six weeks later the lesions were still present but clearing

The characteristic features of this syndrome, which also appears in chronic cases, were the fever and cough developing towards the end of antimony therapy, the miliary infiltration and patchy consolidations in the lungs, the continued well-being of the patient and the self-limited course These peculiar pulmonary changes are believed to arise from fresh dissemination of ova to the lungs or from allergic activation of existing circumoval lesions

The severe pulmonary complications which occur in late *S mansoni* infections and lead to cor pulmonale seem to be rare in *S japonicum* infections even in cases with extensive hepatic and splenic involvement

COMPLICATIONS

Gastrointestinal complications are common in late japonica schistosomiasis, The lesions, which include polyposis, hypertrophy, and fibrosis of the colon and rectum, are similar to those seen in *S mansoni* infections The same is true of the liver and spleen involvement The cases I saw in the Endemic Diseases Hospital in Shanghai, for instance, closely resembled those distressing examples of late *S mansoni* infection so common in lower Egypt

The abdomen was distended with fluid and the superficial collateral venous vessels were very prominent (fig 1) The liver was usually large and firm but occasionally not enlarged The spleen was invariably enlarged, sometimes enormously so There was extensive œdema of the legs and the back

In cases associated with fibrotic changes in the liver, portal hypertension had developed with extensive abdominal collateral circulation Varicose œsophageal veins could often be demonstrated radiologically, but hæmorrhage from these vessels was apparently relatively infrequent Severe and catastrophic bleeding did sometimes occur, however, usually from rupture of varices of the basal gastric veins

These advanced signs were found in young to early middle-aged adults with long histories of exposure to infection, stretching in some cases over many years Most of the patients were

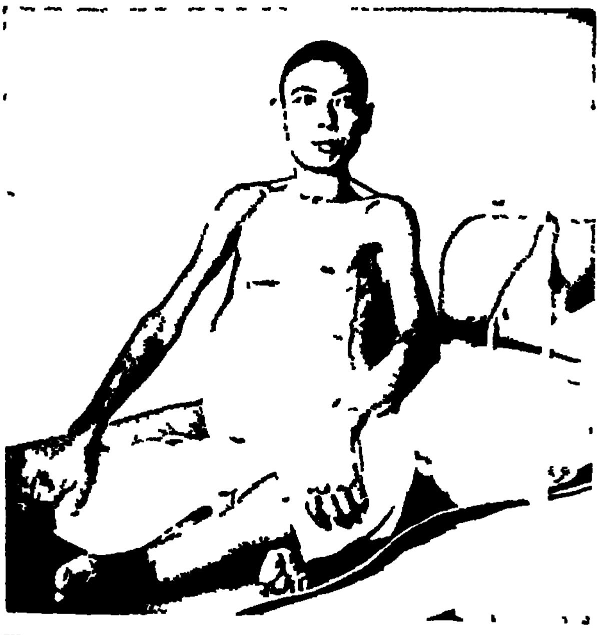

Fig 1—*S japonicum* infection with hepatic cirrhosis, portal hypertension, and ascites. Note the prominent superficial veins.

men, probably because of their greater risks of exposure There was no satisfactory information about the relation between the development of the complications and the intensity of the infection

Similar liver damage and fibrosis with ascites and portal hypertension and enormous enlargement of the spleen occur in older children, sometimes associated with pronounced dwarfism and retardation of sexual development Dwarfs of this sort were in evidence in several of the rural treatment centres I visited in the highly endemic areas Some had shown considerable improvement with antimonial treatment

The pathogenesis of liver lesions is still not fully understood, but the indications are that egg deposition plays a more significant part than the presence of the adult worms Thus, bisexual infections in mice and rabbits have been shown to produce much more severe pathological liver changes than unisexual infections, and intrahepatic injection of eggs more serious effects than injection of adult worm extracts, including infiltration of the connective tissue of the portal tracts and periphlebitis of the portal venules Changes in the vascular pattern of the portal tracts such as described by Bogliolo (1957) in human *S mansoni* infections have not been recorded

THERAPY

No entirely satisfactory chemotherapeutic agent with suitably low toxicity and high efficiency has yet been discovered

There is general agreement that the best results are obtained by the parenteral administration of trivalent antimonial compounds, of which potassium and sodium antimony tartrate are considered the most effective and are most commonly used These drugs are toxic and serious side-effects may develop even with carefully graded dosage The therapeutic activity and toxicity of a given course of treatment have been found to run parallel to the amount of antimony administered Contrary to widely held European views, no difference in toxicity has been observed between the potassium and the sodium salt, the former of which is in general use

Certain other antimonials, such as antimony gluconates, citrates, and guanides, are also active against the infection but for reasons of expense or toxicity are not favoured clinically

The results of oral therapy have not been encouraging Potassium antimony tartrate is the only antimonial which has been found to have some effect by this route (about 60% of its parenteral activity) Lucanthone (' Miracil D ') and certain acridine derivatives have been found ineffective clinically and experimentally

Studies in animal infections have indicated that the duration of the infection has little influence on the therapeutic effect of potassium antimony tartrate The interruption for a short time of a course of therapy and its subsequent completion has no obvious effect unless the interval is long On the other hand, full dosage given a long time after an inadequate course is not always effective, suggesting the development of some drug resistance

The necessity for better and safer drugs has led to extensive research in which many natural and synthetic compounds have been examined either clinically or in laboratory infections in mice, rabbits, or dogs In animal infections the most active antimonial has been found to be ammonium antimony gluconate, but this compound, which has about the same toxicity as potassium antimony tartrate, has not yet come into extensive use Compounds containing mercury, tin, and acridine dyes have proved largely ineffective So have derivatives of the diaminodiphenoxy-heptanes and hexachlorethane, a drug successfully used by the Russians for the treatment of opisthorchiasis

TREATMENT OF JAPONICUM INFECTIONS

Length of course (days)	Total dosage mg per kg body-weight)	Method *	Relapse-rate † (%)
1	8	3 doses, one every 3 hours	60
3	12	1 dose every 12 hours	32
7	15	1 dose daily	15
20	25	1 " "	15
25	30	1 " "	16

* In the 1-day, 3 day, and 7-day courses the drug was made up as a 1% solution in 25–30% glucose In the longer courses the glucose was sometimes omitted Each dose was given very slowly Maximum single dose 20 ml of 1% solution

† Techniques described under the section ' Results '

Chinese native herbs have been tested in laboratory animal infections and in in-vitro experiments against artificially cultured adult schistosomes Of some 200 examined, several, including the chrysanthemum, have shown some activity Clinical trials of these drugs are being organised mostly in the treatment of severely complicated cases

Details of Therapy

Courses of antimonial drugs used in the past have had the great drawback of keeping the patient too long from his work Attempts have been made, therefore, to reduce the length of treatment to an effective minimum Clinically and experimentally, intensive therapy, such as that devised by Alves and Blair, has been found very toxic and less effective than longer courses It has been discovered recently, however, that satisfactory results can be achieved by reducing the standard twenty to twenty-five days' course of therapy to a week This technique has resulted in a great saving of time and has proportionately reduced the immobilisation of the working patient to a period he is prepared to accept, thus leading to more efficient therapy and fewer relapses

Some of the dosage regimes which have been examined are detailed in the accompanying table The figures are based on the results of a single experiment carried out in hospitals and clinics and involving over 5000 cases of active *S japonicum* infections The therapeutic agents were potassium or sodium antimony tartrate given intravenously

In the field the therapeutic courses most generally used now are the seven-day and twenty-day regimes Presumably the former will become the standard technique

Results

In the above investigation, stools were examined for *S japonicum* eggs before, during, and after treatment, by hatching and sedimentation methods In some cases rectal biopsy was also performed With successful treatment eggs in the fæces became fewer about a fortnight after commencement of therapy and disappeared during the fourth week Early indications of success were the passing of opaque eggs which would not hatch, or the hatching of miracidia which did not survive beyond a few minutes In the follow-up, groups of three successive stools were examined every three months for a year after treatment

As will be seen from the table, the very short intensive courses were not as effective as the longer lower-dosage regimes Of the cases which relapsed, 70% again passed eggs within three months of treatment and 85% within six months Examination beyond six months revealed only a further 3% The routine follow-up recommended was therefore the examination of three successive stools at three and at six months after treatment, or, as a minimum requirement, at six months " Cure " was defined for practical purposes as being egg-free after twelve months It is realised, of course, that this may not be an adequate definition in some cases but it is believed to cover most

Side-effects of Potassium or Sodium Antimony Tartrate

Immediate toxic effects are often severe and occasional deaths occur.

In the one-day and three-day intensive courses side-effects were notable. Severe anorexia developed early and nausea and vomiting were common. A short period of dry coughing frequently appeared during the injection of the drug or immediately afterwards.

In the seven-day course, there was often pronounced anorexia and nausea and vomiting which appeared about the third day and persisted until the finish of the treatment. Coughing was usual.

In the longer courses, in which the dosage was built up more slowly, similar toxic effects developed and reached their maximum about the eighth day. Side-effects were less common and less severe in patients under 16 years of age.

Similar immediate toxic effects were prominent with all the other active antimonial compounds tried. Exfoliative dermatitis occurred in a few cases in the later stages of treatment.

Treatment of Complications

Patients in advanced schistosomiasis are treated in general hospitals or regional centres. On admission they receive as a routine a high-protein diet and appropriate vitamins for a week or more while diagnostic procedures are carried out. Cases with obvious hepatic involvement are placed on a low-salt diet.

Certain severe cases, especially in the hepatic group, are selected (at their own request) for treatment with Chinese herbs, some of which cause watery catharsis with considerable relief of œdema and even of ascites. I was told that cases which responded in this way were afterwards given standard antimonial treatment, sometimes successfully. So far as I could ascertain the clinical use of Chinese remedies for schistosomiasis was at present confined to these complicated cases.

Portal hypertension, which develops in chronic or frequently reinfected cases in early adult or middle age, is regarded as the most severe complication.

Although in such patients ascites is common and often severe, paracentesis is rarely practised except for bringing essential immediate relief, since it has been found that the frequent removal of ascitic fluid often establishes a " chronic " state in which regular drainage becomes necessary. Attempts are made, however, to reduce the fluid by salt-free diets and diuretics.

Hepatic coma and mental symptoms are common. Reduction of protein intake sometimes leads to rapid and dramatic improvement in such cases.

Hæmatemesis and melæna are serious hazards, the former arising from rupture of varicosities in the gastric rather than œsophageal veins.

Hepatic disturbances and hypersplenism have been relieved by various surgical techniques. Thus, splenectomy has been found beneficial in many cases, and is usually followed by full courses of antimonials.

Cross-circulation techniques including splenorenal or porta-caval anatomosis and ligature of the hepatic artery have been carried out for the relief of portal hypertension. Some cases have benefited greatly by these procedures and have lived for years after operation. The operative mortality is however still high.

The prognosis of complicated hepatic cases on the whole is poor, whatever is done for the immediate relief of symptoms. Nevertheless, many of the intermediate cases, even those in which severe hæmorrhage has occurred, are temporarily benefited by treatment.

DIAGNOSIS

In early cases the diagnosis depends on the discovery of the ova of *S. japonicum* in the fæces or in scrapings or biopsy specimens taken during proctoscopy.

Eggs in fæces.—The ova are revealed by examination of stool smears, by stool sedimentation methods or by the hatching technique in which a sample of fæces is allowed to come into contact with water so that miracidia hatch out. Comparative studies of these methods carried out on a very large scale have shown that the direct examination of the stool is the least, and the hatching technique the most, reliable. Thus, in one study involving over 5000 patients, a single examination of the stool by the hatching technique disclosed 1500 more positives than the sedimentation technique.

Examination of successive stools also increases the overall chance of finding eggs. For instance, in a group of 980 cases in which ten consecutive stools were examined, 480 were found positive at the first examination and 750 by the seventh. Thereafter further examinations revealed very few more positives.

Rectal biopsy.—All clinicians seem agreed that the examination of rectal biopsy material considerably increases the chance of positive diagnosis even when there are no obvious lesions. To facilitate immediate control of accidental hæmorrhage following biopsy, specimens are taken from tissue not more than 6 in. in from the anus.

Antigens similar to those used for intradermal tests are used to determine the presence of complement-fixing bodies in the sera of early cases, late cases, and cases at various periods after successful treatment.

With suitable antigens (including the " liver-ova " antigen referred to below) positive reactions are obtained in the majority of active infections (85–90%), and in a smaller proportion of treated cases. False positives are rare, even in cases in which other trematode infections were present. The test has some prognostic significance. For instance, in a series of examinations using adult worm protein-fraction as antigen, positive reactions were obtained in 15 out of 15 cases tested three months after treatment, in 7 out of 9 six months afterwards, in 5 out of 11 up to two years afterwards, and in 2 out of 7 cases examined two to four years afterwards.

Other successful serological tests which are being studied, especially in experimental animal schistosomiasis, include precipitin reactions and cercarial (C.H.R.) and miracidial fixation. The latter are said to be in some respects more sensitive than complement deviation but are not in general diagnostic use.

Diagnosis in Mass Surveys

Direct stool smear examination, sedimentation, concentration and hatching, rectal biopsy, and serological methods are all unsuitable for large-scale surveys. In the last few years therefore much attention has been directed to the study of intradermal antibody-antigen reactions in all stages of the infection before and after treatment. Most extensive research has been carried out by Chung (1956) and others, for instance, on the activity of antigens made from adult worms of either sex, from extracts of polysaccharide and protein fractions of adults, from eggs, miracidia, cercariæ, and from snails. These workers recently prepared from the livers of laboratory-infected rabbits a powerful antigen which has been mass-produced and used in screening the population of something like 60 million believed to be at risk to schistosomiasis.

The Chung antigen is prepared as follows:

> Rabbits are infected with cercariæ, and are killed six to ten weeks later. The livers, which are filled with pseudotubercles containing ova, are homogenised after removal of adult worms, and dried. A 1% saline extract of this material is made up with 1 in 10,000 parts of ethyl mercuric thiosalicylate as a preservative, and can be stored in the cold for several months without loss of activity.

The skin test is carried out by the intradermal injection of 0.1 ml. of antigen diluted to 1 in 1000 or 1 in 2000. The control is an intradermal injection of 0.1 ml. of saline containing the same quantity of preservative. Readings are made about fifteen minutes after the injection. A positive reaction is shown by the appearance of a weal with pseudopodia, surrounded by a zone of erythema The reactions subside after an hour

The diagnostic value of this skin reaction in individual cases is limited by cross-reactions which may arise in infections with other trematodes, notably paragonimus, clonorchis, and fasciola (from the adults of which active antigens may also be made) To some extent this difficulty may be overcome by determining the reactions of the skin to increasing dilutions of the several specific antigens until the point is reached at which the reaction to the schistosome antigen remains positive and that to the others has become negative In mass surveys in areas where the distribution of the other flukes is approximately known, however, a positive specific intradermal reaction to the schistosomal antigen is reasonably considered significant

The results of intradermal reactions to the liver-ova antigen correspond to those of complement-fixation reactions with the same antigen, in that positives occur in a very high proportion of active infections and are progressively fewer after treatment Similar results so far as intradermal reactions to specific antigen are concerned have been reported in *Schistosoma hæmatobium* infections by Sherif (1956) and others, but Oliver-Gonsalez (1954) observed the reverse with a *S mansoni* egg antigen Chung suggests that the Chinese antigen owes some of its activity to the liver tissue from which it is prepared

Methods and Technique of Schistosomiasis Control

FÆCES AND SCHISTOSOMAL EGGS

In the campaign against schistosomiasis emphasis is being laid particularly upon limiting the dissemination of infective eggs by controlling promiscuous defæcation and by storage of fæces for up to a week before use in the fields, in order to allow the ammonia generated to destroy the ova, which might otherwise survive for several months The cooperation of the people has been sought by propaganda expounding the social and sanitary advantages of fæcal control and by official payment for night-soil, pro rata, according to age (? on a basis of weight for weight)

In most villages and cooperatives today, each family has its own collecting-pots which are emptied daily into common earthenware tanks in the village compound The communal pots are sealed when full and the contents are removed after the requisite time and transferred to open tanks in the fields for immediate use The collection of fæces in this way, together with subsequent properly supervised washing of individual family and community vessels, avoids one of the principal dangers of the past, when washing of night-soil containers in the ditches and canals was a common means of spreading the infection to the local snails

The dissemination of infection by human fæces is being brought under control in this way, but a major problem still needing a solution is the conservation of animal fæces

This is particularly so in domestic animals which have been shown to be a dangerous source of infective eggs, especially cows and the ubiquitous water-buffaloes, which wallow in every irrigation ditch (the main unsavoury homes of the intermediate host) Moreover, some animals, including the coprophagous pigs, easily become infected and pass eggs in the fæces, or are capable, like dogs, of passing viable ova after eating infected material Since the water-buffalo is the most important of all domestic animals, its susceptibility to infection is of primary significance and has to be taken into account in the control of schistosomiasis Medical and veterinary workers are collaborating to find practical means of reducing such animal infection and controlling the dissemination of suspect fæces

CONTROL OF SNAILS AND CERCARIÆ

The prevailing methods used for killing snails are based on the results of years of concentrated research which have been going on in the field and laboratories, such as those of the Shanghai Institute of Parasitology, where the bionomics of oncomelania from all parts of the country have been studied, and their reactions to various physical and chemical environments examined

Infection of Snails

The breeding habits of oncomelania have been carefully watched with a view to finding biological techniques for limiting the snail population in the field It has been found that mating takes place through the year but is at a minimum in the spring and early summer and at a maximum in the early winter Hibernation starts in the autumn Egglaying and hatching also go on throughout the year, but the latter is slowed by cold In the laboratory the adult snail develops in about six months

Snails are most numerous in wet, moist soil near water and thick grass The population is densest in irrigation ditches and becomes progressively thinner along the banks of rivers and canals, in rice-beds, and in the paddy fields Isolated pools of water are less important breeding-grounds The mortality-rate of uninfected snails in the field does not change much with the seasons but that of infected snails increases in the summer and decreases in the early winter The mortality of both is higher in dry conditions

The activity of snails has been studied under many circumstances They are most active at night and crawl at a rate of about 3 metres in a month They are found on land mostly within $1^{1}/_{2}$ metres of the water surface, fluctuations in the level of which appear to make little difference

Naturally infected snails are found throughout the year, the highest infection-rate is in August-September Using cercariæ from rabbit-liver ova, laboratory infection can be achieved in about 60% of many local strains of oncomelania at temperatures of 21 to 36°C, but there is some variability in the susceptibility of snails collected from different districts in the endemic area Cold conditions very considerably reduce the infection-rate Planorbiid and other genera so far examined have not been infected

Anticercarial Measures

Cercarial discharge from snails occurs earlier after infection in a hot environment than in the cold Snails may remain infected and capable of discharging cercariæ for over two and a half years

Cercariæ from captive or naturally infected snails remain infective for up to three days when suspended in water, provided the temperature is low There is no difference in infectivity towards mice amongst cercariæ collected at various times of the year under natural or laboratory conditions

Although human infection most commonly takes place as the result of penetration of cercariæ through skin exposed to the water of canals and irrigation ditches (fig 2), it can also occur through contact with minute droplets Dew-drops in some paddy fields have been found to be charged with active infective cercariæ in very large numbers It is not yet known how significant this path of infection is, but it clearly

Fig 2—Exposure to cercariæ in canal water

has to be considered in attempts to limit the spread of infection, particularly in local areas in which human or animal defæcation has not yet been adequately controlled

The destruction of cercariæ and the prevention of their penetration through the skin have been studied by means of various chemical techniques and the use of protective clothing Under standard experimental conditions in which the shaven bellies of white mice are exposed to water containing known numbers of cercariæ, over a hundred test substances, including native herbs, have been examined by applications to the animal skin of oils, ointments, infusions and solutions Mixtures containing Tung oil have been found effective in protecting mice and have been used in the field in the form of repeated applications to exposed areas of skin Many substances which kill snails have also some antimiracidial and anticercarial effect Such methods may have some temporary value but are regarded only as palliative

Chemical Control of Snails

The toxic action of many substances in the form of solutions, emulsions and powders has been studied, including copper sulphate, paris green, calcium arsenate and arsenite, calcium cyanamide and superphosphate, wintergreen oil, and phenol

Copper sulphate is a good molluscicide in a dilution of 50 parts per million, at which concentration most of the others are ineffective The copper salt is expensive, however, and relatively inactive when mixed with mud or dirty river-water The compounds most commonly used on a big scale are paris green and calcium arsenate (or arsenite) The former is effective but slow as a spray in concentrations of 9 0 g per square metre but is unfortunately harmful to animals and rice crops The latter is freely used as a spray in concentrations of 6 to 12 g per square metre in areas away from livestock or humans

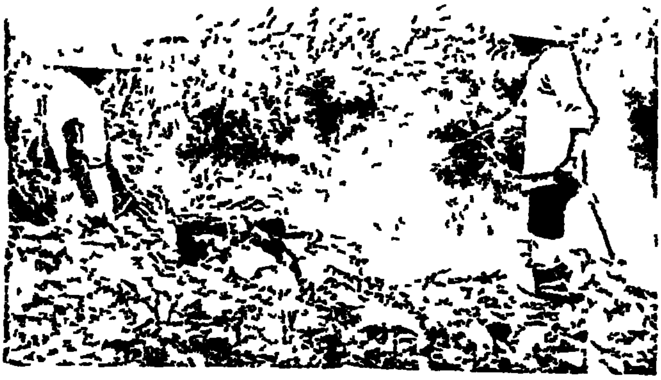

Fig 3—Ditch spraying with calcium arsenate

Synthetics such as dicophane (D D T), gammabenzene hydrochloride dimethylphthallate and sodium pentachlorophenate, and substitute phenols, such as sodium tetrachlorophenate and diethylparanitrophenyl thiophosphate (E 605) have also been examined Of these the latter group are most active molluscicides, but some of them are unfortunately extremely toxic to fish and are ineffective in the cold, their activity is notably reduced by contact with mud or dirty water

Nearly six hundred Chinese herbs have been tested, of which fewer than twenty have any appreciable molluscicidal effect in concentrations of 1% or lower For example, infusions and oil emulsions of croton have been proved successful under laboratory conditions but considerably less so in the field So far no indigenous drug has been found economically satisfactory for use on a large scale

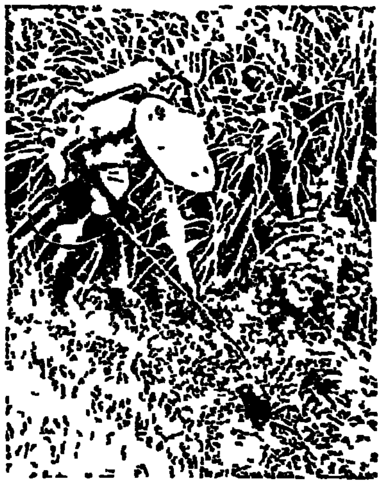

Fig 4—Using a petrol flame-thrower on the banks of ditches

Physical Methods of Killing Snails

During the summer large numbers of snails are found on land within $1^{1}/_{2}$–2 metres from the water line Spraying, burning, and scalding of this area are all effective killing measures and are widely used in villages and other occupied regions The cheaper technique of spraying with poisonous chemicals, such as calcium arsenate, is restricted to the ditches and canals in the fields (fig 3)

The burning of the grass on the banks of small creeks and ditches is carried out by means of portable petrol flame-throwers carried on the shoulders or on wheelbarrows The banks of larger canals and streams are scorched by flame-throwers mounted on punts, and burning carbon monoxide gas made on the spot (figs 4 and 5) This process is slow but effective, as I could see for myself when I joined the hordes of village children picking up roasted snails in the wake of the operators

Snails embedded in mud are not destroyed by burning or spraying and have to be killed by other means, the best of which is some form of ditching

Snails are normally concentrated within 10 cm of the surface of the mud near the water level, if they become buried deeper they suffocate Farmers are therefore encouraged in the winter months to concentrate on the time-honoured better-

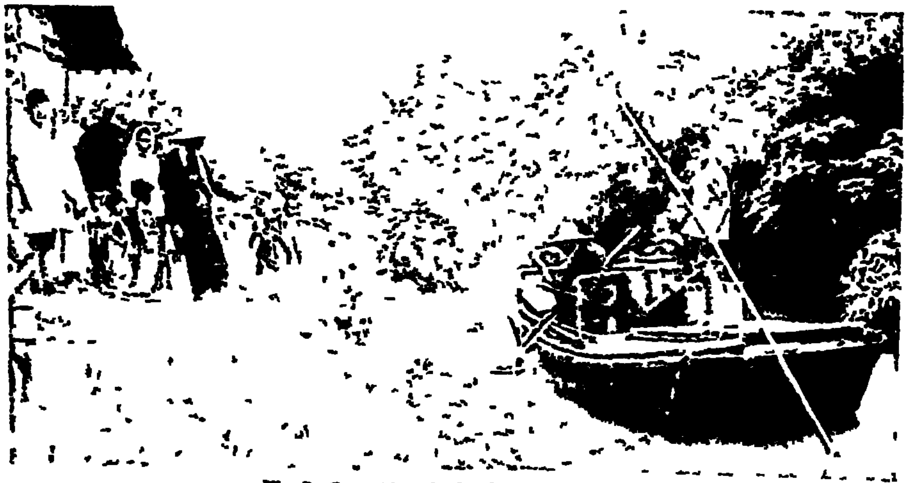

Fig 5—Scorching the banks of a canal

ment of their canals and ditches by manually removing and burying the snail-containing mud In this way the banks of waterways are cleared yearly of weeds and the ditch beds are deepened or replaced A recent field experiment showed that the more thorough process of filling in the old ditches and digging new ones was the most effective and accounted for almost all the snails buried in the mud The simpler process of clearing overhanging grass and covering one side of the ditch with soil from the other is less effective, but removal of the superficial layers of earth from both sides and storage or burial of this material is a highly efficient technique, 70% of the snails dying within a month and 98% in three months

Simple methods of this kind are now being used on a large scale, especially during the winter, after the killing of active snails in the summer by means of burning or spraying The effectiveness of these procedures was demonstrated recently in one experimental area in which the population of snails was reduced by 98% twelve months after treatment (filling in and replacement) of 15 km of ditches

Other physical methods of control which have proved valuable in appropriate areas are reclamation of "low or flood land by the erection of embankments and the subsequent removal of the overgrowing grass", and in some cases the conversion of reclaimed rice fields for the growth of other crops These more extensive operations have been completed by the antischistosomal organisation in collaboration with other departments and Ministries They illustrate the combined operations necessary for the successful outcome of the nation's all-out totalitarian attempt to "liquidate" the threat of schistosomiasis to the future of the new China

The combination of burning and spraying plus ditching is already having a considerable effect on the population numbers of the intermediate host This, together with the mass-treatment campaign which is already in active operation, cannot fail greatly to reduce the endemicity of schistosomiasis within the afflicted areas When suitable methods for the prevention of infection in the domestic-animal reservoirs have been evolved, the disease should be brought swiftly under control

My thanks are due to my many Chinese friends for valuable help and advice

Medicine and the Law

Jury's Responsibility in Assessing Diminished Responsibility

At the trial of a young man on a charge of capital murder by shooting, one of the defences put forward was that he was suffering from diminished responsibility within the meaning of section 2(1) of the Homicide Act, 1957 Although there was evidence which could have justified the jury in finding that it was a case of diminished responsibility, it was not such as to compel them to come to that finding According to the evidence the man had an intelligence quotient of 110 Copies of section 2(1) were handed to the jury so that they could see it, and the judge, summing up, read the section to them, told them that it was for them to decide whether or not the man was suffering from such an abnormality of mind as substantially to impair his mental responsibility, and then reviewed the evidence on that issue The jury convicted the man, who was sentenced to death On his appeal it was argued for him that the judge should have given the jury a direction as to the meaning of the expressions "abnormality of mind" and "mental responsibility" in the section, and that, since counsel for the prosecution in his speech to the jury had submitted that "abnormality of mind" was limited to a deficiency of intelligence and that certain conditions of which evidence had been given—emotional instability, temperamental instability, psychopathic personality, gross personality disorder, immature personality, and abnormality of control of the emotions—could not come within the expression, the judge should have ruled upon those submissions For the convicted man it was contended that "abnormality of mind" was not equated with deficiency of intelligence but that a person suffering from those conditions and unable to control his emotions came within the section

The LORD CHIEF JUSTICE, giving the judgment of the court, said that a judge could do no more than call the attention of the jury to the exact terms of the section which Parliament had enacted and leave them to say whether upon the evidence they found that the case came within the section or not

When Parliament had defined a particular state of things, as they had defined what was to amount to diminished responsibility, it was not for judges to attempt to define or redefine the definition It was a question of fact in any particular case for the jury to decide The conception of diminished responsibility was borrowed from the Scottish common law which recognised that a man might be not quite insane but a borderline case and that that was the sort of thing which amounted to diminished responsibility Where a defence of insanity was set up it had always been for the jury to find whether or not there was a disease of the mind and that could only be found by listening to the medical evidence and the facts of the case and coming to the conclusion whether what the defendant did was the act of a sane or an insane man So here all that could be done was to read the section to the jury and say "these are the tests which Parliament has said are to be applied You are to consider whether the defendant has abnormality of mind"—and his Lordship did not know how that was to be defined because it was very difficult to say what was a normal person—"whether arising from a condition of arrested or retarded development of mind or any inherent cause or induced by disease or injury If you find any of those matters in the evidence, you may find a verdict of manslaughter and not of murder"

In English law the expression "What would be the act of a reasonable man?" was very common, but his Lordship did not know of any definition of a reasonable man, The jury had to decide for themselves whether the action in question was the action of what they would call a reasonable man and so here the matter was entirely one for the jury The judge had put the case in the only way it could be put and it was not his duty to enter into metaphysical and philosophical distinctions between intellect and emotion The appeal was dismissed

In England Now

A Running Commentary by Peripatetic Correspondents

ALTHOUGH we always say what we mean, we do not invariably mean all that we say, but on this occasion it is with no negative reservations that we welcome the appearance of a new journal, the *Journal of Negative Results* (*J neg Res*), and hail it with the freshly minted phrase that it "fulfils a long-felt need" Indeed, so much material is awaiting publication in this field that the editorial board have adopted a strict policy, for the time being, papers are only accepted if statistical analysis of the results gives $P > 0 9$ Later, the editors hope to be able to include papers whose results are statistically significant, but are otherwise meaningless

For the opening number the editors have secured a distinguished panel of contributors, but diffidence in face of the laws of libel forbids us to mention their names The papers include an interesting historical article on Medicine in Laputa, and there is an essay on the negation of negation The journal has the distinguished format which we have come to expect from the Erewhon University Press, but we hope that in future issues the blank cover will be replaced by something more misleading The motto of the new journal is taken from Faust—"Ich bin der Geist, der stets verneint" We wish the editors well in their new venture, and hope to assist them with papers from time to time

* * *

We had known for some time that the Royal Ontario Museum in Toronto was putting on one of the largest exhibitions of English silver ever assembled and that it was being opened by the Governor General This made the opening a social as well as a cultural highlight, and 1500 of the Best People were invited But, of course, in a population of only 16 million it is not really selective to be one of the 1500, and so 300 of the Very Best People had been asked to dinner before the opening But 300 is such a crowd, so 40 of the Really Very Best People were going to a cocktail party before the dinner before the opening The big problem was how to face my friends on Monday because I had not been invited even to the opening, and some of them might be one, two, or even three up In a flash of genius I got myself admitted on the previous Friday, to the press showing (on the grounds of being a *Lancet* Peripat)

The press show was rather like going to see a film star in his dressing-room, because the display had not yet been completed. There were great hunks of silver lying about all over the place, and knee-deep in candlesticks, mirrors, sauce-boats, and salvers there were policemen with guns They looked a little sheepish, it did seem pedantic to guard the stuff when the museum staff were continually casually mislaying objects worth a hundred thousand dollars Also around the place, among my temporary press colleagues, were the art critics who had been reading that *Penguin* book about silver This gave them the chance to say "surely that's a trifid spoon?" The label confirmed this, but it plunged me into humiliation I did not know that one ate trifids with a spoon. Ah, here is a trifid fork So next time I am offered trifids at a banquet I shall nonchalantly pick up a spoon and fork, and not use a knife—if I can find out in the meantime how to recognise trifids

I found that many of the still open display cases contained notes pencilled on paper to show where the pieces were to go Here is one that says "the good one" That is the height of patronage, it seems to me Here is a solid silver picnic set, of all things, made in 1680, with knife, fork, spoon, condiment box, and nutmeg-grater There are 13th-century spoons with no nonsense about them and rococo work with a lot of nonsense, graceful sauce-boats and curly salt-cellars, the Everest cup and the Coronation cup There is a silver bathtub and an aspidistra pot, both labelled as wine-cisterns

By now I was getting pretty blase about silver and was baffled rather than impressed by a mirror belonging to the Duke of Brunswick This is about as big as a bus, with 3-D coats of arms all over and a couple of silver chairs to match Another pencilled instruction catches my eye. "Put the *art nouveau* thing here" That makes my day "The *art nouveau* thing"—so casual, with a hint of knowing what *art nouveau* is I'm all set for Monday now "Oh, are you going to the opening tonight? I saw the show last week—you really must look out for a rather nice *art nouveau* thing they have there "

* * *

My two-year-old was lying in his bath and probably for the first time his eye fell on his umbilicus There was a horrified expression in his eye and he called out, "Mummy, Mummy! Look! Hole! Mend!"

* * *

The lumbago-sciatic shooting now being open[1] we can look forward to some smart exchanges, for the subject has long been controversial Even in Shakespeare's time the widest extremes of view were evidently held The remark of the 1st Gent to Bawd "How now! Which of your hips has the most profound sciatica?" (*Measure for Measure*) shows the ribald back-slapping approach as opposed to Sycorax's serious and intensive treatment of Ariel by twelve years manipulation in a cloven pine without anaesthetic (*Tempest*) Rigorous though this regime may have been, it undoubtedly restored the patient the full use of his exceptional mobility

THEBES

It was evening when we reached the village,
After the long drive over hot, dusty plains
There, still sharing some needs with ancient wayfarers,
We stopped for bread and water,
So learned by accident, believing it many miles distant,
That this was Thebes

Could this be Thebes, a city of kings?
We might have known, out on the plain
Where corn ripened and the kites and vultures scavenged
And pitiless heat beat down,
That there was the inevitable setting
For Antigone Almost we passed her,
Still pitifully scraping a grave for her dead brother
Out there nothing has changed
But here in the streets, who remembers doomed Œdipus?
Who has even heard of successful Creon?
Yet this was, this is Thebes
Here now, here ever,
Left by the long since ebbing tide of history and myth and drama,
The grey-haired elders, the perennial chorus,
Sit sipping their drinks, savouring the flavour of life and commenting on it
At small tin tables on the shady side of the street

There are locked, rusty gates nearby (the elders will direct a pilgrim)
Where carved, broken stones,
Mortal relics of an immortal past,
Lie in a sleepy garden
Petunias and hollyhocks and flowering trees
Wave them a careless tribute of royal colours
Heroes and lovers, human or sired by gods or dreamed by poets,
Sleep alike their long sleep
While hawks and doves nest neighbouring among crumbling masonry
To this garden we came, rare visitors
The custodian, shrunken, wrinkled, brown,
Unordained priest of a self-consecrated shrine,
Welcomed us, stroked a stone lion for us,
Intoned the names of the muses, spelt out caressingly
A little tombstone of much loved Demetrius
He gave us each on parting a rose and a sprig of mint,
But these we lost, and now have nothing left of Thebes
Except the ghost of a perfume and a memory

Letters to the Editor

THE "LADDER"

SIR,—In giving evidence before the Royal Commission last week I wanted to put in a word for senior registrars who by their energy and intelligence had climbed the ladder at their medical schools, only to find too often that it led nowhere

Let me explain what I mean by this ladder The ambitious boy who enters a medical school singles himself out by winning prizes in the annual class examinations, and later by obtaining honours or perhaps a gold medal in university examinations After qualifying he must compete for a series of posts, and all the time the competition grows fiercer Indeed he may be eliminated before he is ready to take the last hurdle, that of senior registrar, because he has failed in the examinations for the higher degrees In this manner, from the survivors of this cut-throat struggle, the hospital staff is elected And the young consultant so chosen is now singularly efficient, not only on account of the severity of the competition but also because he has gone through a period of intensive training, which often extends, according to the Royal College of Physicians, over a period of ten, fifteen, or even twenty years after qualifying In this way he has accumulated a store of knowledge and experience which gives him a great pull over those who have not had the advantage of this discipline

But will this last? Material rewards are of course not the only incentive, but in the past the incomes enjoyed by men who were successful in consulting practice led students at the top of their year to attempt to climb this ladder But these inducements have been whittled away and if these men can no longer look forward to an adequate reward for their labours, they may plan their lives differently They know that now they will have to face long years of training after they have qualified, years of comparative penury, years of uncertainty, because in the end success is far from assured And they know too that in the event of failure no alternative career in general practice may then be open to them at their age The waiting years have been unduly drawn out, and the disparity between the number of consultant vacancies and the number of senior registrars competing for them is such that men are beginning to ask "Is the game worth the candle?" Already there has been a sharp fall, both in London and in the Provinces, in the number of applicants for the post of registrar The writing is on the wall for those who can read

I had hoped that if I could describe accurately the means used by hospitals to sift candidates for election to their staffs I might be able to convince the members of the Royal Commission that the senior registrar who had emerged successfully from this ordeal ought not to be thrown lightly on the scrap-heap, that his achievement was worthy of some reward Moreover while I was speaking of the senior registrar I had at the back of my mind the whole question of consultant recruiting Alas I was met only by doubt whether there was in fact any such ladder, that all men in our calling are equal If I had been wise I should have left it there Others in good time would have taken up the task of explaining how the consultant ranks are recruited But in the quick exchanges that followed I allowed myself to be drawn outside my argument I was asked in effect whether I considered the consultant a person apart, and only then did I tumble to the fact that my arguments for rewarding the man when he had climbed the ladder had been taken as critical and even derogatory of those who had never even made the attempt I protested I spoke of the "very high standard" of general practice as I had known it and of the "extreme ability" of many practitioners in my own experience But the damage was done

I was dean of a medical school throughout the twenty-five years I was on the hospital staff, with the exception of a few months in 1920, and it was my custom to spend about three-quarters of my day among my students I was completely engrossed in them as individuals, in their plans for the future, in their hopes and fears And I like to think that there existed between us mutual respect and even affection, certainly on my part there has been an enduring regard for their solid worth and good sense The overwhelming majority became general practitioners and I should be sorry if any of them were led to believe by the enterprise of the Press that I have changed and admire no longer the fine job they have made of their lives of service

London, W 1 MORAN

DEATH FROM POSTMATURITY OR INDUCTION OF LABOUR?

SIR,—Mr Gibberd (Jan 11) rightly points out that present methods of inducing labour are not entirely free from danger However, experience does not support his suggestion that the dangers of induction outweigh those of postmaturity in uncomplicated cases In a group where the dangers of postmaturity are relatively great (primigravidæ aged 25 or over) we adopted in 1953 a policy of routine induction in the 42nd week and began to use cæsarean section more freely, particularly if there are signs of fœtal distress, especially meconium in the liquor amnii This policy has been very successful in producing a marked reduction of perinatal mortality Dr Elizabeth Turnbull and I have published the relevant data elsewhere[1]

Midwifery Department,
University of Aberdeen DUGALD BAIRD

SIR,—I would like to present figures from the Obstetric Unit, University College Hospital, for comparison with those of Mr Gibberd

From 1952 to 1957 inclusive 386 patients (240 primigravidæ) were induced for postmaturity, mostly close to the 42nd week of gestation There were 20 cæsarean sections There were no deaths in this series attributable to the induction or to anoxia or asphyxia 3 deaths which occurred were

1952 Stillbirth, weight 7 lb 3 oz, 42 weeks Low amniotomy revealed meconium Fœtal distress developed 11 hours later and the fœtus was delivered by cæsarean section but failed to breathe Necropsy showed nutmeg liver, cystic adrenals, and a phæochromocytoma The mother, a primigravida, had rubella in early pregnancy and positive Wassermann and Kahn reactions

1956 Neonatal death Mother primigravida $2^{1}/_{2}$ weeks postmature Induction-delivery interval 98 hours, labour 20 hours Difficult forceps delivery, baby died 3 hours later Bilateral tentorial tear attributed to difficult labour and delivery of postmature fœtus with hard and unmouldable skull

1956 Neonatal death, at 23 hours from pneumonia Induction-delivery interval 68 hours Oxytocin infusion for 42 hours, forceps delivery This patient was not given antibiotic cover after the induction, and the pneumonia from which the fœtus died may have been contracted in utero

---

[1] *Brit med J* 1957, ii, 1021

Factors which make the induction of labour safe for the postmature fœtus would seem to include

1 Routine antibiotic treatment for the mother from the day after induction until delivery [1]

2 Induction by low, in preference to high, amniotomy

3 Not delaying induction beyond the 42nd week

4 The use of oxytocin (not 'Pituitrin') intravenous infusion (not frequent small injections), with a tocodynamometer to assess the uterine response so that the infusion-rate can be suitably adjusted, to supplement or proceed amniotomy in all patients for whom the oxytocin-sensitivity test indicates that the uterus is insufficiently irritable to respond to amniotomy alone

5 Giving attention to early signs of fœtal distress and not allowing the labour or induction to be prolonged if there is meconium or abnormal slowing of the foetal heart-rate This entails 4-hourly observations on the fœtal heart—$^1/_2$-hourly if the maternal blood-pressure is raised, and $^1/_4$-hourly during oxytocin-infusion treatment [2]

These figures show that induction can be a safe and life-saving procedure by avoiding excessive postmaturity It can save more lives than Mr Gibberd gives even the perfect method credit for This may be because these babies have an average weight in the 8 lb region and good ability to survive provided they are saved from prolonged anoxia and the dangers of a difficult delivery In his opening sentence Mr Gibberd postulates anoxia as the basis of fœtal death in postmaturity Is it not possible that size and rigidity of the head could increase the danger of delivery too?

University College Hospital,
London, W C 1

C N Smyth

Sir,—Mr Gibberd's paper advances our knowledge regarding the management of postmaturity In trying to gain a familiarity with the problem I examined some 11,000 consecutive case-records I found that the stillbirth-rate rose steadily from 1 47% in patients delivered at the 40th week, to 9 3% when pregnancy had lasted 44 weeks or more In this latter group asphyxia was a *possible* cause of almost 80% of the stillbirths In half of these cases, however, death did not take place until labour had lasted more than 48 hours, and it may be argued that prolonged labour rather than postmaturity per se was the cause of the asphyxia, and further that the cause of death in some of these may well have been intrauterine infection of the foetus and not asphyxia at all

By a less lucid reasoning than that of Mr Gibberd I arrived at a similar answer—namely, that wholesale surgical induction of labour could not be expected to solve the problem I feel, however, that greater emphasis might be placed on the point that it is in the very group of patients we are trying to treat that induction is most likely to be unsatisfactory and dangerous

If, for example, we knew at the 41st week that, in the absence of interference, labour in a particular case would not begin for another 3 weeks, and if we made some attempt to explain why this should be so, we might suggest a mechanical reason such as malpresentation or disproportion, or we might say the cause was humoral in nature, or we might simply say that the uterus was not yet ready for action In any case we might hesitate before rupturing the membranes since in such a patient we would not be surprised to find that labour was delayed in onset and inert in character There is a considerably increased incidence of prolonged labour in postmature cases, and I believe the relationship to be one of common cause rather than of cause and effect The common cause may be mechanical or it may be humoral

When, to this contention, is added the consideration that it is not possible to preselect these cases, so that the operation must be performed unnecessarily in hundreds of others, the argument against induction of labour seems to be a strong one

Cæsarean section may well be the key to the problem, and if we could find a means of detecting the diminishing oxygen reserve of the fœtus before the onset of actual asphyxia, its value would be immeasurably the greater in that it would then be neither too often employed nor too long withheld

Nottingham

J M Gate

Sir,—I was interested in Mr Gibberd's article Is it not fairer to say, however, that the choice is not quite so clear as his title suggests? Most infants that are lost from postmaturity are lost, if the mother is not induced, by anoxia, and die, as Mr Gibberd points out, before, during, or immediately after labour But if the mother is induced, although induction is a hazard, the cause of death is still anoxia in most cases So the real choice is between death from postmaturity and death from postmaturity plus induction, the induction being a factor but not, necessarily, the main hazard

In our department we have practised surgical induction as a fairly rigid routine when the pregnancy has gone 14 days past the expected date as far as we can possibly judge During the past five years (1952-56) 607 consecutive surgical inductions have thus been done where the indication was simply term plus 14 and no other possible factor requiring induction was present Our total fœtal loss, both of stillbirths and neonatal deaths, was 15, but 4 of these had congenital abnormalities incompatible with life So there was a loss of 11 babies—or 1 8% All 11 (compare Mr Gibberd's table II) died from anoxia

Now, granting that surgical induction played some part, I nevertheless disagree emphatically with Mr Gibberd when he says that in uncomplicated cases it is, possibly, better to avoid the treatment of postmaturity altogether, rather than to embark on a rigid policy of prevention Can a loss of 1 8% over a large number of patients be lowered by those who never do a surgical induction for uncomplicated postmaturity? Mr Gibberd's figures (table I) show that at 43 weeks the infant loss is 2 8% and at 44 weeks 4 3% Why should it be assumed that these 11 babies would not have perished from anoxia if allowed to go on and on in utero until the natural onset of labour? We realise that even some of these 11 that we lost might have been saved by earlier intervention with a section, which is now our practice, according to the merits of the case, at the onset of meconium or the finding of scanty or absent liquor, both of which findings are hidden from those who have not ruptured the membranes

Marston Green,
Warwickshire

G S Lester

INFLUENZAL ENCEPHALITIS

Sir,—Dr Dubowitz's account (Jan 18) of two cases of infective encephalitis recalls a case in my practice

On Sept 20, 1957, a boy, aged 13, fell ill with aching, shivering, headache, and stuffiness of the nose He had no cough or pyrexia By Sept 26, deafness, due to eustachian catarrh, had developed, but there was no evident otitis media While his siblings and mother were in bed with influenzal symptoms and his grandmother delirious from influenzal bronchopneumonia, he became severely ill with shivering, sore throat, weakness of the legs, delirium, headache, vomiting, and cough At no time did I find any signs in his lungs His temperature was 104 F, face and eyes were bright red, and meningism was present (stiff neck and straight leg raising only to 30°) His temperature was normal, but he felt as though he was rotating, and as though iron bars were lying on his legs He had obvious nystagmus to both sides and past-pointing to the right No cranial nerves were affected Supinator- and triceps-jerks were not obtainable Biceps-jerks and knee-jerks were present and, on reinforcement, ankle-jerks On Oct 6 meningism was still present, on Oct 8 the tongue deviated well to the right, and on Oct 10 the palate deviated to the left

[3] Karn, M N, Penrose L S *Ann Eugen, Lond* 1951, 16, 147

I last saw him on Oct 14 when he was almost well, but still showed nystagmus He was treated symptomatically throughout

Though pathological tests were not made in this family, the general pattern was similar to that in other simultaneous cases in which influenza virus A was found on cultivation and by complement-fixation tests

Ilford, Essex R N COMPTON SMITH

RADIATION HAZARDS IN PELVIMETRY

SIR,—Dr Lindsay's[1] letter comes as a timely reminder that radiation hazards need not outweigh the advantages of cephalopelvimetry, provided that due precautions are taken, and his ingenuity in screening appears to be a worthy safeguard

From an historical standpoint he might have given credit to Chassar Moir[2] (in addition to Blair-Hartley[3]) for emphasising the dangers of the "brim view" in 1956 Indeed, the former should also have special mention for being 10 years ahead of his time in this regard by observing in 1946[4]

> "There is another objection to the use of the standard method (Brim view) the fœtal part occupying the uterine fundus—normally the breech—receives excessively heavy exposure and one which, for all we know, may be harmful to the fœtus"

In congratulating Dr Lindsay I wish that his ingenuity could remedy two further hazards of cephalopelvimetry—namely, reliance upon radiological predictions of the outcome of labour, and the accoucheur who is unable to rely upon his radiological interpretations of cephalopelvimetry

Department of Gynæcology and Obstetrics,
University of Natal, Durban DERK CRICHTON

TOBACCO-SMOKING

SIR,—You clearly disagree (Jan 4, p 32) with my use of intimidation in curing smoking (though you admit that it may be successful) and you regard persuasion as the only permissible psychotherapeutic instrument

I have often presented the case against the smoking of tobacco persuasively and smokers have expressed their agreement about the utter undesirability of smoking in such terms as "I couldn't agree with you more" Yet not long afterwards they have almost invariably lit up! My long experience of curing smoking in fact suggests that in a high proportion of cases persuasion and reason are not enough, because, where his drug is concerned, the addict is not, as a rule, reasonable It is usually necessary to "get at him" emotionally as well as convince him rationally Fear is the great protective emotion and should surely be utilised to protect the individual from lung cancer and other complications of smoking Is it right to withold any highly effective psychotherapeutic agent in the intractible and still increasing disease, tobacco-smoking? Some smokers may resent its use, but some smokers even resent the putting up of non-smoking notices on a minority of railway compartments, judging by the way these are frequently mutilated

My problem is usually one of scaring smokers enough to cure them I scrupulously avoid overstatement except provocatively, when I try to make this obvious Over the past 8 years the public has been given a sporadic series of "inoculations" with inadequate doses of lung-cancer scare The result is that most smokers have acquired such a degree of immunity that they are almost unscareable

SYRINGES CLEAN OR STERILE?

SIR,—Dr Jackson (Jan 18) deserves warm approval for having taken so much thought and trouble about his syringes His hospital also is to be congratulated on its willingness to cooperate with a general practitioner in his attempt to use only sterile syringes in his practice However, when Dr Jackson says that his syringes inside screw-capped metal containers are "autoclaved for me at my local hospital" I hope that he does not mean this literally Syringes in such containers will not be sterilised by autoclaving but only by baking them in a hot-air oven

Department of Bacteriology,
University of Glasgow J W HOWIE

SIR,—The problem of syringe sterilisation in general practice is a difficult one, and there is no doubt that unsterile syringes are frequently used In spite of this, accidents are relatively uncommon

The method of sterilisation mentioned by Dr Jackson in which the syringe is assembled, placed in a screw-capped metal container, and autoclaved, is not really satisfactory The steam may not penetrate into the container and certainly does not reach the plunger of the syringe, the heat is not acting for long enough to penetrate the container and the syringe-barrel, and the plunger is almost certainly not sterilised

Syringes should be sterilised in a hot-air oven in which they are kept at 160° C for 1 hour Alternatively they can be sterilised by infra-red rays, as recently described by Darmady et al[1]

Cuckfield Hospital,
Haywards Heath, Sussex R W P JOHNSON

LONG-TERM TREATMENT WITH ADRENOCORTICAL HORMONES

SIR,—The interesting paper by Dr Davis and Dr Popert in your issue of Jan 4, emphasises the dangers of reducing or stopping cortisone therapy prior to operation Although cortisone and its analogues have been in general use in this country for some years there is still, in the minds of many physicians, practitioners, and surgeons, an insufficient appreciation of the drastic effects which may follow such reduction or cessation Patients who have been on steroid therapy for more than a few days may suffer acute exacerbation of their pre-existing condition when it is stopped and to this may be added symptoms suggestive of adrenocortical exhaustion For some time we have told patients of this danger and warned them against stopping therapy without instructions

Patients on insulin for diabetes mellitus have known for many years the dangers of stopping their treatment in the face of infection or gastrointestinal attacks Nevertheless, they still do so occasionally under the impression that if they are taking no food, no insulin is required, and these are the cases one still sees sent to hospital in diabetic coma or precoma

The rheumatoid arthritic when he experiences an acute gastrointestinal attack also tends to discontinue all treatment until his nausea and vomiting stops and it is again in these cases that we see the cortisone withdrawal syndrome in its most flamboyant form.

---

[1] Darmady, E M, Hughes K E A, Tuke, W J *J clin Path* 1957, 10, 291 See *Lancet*, 1957, ii, 1155

In our unit we give written instructions to patients and send a copy to their practitioners emphasising that steroid therapy must not be interrupted and that if the patient cannot take his tablets by mouth during an episode of acute gastric enteritis, cortisone must be given intramuscularly. Should an operation be necessary, dosage of cortisone must be stepped up before, during, and after the operation, for surgical operations are a form of stress and all forms of stress call for increased dosage. We have recently seen cases of peripheral neuritis developing after suddenly stopping steroid therapy and several severe and even fatal cases of withdrawal syndrome are on record as quoted by Dr Davis and Dr Popert.

All this has been well described and emphasised for some years but the fact remains that these points are perhaps not sufficiently widely appreciated even today, and Dr Davis and Dr Popert's article is, therefore, both timely and important.

London, S.W.1 F. DUDLEY HART

MEDICAL PRACTICE IN A CHANGING SOCIETY

SIR,—It is with dismay and despair I read Sir Francis Fraser pontificating in his article in your issue of Jan. 18.

Of course, we would like to have a secretary and a receptionist to do our non-medical work. Of course, we would prefer to improve our standard of care by spending more time on fewer patients. How is this to be done when we are paid seventeen shillings and sixpence a year for our five or six items of service, working out at half a crown or three shillings a time? A plumber who came on a Sunday a few weeks ago, to unblock a drain demanded a pound before starting work—a not unreasonable fee—but let Sir Francis realise, we are valued by the State at no more than one-eighth the worth of a plumber.

It makes us smart to be told that we must try and do better medicine, when we cannot produce a higher standard of care unless we are adequately paid to do so. We have to pay our rent and our children's school fees. The Government has appointed a Royal Commission, and our two-year-old pay claim—the first since 1951—has been ignored. The heartbreaking delay has been perpetuated, and there seems little likelihood of any pay increase and implementation of Sir Francis Fraser's pious suggestions for a decade or more.

London, W.2. P. F. KENNISH

REGULATION OF BODY TEMPERATURE

SIR,—I was interested to learn from the recent contribution of Sir George Pickering (Jan. 4 and 11) that the relatively high temperature of the rectum suggests that it may be a source of heat production by bacterial metabolism in fæces. Some evidence of heat generated from this source has been found in the temperate species of tortoises which are at present being studied.

With low environmental temperatures torpidity is induced which results in hibernation and it is not of uncommon occurrence that specimens with any considerable amount of fæces in the upper part of their rectum will after several weeks of hibernation awaken although the environmental temperature is below that permitting comfortable voluntary activity. On the other hand, specimens which have a comparatively empty rectum do not usually awaken. Presumably the bacterial metabolism which is thermogenic raises the body temperature of small individuals to that required for voluntary activities. We find that with adult specimens with a loaded rectum there is seldom awakening from hibernation, as probably it is a greater task to warm a larger body by this source. This latter observation suggests that awakening from hibernation is not a result of any perineal sensation which induces defæcation.

Unfortunately it has not as yet been possible to record the amount of heat evolved by the fæces while within the body, but it appears that a juvenile specimen hibernating with a loaded rectum will, in a period of between four and seven weeks, at an external environmental temperature of 11°C, have an anal canal temperature 4°C above that of a specimen with an empty rectum. This and related problems are to be investigated.

The rapidly changing immediate environmental conditions within the rectum of any animal, including man, will unfortunately never give a reliable temperature reading for any given period. The belief of Mead and Bonmarito[1] is that the temperature of any region depends on the metabolic activity of the region, the temperature and amount of blood flowing through the region and the gradients of temperature to surrounding regions will never allow the rectal temperature to be as precise as some have in the past thought. This would apply to all parts of the body for there is no organ, tissues, or cells which have the same metabolic activity all the time.

Zoological Society of London,
London, N.W.1 TIMOTHY J. HUNT

SIR,—I read with great interest Sir George Pickering's excellent and thought-provoking articles.

He mentions that "the considerable interval between the entry of endogenous pyrogen into the blood-stream and the onset of fever suggests the formation of a further intermediate substance." "Considerable interval" is rather vague and I wonder what the actual figures were. It is often observed that patients have rigors soon after starting intravenous fluids, in spite of adequate aseptic precautions; this is in all probability an unknown pyrogen reaction. My limited observations of treatment with intravenous T.A.B. vaccine, in gradually increasing doses, suggest that rigors almost always start in 15-30 minutes or not at all. Is this a considerable interval for the formation of an intermediate substance?

Victoria Hospital,
Accrington. S. S. JHAVERI

INFANTILE GASTROENTERITIS

SIR,—Dr. Librach (Jan. 11) appears to have missed the point of our article (Dec. 14). Infantile gastroenteritis due to *Escherichia coli* is a specific disease with known high infectivity. Careful bacteriological examination of the stools to exclude the known pathogenic serotypes of *Esch. coli* in a case of infantile diarrhœa and vomiting is essential before one is entitled to consider the ill-defined field of infantile digestive disorders. Our experience suggests that many cases which on clinical grounds appear to be of the non-infective type actually prove to be mild cases of infective gastroenteritis.

Mild cases of infantile gastroenteritis due to *Esch. coli* treated at home often do well without any antibiotics at all. In hospital the problem is somewhat different and the need for treatment of proved cases falls into three categories:

(*a*) Where the clinical condition warrants it (all severe cases and many of the intermediate group). In severe cases we consider that antibiotic therapy should be started as soon as a stool sample has been obtained, and before the results are available.

(b) Those cases from institutions and nurseries where negative stools are required before discharge.

(*c*) Mild cases from their own homes in order to reduce the chance of cross-infection. It is in this last category that opinions may vary.

Treatment on these lines is surely not "indiscriminate antibiotic therapy."

---

[1] Mead, J., Bonmarito, C. L. *J. appl. Physiol.* 1949, 2, 97.

We were surprised that Professor Watkins (Dec 21) is "not impressed with the therapeutic effectiveness of antibiotics", but perhaps he was referring to all grades of severity In severe cases the ease of treatment and the rapid recovery bear no comparison with the difficulties encountered before the advent of antibiotics

Infantile gastroenteritis should be treated on the knowledge of the bacteriological facts and not on clinical impressions It would avoid confusion if this term was used only in those cases in which known serotypes of *Esch coli* were isolated

Hither Green Hospital,
London, S E 13

E H BROWN
E H BAILEY

A FUNCTIONAL NECESSITY

SIR,—Mr Murley's letter in your last issue seems more concerned with attacking the Regional Board and its officers than attempting to deal with the extremely difficult problem of medical staffing in the hospitals As he quotes from correspondence with the Board, your readers will be interested to see, in full, the request which he made for information to be supplied to the Medical Committee This was

1 The numbers of consultants and SHMOs in the various specialties at present working in the region

2 The number of requests for additional consultant staff received from hospital management and/or medical advisory committees since 1948

3 The number of such requests which the Board has been (*a*) able to fill, or (*b*) unable to advertise

4 The number of additional consultant appointments made by the Board without specific request from the periphery

5 The number of requests for additional consultant appointments or additional sessions, emanating from management committees or medical advisory committees which the Board has not agreed to

6 The number of requests for additional consultant appointments, &c, which the Board has not been able to advertise owing to financial stringency (It being presumed that the Board would like to have made these appointments had the money been available)

7 The number of SHMOs who are performing consultant work

8 The number of senior registrars who are "time expired" and seeking consultant appointments

9 Finally, may the medical committee please be supplied with details of any investigations of the medical needs of the region which have been undertaken by representatives of the Board, the Ministry or any other group which has looked into this matter

Mr Murley quotes only an extract from the written reply The reply forwarded to him in fact reads as follows

> "The information requested by him would be most difficult to assemble and would involve a close examination of all the Board's records on medical staffing since 1948—this in itself would be a major undertaking It would then be necessary to analyse them in some detail and the result would still not be satisfactory since in many cases, it would be a matter of opinion as to the net effect of a particular line of action by the Board
>
> "Quite apart from this, the Board's staff is so sorely pressed at the present time, that to embark on this project for Mr Murley would be quite impossible"

This difficult question of the most appropriate medical staffing of the hospitals has been concerning the medical staffing subcommittee of the Board's Establishment Committee for a considerable period of time This subcommittee consists of six members, five of whom are medical

On Oct 16, 1957, the Board sent a deputation to the Ministry of Health asking that most urgent consideration should be given to a number of problems affecting medical staffing, particularly one arising out of the present difficulty over senior registrars, and suggesting a number of solutions The fact that the Ministry of Health have not so far been able to meet the Board in the suggestions which it made, is perhaps due to the intractable nature of the problem as between the Ministry of Health and the profession as a whole

COTTESLOE
Chairman

MANIPULATION FOR BACKACHE

SIR,—Mr Bremner (Jan 4) defines lumbosacral strain as a chronic localised disc degeneration with associated derangement of the corresponding posterior joints and ligaments from which pain presumably arises, in the early stages it is a subluxation or instability of the posterior joints with associated ligamentous strain and in later stages a true osteoarthritis (Nerve-root involvement and general spondylosis are excluded) The long-term management is arranged as follows

(1) If seriously disabling spinal fusion

(2) *If not seriously disabling*

- (*a*) Reassurance and advice on how "to live with their back", if intelligent
- (*b*) Manipulation for the average hospital patient because he expects something more "positive" than reassurance and advice, and if not given manipulation he will seek it elsewhere

The reasons given for manipulation under (*2b*) have no foundation in pathology and could equally well be put forward as arguments for treating with strapping, plaster, corset, local anæsthetic, cortisone, or even an X-ray! As "a priori" arguments for manipulation, they have no value In addition there is nothing in Mr Bremner's concept of the pathology to justify manipulation If manipulation is to have any objective value as distinct from psychological it must mean either a purposeful and enduring correction of a derangement or the restoration of all or part of a range of movement lost through adhesions It would seem that Mr Bremner realises all this and he attempts to justify the use of manipulation on the purely empirical grounds that it produces "satisfied customers" without having any scientific explanation for this

Given the pathology as described by Mr Bremner I cannot understand how 25 of his 250 cases obtained dramatic relief from (presumably) a single manipulation (unless the result was due to the subsequent physiotherapy) I find it much easier to understand why 61 of his patients found relief only in a lumbosacral corset

I make these observations not in criticism of Mr Bremner's article, since he is assiduously careful to avoid making any claim to diagnose with scientific evidence any derangement of the lumbosacral region which he would profess to be able to purposefully correct by a specially designed manipulative procedure My disagreement is rather with those who advocate a practice which implies such a claim Of this school of thought I would ask

(1) What precisely in anatomical terms do you attempt when you manipulate? It seems to be more generally the hypothesis that there is a derangement rather than adhesions

(2) How do you achieve a precise correction of a unit of the intricate lumbosacral complex by a manœuvre exercised on the exterior of the trunk? I can diagnose with X rays a dislocation of the fifth cervical vertebra on the sixth cervical vertebra and reduce it by a manœuvre based on a knowledge of the method of production of the derangement and check my result by X-ray examination, but I cannot practise in this manner on hypothetical derangements of the lumbosacral-joint complex for which I have no objective evidence

(3) Is it right that throughout the country practitioners should manipulate "slipped discs" if many of them have no personal experience of the nature of a protrusion of the nucleus pulposus as seen at operation? Of some hundreds of disc protrusions I have seen at operation I have never seen one that could be reduced by manipulation Perhaps it is only the

irreversible discs that come to operation What evidence is there for disc protrusions reversible by manipulation? I know of no acceptable scientific evidence for this

War Memorial Hospital,
Scunthorpe
DAVID F THOMAS

SIR,—Mr Bremner is to be congratulated on the successful disposal of a high proportion of chronic-backache patients by manipulation May I, as a general practitioner, who has to live with the "patient who has to live with his back" comment on some aspects of his report

(1) The sole criterion used in this series is the patient's subjective complaint about his back, both before and after treatment There is no indication that information about the person complaining of his back would be of any use here this is the exact antithesis to the modern ideal of treating the patient and not the illness Bomford,[1] in his Bradshaw Lecture of 1952, gave an amusing analysis of his own chronic backache which might aptly be re-read by those who deal with "chronic backs"

(2) The results reported are the immediate (one to two weeks) after-effects of the treatment, surely, in chronic conditions the long-term results are of more interest

(3) It is assumed that, as no attempt is made to "sc manipulation", psychological influence as such is excluded This, however, is doubtful Note how Mr Bremner comments "manipulation is the most convincing" to the patient and if not offered this treatment the patient "may well seek it elsewhere" Treatment, therefore, should be "definitive for this "nuisance disease"

I feel confident that psychologists will recognise in thi type of language familiar patterns of powerful unconscious needs in both patient and therapist General practitioners, too will recognise similarities to their own dealings with assorted chronic complainers In short, it is probable that important psychological factors are at work here and can be ignored only at the risk of a loss of clarity in the results It may well be that the diversity of opinions about so pragmatic a treatment as manipulation is due to disregard of psychological factors

(4) This suggests a possible control experiment in the course of such routine work, by omitting the manipulation in every second anæsthetised patient It would be wise, however, to seek the aid of a psychologist in organising such work

London, W 13
A LASK

CANCER OF THE BLADDER IN CHEMICAL WORKERS

SIR,—We were surprised to read a statement, in the Report for 1956 of the Ministry of Health,[2] on bladder cancers of chemical workers, which we think is misleading without fuller explanation We have drawn attention to this and the department of the Ministry of Health concerned agrees that some clarification is desirable

The statement referred to, about cancers, is

> "Some, such as the scrotal cancers of chimney sweeps and mule-spinners, the bladder cancers of chemical workers and the bone cancers of workers with luminous paints have been so far elucidated that, for practical purposes, they have been prevented and eliminated

A statistical survey,[3] published in 1953, has led to changes in industrial practice that may, if they have been well planned, be expected to diminish the hazard in the future The nature of occupational cancer is, however, such that we should expect many cases to occur during the next 20 years in men who were exposed to risk prior to the changes in industrial practice, even if the precautions taken were completely effective, and very few, or no, cases for about 7 years among men exposed to the new conditions if the precautions are not completely effective The effectiveness of the precautions can, in the long run, only be assessed by a further statistical survey made in about 10 years' time

The Association of British Chemical Manufacturers' report[3] used the following terms " there are now solid grounds for thinking that the practical steps already taken and being taken will successfully overcome the hazard The abandonment of beta-naphthylamine manufacture alone should go an appreciable way to achieve this end The introduction of new plant design and operation together with general improvement in factory hygiene should also greatly increase the margin of safety with the other carcinogens" An incomplete appreciation of the situation thus described may have led the Ministry of Health to indulge in optimistic prolepsis

The possibility of the introduction of new bladder carcinogens into the chemical industry (and other industries) must be borne in mind Already xenylamine (4-amino diphenyl) has produced human bladder cancer in the United States[4]

A search of death certificates relating to workers in chemical occupations where bladder tumour is mentioned amongst the recorded causes of death does not show any falling off in the annual number, 17 being found in 1955 and 16 in 1956 The mean annual numbers for 1945-49 and 1950-54 were, respectively, 13 and 15 These figures do not support the suggestion that "for practical purposes they (bladder cancers in chemical workers) have been prevented and eliminated" (Parenthesis inserted)

POSTOPERATIVE VENOUS THROMBOSIS

SIR,—I welcome D Rivlin's letter[5] It is sad to read that "it is extremely doubtful whether the incidence of postoperative venous thrombosis is diminishing" That this proves that early ambulation has been a failure would be a very erroneous conclusion The real motive of early ambulation seems to have been grasped by very few people Much thrombosis is of necessity present after operation or childbirth It is the spread of this process into adjoining streams that must be prevented and, unfortunately, most of the conditions favouring this spread are present after operation, foremost among these is the slowing of the blood-stream which allows the platelets to silt out and set into action the process of clotting This blood-clot is inside an undamaged vein, is not firmly adherent, and is easily detached

The rate of flow can be increased by muscular activity and by antigravitational methods Gravity is counteracted by raising the foot of the bed about 9 in , and ankle and knee exercises in bed or walking will increase muscular activity Not all patients are fit to get up soon after a major operation, yet many enthusiasts impose this as a rigid routine For such people, far more benefit would be gained by knee and ankle movements in bed for three minutes in every hour, than by getting them up In fact, the latter can surely be harmful when the patient is frail and in considerable discomfort, and especially so when she has merely been lifted into a chair for some five minutes and then lifted back again As Dr Rivlin says, this is often described as early ambulation There is no ambulation, and in fact the venous return is less efficient than it is in bed with the foot raised I would utter one other word of warning, against the increasingly popular practice of half the ward sitting around the fire together for most of the evening Psychologically, this may be beneficial, but patients allowed the privilege should be warned that it is only on condition that they do frequent knee and ankle exercises

[5] Rivlin S *Lancet* 1957, ii 1290

Thrombotic complications are four times as common in gynæcological operations Surely this is because movements of lower limbs cause much more discomfort after lower abdominal operations and certainly after perineal operations, immobility is the inevitable result

The peak of post-operative thrombosis is at about the tenth to twelfth day, and this coincides with the highest levels of platelet-count, platelet adhesiveness, and plasma prothrombin, a plea is long overdue, therefore, to aid venous return from the legs after operation for at least two weeks This should be achieved by exercises, bed raising, and, of course, early ambulation if the conditions are suitable

London, N W 1 E R REES

OSTEITIS PUBIS

SIR,—I recorded[1] in 1953 that this condition may be found in about 4% of the "rheumatoid" affections of the skeleton, following trauma or sepsis associated with any operations on pelvic structure, and may have more serious extensions than described, for infection of the periosteum may lead not only to the radiographic signs in the symphysis but to signs of ischial bursitis, septic arthritis of the hip, or sacro-iliac joints Though it is often the baffling, painful, and tiresome complication described by your correspondents (Jan 8), it may be painless when first discovered by X-ray examination and may end in fusion at the affected joints, chronic arthritic changes, or, more fortunately, complete resolution

Birmingham JAMES F BRAILSFORD

THE CHECK-VALVE MECHANISM AND THE MEANING OF EMPHYSEMA

SIR,—Consideration of the ætiology of diffuse hypertrophic emphysema has for long been a powerful stimulant to speculation, and the multiplicity of hypotheses emphasises, as a kind of Volker's Law, that we do not know the answer Two types of mechanism may, separately or together, be causative firstly some change in the alveolar wall making it more liable to damage and rupture, and secondly an excessive strain to which "normal" alveoli are subjected and which overinflates and permanently deforms them In his paper in your issue on Jan 11, Dr Lister argues convincingly that diffuse hypertrophic emphysema is usually preceded by bronchitis and bronchospasm There is, however, little experimental evidence to support his conclusion that there is a widespread check-valve mechanism (allowing air to enter pulmonary units but not to leave) and that these units first become overdistended and then emphysematous It is important to state the difficulties in accepting this view

It should first be emphasised that a *uniform* diffuse condition cannot cause overdistension of the airsacs, since the distension must remain within the limits of a person's vital capacity and "healthy alveoli cannot be ruptured by any physiological range of pressure" But if only some pulmonary units have check valves then we have to find a mechanism which will overdistend these but not adjacent alveoli The amount of air entering an airsac will depend mainly on three factors the pressure-drop through the air passage, the resistance to flow through the airway, and the stiffness of the alveoli beyond It is fundamental to the mechanical explanation of emphysema that, in the first instance, the alveoli are of normal stiffness (or compliance, to use current terminology), but even if it is not constricted, a bronchiole or alveolar duct with a check valve will almost certainly have greater resistance to air-flow than a normal bronchiole, unless one regards the valve as similar to a pea in a whistle Furthermore, if the valved unit becomes distended the pressure-drop tending to inflate it will be less than for adjacent unvalved units In other words the "normal" airsacs will be ventilated to a greater extent than the valved ones, which can only be inflated to the maximum static elastic pressure of the lungs which we know they can withstand without rupture

Dr Lister thinks it more likely, however, that the valved units are overinflated by positive pressure within the large airpassages in coughing, "as in pumping up a tyre" But the intrapulmonary pressure must rise with the intratracheal pressure in the expiratory phase of coughing, so that there is no pressure-drop to pump air into the alveoli Even were there such a force it would tend to overinflate "normal" units rather than valved ones, for the reasons given above Furthermore, if the entire contents of the air-passages (150 ml) could in some way be pushed into the alveoli (2500 ml) this would cause little extra distension

There are three possibilities which might resolve the problem

(1) If in the initial changes in diffuse hypertrophic emphysema some alveoli are so damaged as to be less stiff (more compliant) than others, these would then tend to overinflate, the mechanical factors would then be secondary to earlier structural changes, and it is not necessary to incriminate check valves to explain progress of the disease

(2) If units containing check valves have a lower resistance to air entry than "normal" units It is difficult to conceive such a mechanism, and if, as one suspects, the contrary is true the mechanical forces described above would tend to distend "normal" alveoli rather than valved ones

(3) If the alveolar walls are damaged by maintained pressures which do not cause harm when applied transiently in normal breathing Such pressures might be found beyond check valves in the early stages of emphysema

These are theoretical considerations, but the possibilities described above should be susceptible to experimental test In the meantime, the evidence for a check-valve mechanism in the early stages of diffuse hypertrophic emphysema is very largely based on speculation, and it is important to emphasise the difficulties inherent in this theory

St Bartholomew's Hospital Medical College, London, E C 1

G C R MORRIS
J G WIDDICOMBE

INCIDENTAL DANGERS OF X-RAY THERAPY

SIR,—Not only the electrocardiographic changes mentioned in your leading article of Jan 4 but also actual cardiac infarction may follow therapeutic irradiation of the thorax Although the myocardium resembles skeletal muscle in its resistance to X-ray damage small and medium arteries are sensitive and can become occluded by the intimal proliferation described by Tricot et al[1] or perhaps by a similar fibrinoid necrosis to that observed by Professor Wilson and his colleagues (Jan 4), in the kidney

In two cases under my observation extensive infarction occurred six months after irradiation[2] The attacks were of great severity, accompanied by disturbances of conduction, and were followed by a degree of clinical and electrocardiographic recovery that one could not expect after atheromatous occlusion Both patients were women under 50 who had had no previous angina

The long interval is interesting in the light of Professor Wilson's finding of delayed structural changes in the kidney and corresponds with that elapsing before the post-radiation mediastino-cardiac reaction of Blemenfeld and Thomas [3] and Rose and Wolferth [4] It may well obscure a relationship that is commoner than either radiotherapists or " the neighbours " realise

H E S PEARSON

INTRATHECAL PHENOL FOR INTRACTABLE PAIN

SIR,—The report by Dr Nathan and Dr Scott in your issue of Jan 11 corresponds closely with the results obtained during the past year in Edinburgh using a 7½% phenol-'Myodil' solution

As with their material, necropsy has revealed no changes in the spinal cord, its coverings, or nerve-roots which could be attributed specifically to the effect of the injected material

However, 4 patients had their spinal cords exposed at the site of injection within two to four weeks of the injection and each showed a marked localised arachnoiditis Over a distance of about two inches the arachnoid was quite opaque and pink and adherent to the dura and underlying structures, making exposure of the spinal cord tedious

So far, no patient subjected to this form of treatment has developed signs suggestive of a progressive adhesive or obliterative arachnoiditis following the injection, but until a sufficient period of observation has been completed it would seem to be prudent to restrict the intrathecal use of carbolic acid dissolved in myodil to the relief of pain of malignant disease

Department of Surgical Neurology,
Royal Infirmary, Edinburgh

ALLAN S BROWN

A PLASTIC APPROACH TO SURGERY

SIR,—It is surprising that Mr Heanley (Jan 11) as a plastic surgeon should advocate the making of incisions in the direction of Langer's lines, for in the face, where the best cosmetic result is particularly desirable, the line of election for a scar bears no relation to Langer's lines

As Le Gros Clark [5] has pointed out

> " with the movements of facial expression, flexure lines appear momentarily in the skin at right angles to the pull of the fibres of cutaneous muscles In other words, their pattern is determined by the arrangement of the underlying musculature With advancing age, as the result of the progressive loss of the elasticity of the skin, these creases become established as permanent wrinkles "

The illustrations of Kraisse [6] have shown convincingly that at many points the direction of the lines of election and that of Langer's lines are at complete variance and it would appear that when they do coincide this is quite fortuitous

The continued lip-service paid to Langer's lines in most surgical textbooks would suggest that these facts are not widely enough appreciated

IAN A MCGREGOR

CHRISTMAS QUIZ

DR N HOWARD-JONES writes

"Supplementing Dr Gurney Smith's correction (Jan 4, p 58) to the excellent Christmas Quiz provided by Dr Ffrangcon Roberts, I would point out that the *St Bartholomew's Hospital Reports* of (as far as I recollect) the 1870s contain a most amusing article by Robert Bridges on the casualty department of his hospital The answers to the quiz contain another slip 'Jesuits' bark' was not quinine, but the bark from which quinine and other cinchona alkaloids were subsequently isolated "

Obituary

JAMES COUPER BRASH

M C, M A, M B Edin, M D Birm, LL D St And, D Sc Leeds,
F R C S E

Emeritus Professor Brash died at his home in Edinburgh on Jan 19, at the age of 71 He was one of the great figures and personalities in British anatomy, and his death will cause many practitioners of medicine the world over to feel a deep sense of personal loss

He was born in Helensburgh, and was educated at George Watson's College and Edinburgh University where he entered on an arts course The knowledge of literature, philosophy, and Latin that he then gained formed the basis for his own philosophy of life He recommended others to cultivate, as he himself certainly did, the tranquil mind, the quality of imperturbability and calmness in times of emergency These indeed formed the theme of his promoter's address to the new graduates in medicine in Edinburgh in 1940

After graduating M A, Brash entered on a combined science and medical course in which he distinguished himself in many subjects and extracurricular activities He was prominent in several student societies and became senior president of the Students' Representative Council After graduating M B in 1910 he became house-physician in Edinburgh Royal Infirmary to the late Sir Thomas Fraser In 1911 he joined the anatomy department of Edinburgh University as a demonstrator under the late Prof D J Cunningham—and this connection was always a matter of pride to him From Edinburgh he moved to the anatomy department at Leeds, but in 1914 he joined the R A M C, and while with it served in France and Belgium, attained the rank of major, and was awarded the M C Returning to academic life he was later translated to Birmingham, where he became professor of anatomy and dean of the faculty of medicine He was responsible for the planning of many of the developments that led to the formation of the new Medical School in Birmingham, and for such responsibility he was eminently well qualified He succeeded Prof Arthur Robinson in the chair of anatomy at Edinburgh University in 1931, and for 23 years he laboured ungrudgingly and without stint for his alma mater His lectures were always most carefully prepared expositions of the subject with which he was dealing, and on occasions he was carried away by his own enthusiasm He and the late Dr E B Jamieson established a close and firm friendship that matured over the years, and they were co-editors of the 7th and 8th editions of *Cunningham's Text-book of Anatomy* and also were co-editors of two editions of *Cunningham's Manual of Practical Anatomy* The last editions of the manual were, however, entirely Brash's work, and he was also sole editor of the most recent edition of the textbook

His main scientific interest was the development and growth of bone, and his Struthers lecture on the subject in 1933 to the Royal College of Surgeons of Edinburgh is now regarded as a classical study Much of his original work was associated with the growth of the jaws and palate, and he had a particular interest in the ætiology of irregularity and malocclusion of the teeth The mechanism involved in the movement of the teeth during growth of the jaws always fascinated him and his madder preparations threw great light on the subject His eminence as an anatomist was recognised by the Anatomical Society when he was elected president for 1945–47 and also by the Universities of St Andrews and Leeds from which he received honorary degrees His anatomical skill was brought to the notice of the general public through his researches and meticulous work in connection with the

Ruxton murder case, and he and Prof John Glaister published a volume in 1937 dealing with the medicolegal and other scientific aspects of this case In 1955 he published an important text on the neurovascular hila of limb muscles

R W, an Edinburgh colleague who migrated across the Firth of Forth, writes

Professor Brash's interests were multiple and on golf course and in trout stream he showed the same enthusiasm as at work in his laboratory His sense of pawky humour was a feature of his lectures and after-dinner speeches and through it he relieved the tenseness of many an examination He was a man who always gave more than he received and in doing so gave himself great pleasure, students without number and graduates sought his counsel and advice knowing that in doing this they would receive an opinion that would be in their best interests For over 45 years he owed much to Mrs Brash and through her he came to have a deep love for St Andrews and its University

THOMAS KIRKPATRICK MONRO

M A, M D Glasg, F R F P S

Dr T K Monro, emeritus regius professor of the practice of medicine in the University of Glasgow, who died on Jan 10 at the age of 92, had won an honoured place in Glasgow by the kindliness and skill with which he served the city's patients and the learning and humanity which he offered the students in the city's medical schools His interests as a physician and a bibliophile were happily joined in his famous collection of editions of *Religio Medici*

He was born at Arbroath, where his father, Dr William Monro, was in practice After graduating M B from the University of Glasgow in 1888 he continued his medical studies in Vienna, Berlin, and Paris Soon after his return to Scotland he became pathologist to the Victoria Infirmary in Glasgow He had held the chair of medicine at St Mungo's College and a clinical lectureship at the Royal Infirmary for over ten years when in 1913 he was appointed to the regius chair at the University

His writings on his own subject included his *Manual of Medicine*, his *History of the Chronic Degenerative Diseases of the Central Nervous System*, and a monograph on Raynaud's Disease His book on the *Physician as Man of Letters, Science, and Action* happily presented his profession to a wider circle of readers He retired from his chair in 1936, and the following year the University of Glasgow conferred on him the degree of LL D Two years later the Royal Faculty of Physicians and Surgeons elected him to their honorary fellowship, an unusual distinction for one who had already served as their president

The following tribute is taken from the address which S A gave at Professor Monro's funeral on Jan 14

Thomas Kirkpatrick Munro found his life work and his inspiration in the day-to-day care of sick people in the hospitals and homes of this city A supreme master of the art of clinical practice, he enhanced the value of his skill by kindness born of compassion, and his whimsical sense of humour endeared him to his patients and to his students He was an outstanding teacher—especially for those students sensitive to the great adventure opening before them in this realm where science merges into art Acutely aware of the needs of the individual patient before him, it was nevertheless by a light more remote yet more vivid that he saw the detail of his task

His skill and shrewdness and humanity at the bedside were the blossom of a fine intellect nurtured in the climate of true learning he read his classics in the original and refreshed his mind with music, history, and mathematics, and in the twilight of his later years, though frail and blind, by the sense of touch he lived among his favourite authors and walked with greatness He loved the open country, the wind and the rain, and while walking and angling he cherised the boon of solitude Topics which might seem remote from the mind of a scholarly physician came within the ambit of his encyclopædic knowledge he could startle the expert by dissertations on locomotive construction, and others he would entrance by his devotion to the circus It would be a fitting tribute to his diverse accomplishments if they were to be recorded in his own book—*The Physician as Man of Letters, Science and Action*—for in these pages he reveals his affinity for the man of many parts So notable and ardent à bibliophile inevitably grows into his books The pages of the *Religio Medici* and *Christian Morals* were so close to Thomas Monro that he seemed to breathe the same air as Sir Thomas Browne, and with him might well have said—

> Some things are dictated for our instruction and some
> acted for our imitation
> He honours God, who imitates him, for what we
> virtuously imitate we approve and admire

CHIRANJI LAI PASRICHA

M A, M B Cantab

Lieut -Colonel Pasricha, who died in London on Jan 11, was a former director of the School of Tropical Medicine at Calcutta From 1948 to 1955 he was medical adviser to the High Commissioner at India House, and he was often to be seen at scientific and social gatherings of doctors in London

He was born in the Punjab, and educated at Leys School and Caius College, Cambridge, where he took a first in the natural sciences tripos He qualified in 1920 from St Bartholomew's Hospital, where he won the Shuter scholarship Soon afterwards he passed into the Indian Medical Service and later saw service in China as well as in India In 1933 he became professor of pathology and bacteriology at the Calcutta school In 1939 he was awarded the Minto medal for medical research His work included investigations into the treatment of cholera with the newer sulphonamides, and on choleraphage, snake venoms, epidemic dropsy, and sprue He succeeded the late L E Napier as director of the school in 1945, and he also was superintendent of the Carmichael Hospital for Tropical Diseases in Calcutta During the late war, he was A D M S at Army Headquarters, New Delhi, and at this time he largely rewrote the *Field Service Hygiene Handbook* (1945)

In 1948 he came to London as medical adviser to the High Commissioner for India P H M-B writes

Pasricha was an admirable public-relations officer by reason of his friendliness, his accessibility, and his attraction to the British way of life, and adherence to its ideals as well as to those of Indian culture It was always an experience to get into touch with him and thereby to imbibe some of his vigour and enthusiasm At medical meetings his tall, erect military figure was welcome, and the benignant smile which lit up his face was indicative of the character of this popular man He always remained a loyal friend of this country, a devoted and loyal son of Cambridge, and proud of his associations with St Bartholomew's

Notes and News

ONCHOCERCIASIS

AT a meeting of the Royal Society of Tropical Medicine and Hygiene in London on Jan 16, Dr A R D **ADAMS** (Liverpool) opened a symposium on onchocerciasis with a short general account of the disease adding that he had seen only one instance of serious eye lesions in his considerable series of European cases

Prof A W **WOODRUFF** commented on the rarity of ocular lesions in Africans examined in Calabar, where almost all were infected with the disease On the other hand eye lesions—mostly slight—were found in 12 out of 76 patients (72 Europeans) seen in London Eye lesions might therefore be present in light infections and absent in heavy infections possibly the high gamma-globulin content of the sera of Africans, so constantly exposed to multiple infections, provided a protection. It seemed that some other factor was needed to produce blindness Onchocerciasis might be suspected . there was unexplained pruritus, rash, eosinophilia, or eye disease in persons from the endemic areas, and filarial complement-fixation test and skin tests were useful Diethylcarbamazine would kill not only the microfilariæ but also the adult worms, if enough was given This was disputed by Dr F **HAWKING**, who, though acknowledging the drug's great value against microfilariæ, did not find it lethal to the adult worms For this suramin was necessary

The strongest critic of the blindness concept was Mr D P **CHOYCE**, who showed slides illustrating those lesions of the anterior segment of the eye which are admittedly due to onchocerciasis—keratitis commonly, iritis more rarely—but which in the Cameroons did not often lead to more than slight interference with vision He did not think that this infection could cause cataract The lesions of the posterior segment which caused blindness and which had been attributed to onchocerciasis—optic atrophy, retinal degeneration—were, he thought, probably of different ætiology, and there was no good evidence that they were onchocercal Optic atrophy was caused by vitamin deficiencies, syphilis, and other conditions common in Africa, and the form of choroidoretinal degeneration seen there was remarkably similar to the hereditary diseases known in Britain and transmitted as a genetic dominant Moreover, as microfilariæ of *Onchocerca volvulus* were not found in the blood-stream, it was difficult to understand how they could gain access to the optic nerves and choroid Mr Choyce concluded therefore that onchocerciasis was probably not a serious cause of blindness, though he admitted that it might have an adverse effect in trachoma, leprosy, and other affections of the eye

Dr W E **KERSHAW** (Liverpool) agreed with this general conclusion, on epidemiological grounds after investigations in the Cameroons The anterior eye lesions were related to the intensity of infection but were not blinding lesions, but the incidence of posterior eye lesions, the blinding lesions, bore no relation to intensity of infection Dr R S **BRAY** reported work done in Liberia in which no blindness was found in a group of African onchocerciasis patients in whom there was much deficiency disease

These arguments were not enough to shake the belief of several speakers who had lived in the onchocerciasis areas of West Africa Dr B B **WADDY** thought that heavy infections in childhood might lead to blindness in later life, and that onchocerciasis could cause cataract Optic atrophy might possibly be related to extensive use of tryparsamide for sleeping-sickness Lieut-Colonel J H **WALTERS** recalled the high incidence of posterior eye lesions in peoples living near rivers, who left those parts on that account Optic atrophy certainly might be due to syphilis, but that was commoner in towns than in rural areas such as those in which onchocerciasis flourished Dr J L **MCLETCHIE** pointed out that blindness was common in Northern Nigerian onchocerciasis areas, which were in a dry climate, but rare in the south where the climate was more moist.

Dr A B **RAPER** showed photographs of a condition of dwarfism, in children in the onchocerciasis areas of East Africa, which had very characteristic features—muscular wasting, stunting of growth, kyphosis, and a characteristic facial profile All the patients were heavily infected with onchocerciasis

PATIENTS' PARLIAMENT

UNDER what he calls the " grandiloquent " title of " creative group therapy " Dr George Day describes [1] efforts at self-help by the patients at a private sanatorium in Norfolk Irritated by high prices in local shops, some of the patients opened one of their own, and, having no overheads, it prospered Each corridor supplied a voluntary shopper—one of the ambulant patients—who ran errands for bedridden neighbours One such volunteer from each corridor took a seat in the " Patients' Parliament ", which met weekly and in the course of some ten years spent the shop's profits on books, games, records, broadcasting equipment, a television set, a film-projector, a gramophone, a typewriter, and such useful items as irons and hairdryers Less to raise funds than to give everyone a feeling of participation, half-a-crown a month was levied on all patients who could conveniently afford it

Early in its career the Parliament, which was not elected but self-perpetuating by cooption, began to hear and discuss patients' complaints and suggestions Dr Day acted as Speaker—literally, for he could speak but not vote He had a veto on medical grounds, and at first put right proved complaints, later these tended to be solved by the patients A new patient would find himself visited by ambulant ones as a routine—to see whether he wanted anything, not to gossip—and very quickly felt at home Thus the spirits of self-help and of help-your-neighbour were fostered, and morale was high

MEDICAL FILM

A NEW film, *Ergot—The Story of a Parasitic Fungus* (16 mm , sound, colour, 26 minutes, Britain 1958), traces briefly the discovery and therapeutic use of ergotamine and ergometrine

The film opens with numerous references to ergot poisoning from the 16th century onwards Half the film is then devoted to the life-cycle of the parasite and methods of growing it under controlled conditions for medicinal purposes The symptoms of migraine are set out, and reference is made to a preparation of ergotamine tartrate including drugs to counter its side-effects Prof Chassar Moir describes the discovery of ergometrine in 1935, and finally a patient being delivered in the maternity department at University College Hospital, London, is seen to be given an intravenous injection of the drug

This is a good film, particularly interesting in the sequences on the history of ergot poisoning and on the cultivation of the parasite Douglas Fisher s colour photography is superb, and the commentary is informative

Copies may be obtained free of charge from the Wellcome Film Library, 183, Euston Road, London, N W 1

Royal Microscopical Society

Mr John Bunyan, L D S , Leverhulme research fellow at St. Mary's Hospital Medical School, has been elected president of the society

The Guild of Teachers of Backward Children

This guild will hold its second national conference at Goldsmith's College, London, on April 18 and 19 The hon secretary of the guild is Mr S S Segal, 10, Fielding House, Boundary Road, N W 8

Royal Commission on Remuneration

The Royal Commission on Doctors' and Dentists' Remuneration will hold a public hearing on Friday, Jan 31, at Church House, Great Smith Street, London, S W 1, at 11 15 a m Representatives of the Royal College of Physicians of London have been invited to attend

Training Posts in Hospital Administration

Applications for a further 16 training posts for prospective hospital administrators are invited

The posts are open both to young officers already employed in the National Health Service and to graduates and professionally qualified people who wish to make hospital administration their career Further particulars may be had from the Ministry of Health, Savile Row, London, W 1

College of General Practitioners

Butterworth gold medal—The subject for this year's prize essay, by a member or associate of the college, is Second Opinions Further particulars may be had from the chairman of the awards committee of the college, 41, Cadogan Gardens, Sloane Square, London, S W 3 Essays must be submitted not later than Sept 20

Royal Air Force Appointments

Air Commodore G A M Knight has been appointed deputy director-general of medical services in the Royal Air Force with the acting rank of air vice-marshal, in succession to Air Vice-Marshal L M Corbet who is retiring Group-Captain J F Dales has been appointed principal medical officer, 2nd Allied Tactical Air Force, with the acting rank of air commodore

Confederation of Health Service Employees

At a conference of the confederation held in London on Jan 15 delegates rejected a proposal to impose a national ban on overtime for all members (*Times*, Jan 16) Since September temporary bans on overtime have been imposed on mental hospitals in different parts of the country, and the results of these local bans were criticised at the meeting Some speakers doubted whether a ban on overtime would now be an effective way of showing members' discontent A delegate said that, owing to a change in conditions of the labour market, hospitals at Lincoln, and he believed elsewhere, now had more staff than at any time in the past six years

World Health Organisation

The Republic of Czechoslovakia has resumed active participation in the work of the World Health Organisation Czechoslovakia became a member State of W H O in 1948, but in 1950 discontinued active participation During 1957 Albania, Bulgaria, Poland, the U S S R and Rumania announced their resumption of active participation in W H O Member States which still remain inactive are Hungary, Ukranian S S R , and Byelorussian S S R

Executive Board—The twenty-first session of the Board began in Geneva on Jan 14, under the chairmanship of Sir John Charles The chief item on the agenda is the examination of the Director-General's proposals for programme and budget for 1959 Emergency supplies of vaccine were approved for Ceylon, where floods have covered a third of the island's surface, 300,000 people are estimated to be homeless, and epidemics of typhoid and cholera are feared Half a ton has already been sent, and another quarter of a ton will soon follow Part of the cost will be reimbursed by Ceylon

---

CORRIGENDA *Phæochromocytoma of the Urinary Bladder*—In the article by Dr B R B Lumb and Dr G A Gresham (Jan 11, p 81) the year in the first line of the fourth paragraph of the case-report should have been given as 1956 In the fourth line of that paragraph and in the penultimate line of the sixth paragraph the noradrenaline level was in microgrammes In fig 2 the specimen was reproduced at less than actual size

The Check-valve Mechanism and the Meaning of Emphysema—In Dr W A Lister's article (Jan 11, p 66) the illustration shown as fig 2 was in fact fig 1, and that shown as fig 1 was fig 2

BETWEEN GUESSWORK AND CERTAINTY IN PSYCHIATRY*

AUBREY LEWIS
M D Adelaide, F R.C.P
PROFESSOR OF PSYCHIATRY, UNIVERSITY OF LONDON

(concluded from p 175)

An effect of growing, but excessive, confidence in the power of psychiatric treatment is discernible in the changing attitude towards those who are delinquent or may become so The recent Royal Commissioners on the Law relating to Mental Illness and Mental Deficiency assumed that doctors can tell which persons of psychopathic personality will benefit by treatment, and what treatment will be needed, consequently they recommend that compulsory powers to force a psychopathic patient into hospital should be used only when it is "clearly established" that he needs a particular form of treatment, which the hospital in question can provide, they recommend more extensive compulsory powers over adolescents and young adults who show psychopathic personality, because "it is generally agreed that treatment or training is most likely to be successful if it can be given at this stage" It may well be that both these assumptions about the benefits of treatment for psychopaths will turn out to be warranted but as yet they rest on the certainties or the clinical impressions of those who took part in the treatment and on unchecked appraisal of the association between outcome and treatment No controlled studies, of adequate size, have been carried out, and many of the difficulties which have so far precluded this were demonstrated in the investigation of a cognate problem—whether juvenile delinquents and "pre-delinquents" benefit from having a kindly older person to whom they can turn for friendship and guidance Richard Cabot had supposed they would, an elaborate inquiry, with well-matched controls, was carried out to test his hope This investigation had nothing to do with psychiatric treatment, nor were psychiatrists concerned in the analysis of its findings, but it afforded a model of honest, hypothesis-testing, longitudinal study of the effects of deliberate intervention It exposed weaknesses in design and execution which can be foreseen now and guarded against, it demonstrated that social investigations concerned with human beings over a period of years cannot be carried out wholly according to plan, yet can be made to answer a correctly stated question, and it threw light on our ability to predict behaviour. Prognosis is more difficult in psychiatry than in other branches of medicine, as Kraepelin insisted some psychiatrists, it is true, pride themselves on their gifts in this direction, but their complacency usually has weak foundations Criminologists have been in the same boat

In the Cambridge-Somerville study just referred to, three experts in criminology (one of them a psychiatrist) predicted what would be the later social adjustment of the 782 "difficult" or "pre-delinquent" boys, aged about 9 years, who were reviewed for the study, a similar prediction was made by the children's teachers, and it emerged that there was a correlation coefficient of 0 48 between the actual outcome on the one hand and the predictions both of the experts and of the teachers on the other In other words, the predictions were above what would occur by chance, but experts in juvenile delinquency were no better at predicting what would happen to these children than were their school teachers Moreover, both the teachers and the experts predicted more delinquency than actually occurred, so if there had been no "untreated" group for comparison they might have inferred—mistakenly—at the end of the investigation that the discrepancy between their predictions and the actual outcome was attributable to the benefits of the "counsellor" scheme of treament provided (Powers and Witmer 1951)

The most recent and sophisticated prediction study is Mannheim and Wilkins's inquiry into the effects of borstal training Besides constructing prediction tables which they validated, they found it expedient, like others before them, to provide individual case-studies—i e, to combine the clinical with the statistical method, in order to "demonstrate the variety of factors which, combined, may produce the same statistical score, to work out a typology of cases related to the various score classes, and to make a special study of atypical cases, i e, cases who, in spite of favourable statistical scores, actually become failures, and vice versa" In their view the control technique, though in many ways indispensable, is insufficient as the only method of evaluating the diverse patterns and changes in the behaviour of individuals (Mannheim and Wilkins 1955) But Mannheim, in expressing this view apropos of the Cambridge-Somerville study, concluded that such investigations will have to be "in keeping with the experiences of experimental social science rather than those of medicine" (Mannheim 1953)

This seems an innocuous conclusion But it contains the chief elements of a vital controversy Psychiatry is, like criminology, a form of applied social science it is also a branch of medicine If there is an intrinsic opposition or sharp difference, as Mannheim implies, between the methods appropriate to study of social experiments and those of medicine, psychiatry will be pulled hither and thither, in a bewildering zigzag I do not believe there is such an opposition, but the literature might suggest it—and the progress of psychiatry does look a little indecisive and wobbly at times The problem is to be found in the uniqueness, the singularity of each individual

In the practice of psychiatry, attention must be concentrated on the individual Because he is unique and extremely complicated, he does not seem wholly catchable within a scientific net The succession of events which pertain to the medical, as to the social or psychological, course of an individual's life can, it is true, be predicted to some extent, and designedly influenced, by applying general principles to the historical and observational data we have about him but there is still something over, consequently intuitive processes often play a large part in determining the physician's prognosis and treatment—especially in psychiatry The doctor's procedure may hardly include at all the strict deductive application of a general theory to a particular, narrowly stated case, and it differs manifestly from that of the experimental biologist who does his utmost to get rid of uniqueness in his experimental animals This difference applies to the practice of psychiatry But it does not apply to the psychiatric investigator who must concern himself with what is common to human beings, or to classes and subgroups of human beings

---

* The Bradshaw lecture for 1957, delivered before the Royal College of Physicians on Nov 7

* * *

The controversy is not between medicine and the social sciences, or between medicine and the biological sciences, but between two schools of thought within the social sciences Their debate has enlisted some notable disputants There is guerilla warfare between the adherents of the "nomothetic" school, which seeks general laws and employs the procedures of the exact sciences, and the "idiographic" school, which endeavours to understand some particular event Both approaches, as Gordon Allport has urged, have value in studying personality But the proportion of idiographic to nomothetic study can be excessive and there can be little question that this has been the case in psychiatry Hence its weakness on the very ground where idiographic study should be most potent—the understanding of individuals to such a degree that their behaviour can be predicted

Meehl, in a thoughtful monograph on this matter, collected all the published instances in which predictions arrived at by the skilled judgment of a clinician were compared, as to their correctness, with those arrived at mechanically by someone who had not seen the patients but who made appropriate calculations In all but one of the twenty studies examined, the actuarial or cookery-book approach yielded results as good as those of the clinician, or better (Meehl 1954) It would be imprudent to draw from this the conclusion that clinical prognosis is a superfluous exercise, and that prediction had better be handed over to the clerks and computors impartial judges like Vernon have pointed out that the clinical method—and in particular the clinical interview—has advantages which the actuarial method, based on psychological tests and biographical items, does not possess

Informative as the idiographic approach has proved, and fertile as it will doubtless continue to be, it contains no built-in safeguard against persistent error Such safeguards are essential, for, as Karl Popper puts it, "if scientific objectivity were founded upon the individual scientist's impartiality or objectivity, then we should have to say goodbye to it" Yet the safeguards contained in the scientific method are repugnant to some who devote themselves to psychotherapy, and their argument against it always harks back to the uniqueness of the individual Thus C G Jung declares that

> "from matters of individual psychology science ought, in fact, to withdraw For, to speak of a science of individual psychology is already a contradiction in terms It is only the collective element in the psychology of an individual that constitutes an object for science, for the individual is by definition a unique reality that cannot be compared with anything else"

This is an obscurantist argument Because an individual is a unique reality, it by no means follows that he cannot be compared with anything else every individual plant, every individual animal is a unique reality but not therefore exempt from comparison and collective study The argument is a reversion to the claim, so often voiced during the controversies about Evolution, that man is, by his nature, fundamentally distinct from all other creatures and an improper subject for comparative study The opponents of the evolutionary theory refused to consider what human beings have in common with other living creatures the argument put forward by Jung ignores what human beings have in common with each other Psychology has in fact concerned itself with individual differences, and has had notable success It may be that the difficulty is verbal, and that Jung means by the psychology of an individual the study of just that which is the essence of each person's total personality, something that would be shattered by analysis and resolution I doubt, however, if his statement is merely a truism, as this explanation would suppose

The dispute has many facets For some, it can become a theological issue For others, the distinction is between the generalising sciences and the historical sciences Popper, whose analysis has been so searching, put forward the view that whereas the generalising sciences are interested in testing universal hypotheses having the character of natural laws, and in predicting specific events, the historical sciences are concerned in explaining past specific events by means of interpretations and specific hypothetical statements about "causes" This view, which is in keeping with Max Weber's, would put clinical psychiatry in the historical class, in so far as it is directed at understanding morbid behaviour, trying to uncover what Jaspers in his elaborate exploration of the matter called "verstandliche Zusammenhänge" It would be improper to put all psychiatry in this class, and I would not have laboured this issue if it were not again evident at the present time that there is a strong move away from the search for general laws, and towards preoccupation with the individual Thus Manfred Bleuler, one of the most prominent of European psychiatrists, declared recently that the most essential feature in the recent development of psychiatry has been that the diagnosis of disease has given place to absorption in the personal tragedy of individuals "das Hauptaugenmerk richtet sich auf Einzelschicksale" (Bleuler 1957) The effect of this movement will, I submit, be retrograde

* * *

I have dwelt so far on prognosis and treatment There is another extensive but rather neglected territory in which few psychiatrists tread a confident path—the alleviation of chronic disorders, and especially chronic schizophrenia The word "chronic" has got a bad name, and many think they can dodge its terrors by submitting "long-stay" for it But changing names has always proved a futile game in psychiatry, and the chronic patients, whatever the euphemism applied to them, remain a vast reproach The Chairman of the Board of Control lately reminded us that the number of chronic patients in England and Wales has remained fairly constant throughout the years, at about 130,000, 85% of the patients in the mental hospitals have been there for more than a year, and 60,000, (i e, two-fifths of the whole mental hospital population) have been there more than ten years, 50,000 of these patients suffer from schizophrenia (Armer 1957) Considered in relation to the general population, there are for every 100,000 people over 16 in England and Wales, 270 in a mental hospital suffering from schizophrenia, mostly in a chronic form It is painfully clear that chronic schizophrenia is an outstanding medical and social issue

Some therapeutic zealots believe that if appropriate treatment, especially insulin-coma treatment, had been administered early to these patients, many of them would not have become chronically ill For this belief there is no adequate foundation We must, unfortunately, reckon with the continuance, for decades at least, of this vast company of more or less incapacitated schizophrenics

It is, however, necessary to distinguish between being chronically ill with schizophrenia and having therefore to be in a mental hospital The attitudes of doctors and of society at large determine whether a person with a long-continued mental illness lives in a mental hospital or in the community. The practice of some countries has been towards increasing mental-hospital care, and of others towards keeping it at a minimum. Many communities have been readier to build and equip medical institutions—hospitals as we know them—than to provide hospitals in the older sense—asylums for the infirm and the indigent—and homes in which the patients could find friendly shelter, as at Gheel.

We are now entering a phase in which we shall be directing our efforts towards keeping patients in the community as long as possible, and if they have to come into hospital, towards returning them to the community quickly. The reasons for this are mixed—awareness of the deleterious effects a mental-hospital environment can have however well ordered it may be and aptly designed for the patients' benefit, regard for favourable social influences which independent life in the community affords, even to the mental cripple, economic advantages for the patient, the taxpayer, and the nation, shortage of nurses, and perhaps some changes in the social ethos. The recent Royal Commission expressed this trend of opinion, in its broadest form, in their recommendation—"there should be a general re-orientation away from institutional care in its present form and towards community care."

This is a hopeful change from that overcautious policy which regarded the mentally ill, especially the chronic schizophrenic, as debarred from society so long as delusions, hallucinations, or peculiarities of conduct were discoverable. But the new policy—I call it new but it was advocated as long ago as 1905—could go to extremes and do much harm. It could also lose its impetus and purpose. Reforms that rest on humanitarian impulse have been most powerful for good, especially in psychiatry, but their momentum has often been lost or their drawbacks been perpetuated when the generation of reformers passed away. The chief safeguard against this recurrent backsliding lies in the accumulation of more precise knowledge, permitting generous aims and lofty principles to be translated into regular procedures that will be applicable even when the reformer's driving force has slackened and gone.

* * *

How much do we know about the issues touching on community care for the chronic schizophrenic? As yet little. Shrewd empiricism and clinical intuition provided, so it was thought, all that we needed for the rehabilitation of the chronic psychotic. There have been preliminary sketches but no finished pictures of the effect of hospital environment upon such patients; few studies of how the patients may be selected, and how prepared, for satisfactory life in the larger community; and only tentative cartoons and inadequate blueprints of the domestic, social, and occupational conditions requisite if they are to keep their heads above water when they have left the mental hospital.

It has long been a commonplace of psychiatric thinking that for many patients there is a critical stage in their mental-hospital stay: if the turning-point is not recognised and the patient then discharged, he will subsequently react to his hospital life and surroundings by becoming worse and the chances of his ever leaving will be very small. What truth there is in this, how the favourable phase is to be recognised, what characteristics of the hospital regime need to be altered to make adverse effects less—regarding these questions there is much guesswork, sometimes ill-assorted with a feeling of certainty "on the strength of my thirty years experience, I am absolutely convinced that . . ." A French psychiatrist, P. C. Racamier, wrote a few months ago that there is no creature in the world more sensitive and vulnerable to his human environment than a schizophrenic, and that a psychiatric ward is a two-edged weapon, potentially therapeutic and potentially "le plus remarquable instrument d'aliénation qu'on puisse imaginer . . . surtout pour ces aliénés achevés que sont les schizophrenes." He states the general proposition that autistic isolation is the only stable relation which a schizophrenic can establish with another person, and declares that it is a "law of sociopathology" that the hospital milieu tends to maintain this morbid stability ("Le milieu hospitalier, l'hôpital tout entier, a tendance a maintenir le status quo stable acquis au prix de la chronicité des malades."). A generalisation such as this, derived from a psychoanalyst's experience as doctor in a mental hospital having no unlocked wards, goes much too far, but it suggests some provocative hypotheses.

To state hypotheses and devise suitable experiments in this field of inquiry is a formidable business, as we and others have found. Social experiments in hospitals will seriously effect the daily care and the disposal of patients, put a strain on the attitudes and sense of security of nurses, and perhaps run counter to cherished clinical beliefs. Only those who would not have to carry out such experiments could be disposed to throw stones at doctors, sociologists, and psychologists for not having accomplished the feat yet.

In the investigations which the Social Psychiatry Research Unit has been carrying out, we have found it necessary at each stage to pass backwards and forwards from laboratory to ward and from ward to laboratory, and to pass from both to the outer world where relatives live and conditions of work and daily life may make or mar the chronic schizophrenic's chance of staying outside hospital for good.

First, there was the inescapable problem of ascertaining the patients to be studied, and then matching one group of them with another. Since there may not be agreement as to which patients are properly diagnosed as schizophrenic, some unambiguous and communicable criteria must be used. Psychologists have applied factorial analysis to rating scales of behaviour, and so worked out diagnostic patterns which can be applied uniformly; the use of these minimised the risk that others who replicate the experiments might obtain discrepant results only because their criteria of paranoid and catatonic schizophrenia differed from ours.

When the patients had been selected—they were men who had been in hospital for years—their mental state and their potentialities for life outside the hospital had to be assessed. Clinical data had to be reinforced by observations on the capacity of the patients to learn and to improve their performance at industrial tasks. The reaction-time of schizophrenics, and the effect of distractions and other extraneous stimuli such as noise had to be determined. Differences were found between paranoid and other schizophrenics which made further laboratory experiments necessary. The effect of incentives had likewise to be investigated under laboratory conditions.

Then there were the chronic patients who had left hospital and managed to stay in the ordinary community. For them methods of investigation and statistical analysis were needed akin to those used for prediction work in criminology. A close study of the family relationships of the schizophrenics and of the community's attitudes to mental illness was called for. Such study is best pursued by the combined work of the anthropologist, the psychiatrist, and the social psychologist

The available techniques and theoretical models are not entirely adequate recent work has shown that the methodological problems are still acute It has been necessary from time to time to leave the more practical problems set by clinical observation and therapeutic intention, and to pursue issues of a more general nature, such as the learning curve of the chronic schizophrenic patients, or the methods of measuring change in mental state over a period of time

The history of these investigations is an object-lesson in reciprocity—reciprocity between fundamental and applied studies, between clinician and social scientist, between laboratory and ward

* * *

I have dwelt perhaps too much on the psychological and social side of the picture Psychiatry is not just applied sociology and applied psychology It has its roots deep in medicine, and most of its surest knowledge derives from the bedside and from physiology, pathology, genetics, and biochemistry It has methods of treatment which are of the same stock as those which have proved themselves in other branches of medicine Its only assured methods of prevention concern mental diseases and defects due to known organic causes It is moreover a practical activity, instinct with humane intention the psychiatrist cannot refuse to act in what he judges to be the most helpful way for his patient, even though the therapeutic procedure is empirical and its benefits still dubious Only a detached spectator, god-like above the battle, could expect the psychiatrist to refrain from giving some form of psychological treatment to patients with distressful anxiety or conspicuous hysteria, though he cannot be certain that it will have effect There are some awful warnings of what a craving for certainty can lead to You may remember the philosopher Cratylus who, as Aristotle tells us, decided never to say anything but what was certainly true, and so he ceased to talk at all and confined himself to wagging his finger

Psychiatry suffers much from hopeful illusions and clichés used as incantations, just as a few decades ago it suffered, even more, from pessimistic and resigned inertia Bleuler's monograph on autistic thinking in medicine is a sustained diatribe against the former of these extremes (Bleuler 1927) Adolf Meyer inveighed against the latter of them Into the stagnant bog of nihilism in treatment we are hardly likely to fall again soon, but we are not out of the other danger

It is easy to lay failings like these at the door of psychiatrists, blaming their lack of scientific training, their loose habits of thought, their incuriosity, their passion for psychoanalysis or for physical methods of treatment, their preoccupation with the fascinating art of
ding other people To think this seems to me
and unjust More important than the deficiencies
the inherent complexity of the problems,
as the outset, the fact that the solution
complex and important *depends* upon
ces, which are still in Their
rapid, it is true, psych icular
from strength to strength not

and in the psychiatrist's
the most distinguished of living
has few formulæ, in the sense
olic expressions of relationships
Sociological
discursive, " ture,
the relationshi les not

become lost in an avalanche of words" The sociological analysis of qualitative data does not reside, as some people assume, in a private world "inhabited by penetrating but unfathomable insights The procedure of even the most perceptive of sociologists must be standardizable and the results of their insights testable by others Science, and this includes sociological science, is public and not private" These words of Robert Merton have a familiar ring The study of human behaviour strongly invites private and discursive interpretations the development of the social sciences, pure and applied, has been a struggle to resist the invitation Psychiatry has made one gigantic effort to escape it, but hardly succeeded psychoanalysis, for all its stimulus and scope, has remained rather private and rather discursive

I have not enlarged on the attainments of psychiatry, its solid groundwork of detailed, minute, and orderly observations, its empirical successes, its accretions through application of the basic medical sciences to clinical problems There are large textbooks and innumerable monographs, compilations, and symposia setting forth this stock of knowledge which stands to the credit of psychiatry It is because of it that the psychiatrist, even the self-critical psychiatrist, feels no need to beat his breast and recite penitential psalms when he meets other doctors There are however occasions, such as this lecture offers, when a review of important areas of ignorance and doubt, and of the reasons for them, seems appropriate

Clearly we are a long way from certainty, and when we meet anyone who is sure that he knows how to tackle the problems of mental disorder and to remedy the failings of psychiatrists and psychologists, we may recall Lord Lansdowne's remark "I wish I could be as sure of anything as Tom Macaulay is of everything" Guessing, too, has its perils and its ardours it takes unkindly to the discipline which is good for it Yet between those who are nearly certain and those who guess much there is the bond which Isaac Newton spoke of "I doubt not we have one common design a sincere endeavour after knowledge, without valuing uncertain speculations for their subtleties, or despising certainties for their plainness"

ATHEROSCLEROSIS AND ITS CEREBRAL COMPLICATIONS IN THE SOUTH AFRICAN BANTU

W LAURIE
D S O , M D Glasg , T D D Wales
DEPUTY PROVINCIAL PATHOLOGIST, NATAL

J D WOODS
M B W'srand, F R.F P S , M R C P
PHYSICIAN,

EDENDALE HOSPITAL, PIETERMARITZBURG, NATAL, SOUTH AFRICA

THE high prevalence of coronary-artery disease in more developed communities has focused attention on the causative factors One factor thought to be important is atherosclerosis and hence the interest in the "wide-spread clinical belief that the more severe complications of atherosclerosis such as cerebral and coronary thrombosis are rare among the Bantu" (Higginson and Pepler 1954) This view is supported by Becker (1946), who, in 3000 necropsies on Bantu, held atheroma to have been the direct cause of death in only 0 4%, this is almost the same as Edington's (1954) finding in a survey of necropsies in West African Bantu Again, Humphries (1957) says that in fourteen years' work among natives of South, Central, and West Africa he saw few instances of paralysis due to cerebral hæmorrhage

But Becker (1946) did find atherosclerosis to be common (though not as cause of death) and this seems to have been overlooked For current teaching (e g , *South African Medical Journal* 1957) mentions the "Bantu's relative freedom from atherosclerosis", and Bersohn (1955) is quoted as saying that the aorta of the aged Bantu is comparable with that of a young European Further, according to the Department of Nutrition of South Africa (1956), "heart and arterial disease are very rare among the Bantu" We cannot agree with these views, from our findings in this hospital we consider the true state of affairs in the Bantu to be

(1) Aortic atherosclerosis is common
(2) Cerebral vascular disease is relatively common

Findings

Necropsy Evidence of Atherosclerosis in the Aorta of the Bantu

The serious effects of atherosclerosis are seen in the brain (thrombosis and hæmorrhage) and in the heart (coronary-artery disease)

The findings in table I are drawn from 300 consecutive necropsies in Bantu, over the age of 19, who died in this hospital We have excluded all cases of syphilis or diabetes Necropsies were done (all by one of us) on two-thirds of patients dying in this hospital, which compares well with Higginson and Pepler's (1954) necropsy-rate of 33% Our patients were Bantu from the poorer classes of the midlands of Natal, only 15% came from a city Most live in tribes in rural conditions

Table I shows naked-eye estimates of the degree and extent of atherosclerosis found in the aorta, assessed by a modified form of the grading suggested by Wanscher et al (1951)

Clear = no naked-eye evidence of atheroma
Grade 1 = slight fatty streaking with minimal involvement
Grade 2 = a more obvious atherosclerosis, with plaques tending to be confluent but without obvious ulceration
Grade 3 = severe atherosclerosis including early ulceration
Grade 4 = severe atherosclerosis with ulceration, calcification, and gross scarring

Table I shows that the prevalence of atherosclerosis was significant, even in the younger age-groups, and that its degree and extent increased steadily with increasing age, in the oldest age-groups no-one was found free

TABLE I—PREVALENCE OF AORTIC ATHEROSCLEROSIS IN THE BANTU

Age-group	Sex	Clear (%)	Stage 1 (%)	Stage 2 (%)	Stage 3 (%)	Stage 4 (%)	No of patients	Total
20–29	M	26	35	26	4	9	23	41
	F	28	50	22			18	
30–39	M	25	46	8	4	17	24	58
	F	32	32	30		6	34	
40–49	M	19	25	33	17	6	36	56
	F	15	25	30	30		20	
50–59	M	14	41	21	8	16	37	56
	F	5	16	11	52	16	19	
60–69	M		18	27	30	25	40	59
	F		11	21	31	37	19	
70 and over	M			53	29	18	17	30
	F				77	23	13	
No of patients		44	80	73	56	47		300

Cerebral Complications of Atherosclerosis in the Bantu

In 2000 consecutive necropsies in Bantu patients, cerebral hæmorrhage or thrombosis was found in 31, when cases of syphilis and diabetes mellitus were excluded 5 of these 31 necropsies were limited There were 4 men and 13 women with hæmorrhage, and 6 men and 8 women with thrombosis The high proportion of women is noteworthy, since more men than women are admitted to the hospital

Fishberg (1934) points out that cerebral hæmorrhage is by no means rare in patients without hypertension, but there is general agreement that the tendency to cerebral hæmorrhage seems to be greater the higher the blood-pressure Table II shows the number with hypertension in the 31 cases Hypertension was diagnosed when a blood-pressure of over 145/90 mm Hg had been recorded (Wood 1952)

In the 18 hypertensive patients, the pressures were

Diastolic pressure	*Men*	*Women*
90–110 (mild)	1	4
111–130 (moderate)	1	3
131–150 (severe)	2	4
Over 150 (gross)		3
Total	4	14

Table II shows that up to the age of 55 there is no sex difference in the incidence of cerebral catastrophes with or without accompanying hypertension Thereafter, however, the women are more prone to cerebral vascular disease with and without hypertension This sex difference is the reverse of the findings in all more advanced communities (Loder 1953)

Atherosclerosis was present in all but 1 of the 26 patients in whom a full necropsy was done, with the classification of Wanscher et al (1951), 14 had atherosclerosis of grade 3 or 4, 8 had grade 2, and 3 had grade 1 In half the necropsies, atherosclerosis of the cerebral vessels was gross

In 3000 consecutive necropsies in Bantu in South Africa, Becker (1946) found only 1 cerebral catastrophe, whereas in just under 2000 consecutive necropsies we have found 31 such patients—a prevalence almost fifty times greater than that in Becker's series Further, in our series the percentage with cerebral vascular disease found by us in necropsies in Bantu medical patients is as high as that reported at St Bartholomew's Hospital, London—namely, 3 5% (Wilson 1944)

Discussion

Aortic Atherosclerosis

There are few satisfactory records with which to compare our findings

TABLE II—INCIDENCE OF HYPERTENSION IN THE 31 PATIENTS

Age-group	Total	No with hyper-tension	Men	No with hyper-tension	Women	No with hyper-tension
35–44	8	5	3	1	5	4
45–54	6	3	4	2	2	1
55–64	9	5	3	1	6	4
65 and over	8	5			8	5
Totals	31	18	10	4	21	14

The available techniques and theoretical models are not entirely adequate recent work has shown that the methodological problems are still acute It has been necessary from time to time to leave the more practical problems set by clinical observation and therapeutic intention, and to pursue issues of a more general nature, such as the learning curve of the chronic schizophrenic patients, or the methods of measuring change in mental state over a period of time

The history of these investigations is an object-lesson in reciprocity—reciprocity between fundamental and applied studies, between clinician and social scientist, between laboratory and ward

* * *

I have dwelt perhaps too much on the psychological and social side of the picture Psychiatry is not just applied sociology and applied psychology It has its roots deep in medicine, and most of its surest knowledge derives from the bedside and from physiology, pathology, genetics, and biochemistry It has methods of treatment which are of the same stock as those which have proved themselves in other branches of medicine Its only assured methods of prevention concern mental diseases and defects due to known organic causes It is moreover a practical activity, instinct with humane intention the psychiatrist cannot refuse to act in what he judges to be the most helpful way for his patient, even though the therapeutic procedure is empirical and its benefits still dubious Only a detached spectator, god-like above the battle, could expect the psychiatrist to refrain from giving some form of psychological treatment to patients with distressful anxiety or conspicuous hysteria, though he cannot be certain that it will have effect There are some awful warnings of what a craving for certainty can lead to You may remember the philosopher Cratylus who, as Aristotle tells us, decided never to say anything but what was certainly true, and so he ceased to talk at all and confined himself to wagging his finger

Psychiatry suffers much from hopeful illusions and clichés used as incantations, just as a few decades ago it suffered, even more, from pessimistic and resigned inertia Bleuler's monograph on autistic thinking in medicine is a sustained diatribe against the former of these extremes (Bleuler 1927) Adolf Meyer inveighed against the latter of them Into the stagnant bog of nihilism in treatment we are hardly likely to fall again soon, but we are not out of the other danger

It is easy to lay failings like these at the door of psychiatrists, blaming their lack of scientific training, their loose habits of thought, their incuriosity, their passion for psychoanalysis or for physical methods of treatment, their preoccupation with the fascinating art of understanding other people To think this seems to me facile and unjust More important than the deficiencies of doctors are the inherent complexity of the problems, and, as I said at the outset, the fact that the solution of many of the most complex and important depends upon the social sciences, which are still immature Their growth has been rapid, it is true, psychology in particular has moved from strength to strength but they have not crossed some of the awkward hills and ditches that lie in their path and in the psychiatrist's

One of the most distinguished of living sociologists has said that sociology has few formulæ, in the sense of highly abbreviated symbolic expressions of relationships between sociological variables Sociological interpretations therefore come to be highly discursive, " the logic of procedure, the key concepts, and the relationship between variables not uncommonly become lost in an avalanche of words " The sociological analysis of qualitative data does not reside, as some people assume, in a private world "inhabited by penetrating but unfathomable insights The procedure of even the most perceptive of sociologists must be standardizable and the results of their insights testable by others Science, and this includes sociological science, is public and not private " These words of Robert Merton have a familiar ring The study of human behaviour strongly invites private and discursive interpretations the development of the social sciences, pure and applied, has been a struggle to resist the invitation Psychiatry has made one gigantic effort to escape it, but hardly succeeded psychoanalysis, for all its stimulus and scope, has remained rather private and rather discursive

I have not enlarged on the attainments of psychiatry, its solid groundwork of detailed, minute, and orderly observations, its empirical successes, its accretions through application of the basic medical sciences to clinical problems There are large textbooks and innumerable monographs, compilations, and symposia setting forth this stock of knowledge which stands to the credit of psychiatry It is because of it that the psychiatrist, even the self-critical psychiatrist, feels no need to beat his breast and recite penitential psalms when he meets other doctors There are however occasions, such as this lecture offers, when a review of important areas of ignorance and doubt, and of the reasons for them, seems appropriate

Clearly we are a long way from certainty, and when we meet anyone who is sure that he knows how to tackle the problems of mental disorder and to remedy the failings of psychiatrists and psychologists, we may recall Lord Lansdowne's remark " I wish I could be as sure of anything as Tom Macaulay is of everything " Guessing, too, has its perils and its ardours it takes unkindly to the discipline which is good for it Yet between those who are nearly certain and those who guess much there is the bond which Isaac Newton spoke of " I doubt not we have one common design a sincere endeavour after knowledge, without valuing uncertain speculations for their subtleties, or despising certainties for their plainness "

The Case

Since in published case-histories the doctor rarely appears at all as a person, I had perforce to choose one of my own cases for this study.

I decided to take the first patient I would meet on a certain pre-selected Sunday morning. (I chose a Sunday because I hoped that I would not have to work under as much pressure as on a weekday.)

Early on that Sunday morning the father of a five-year-old girl telephoned me. He said that his little girl had had severe pains in her abdomen since the day before; she had vomited and seemed feverish. I advised him to apply a hot-water bottle to the child's abdomen, and promised to call.

I did not go immediately, but decided to shave, dress, and breakfast before visiting the girl so that I could combine my visit to her with my other visits, without having to go home again. I saw the patient about an hour later. The parents, especially the mother, were very distressed; they feared that the child had acute appendicitis. After examining the child, I told them that I could make no firm diagnosis, and that we could either send the child to hospital, or ask a pædiatrician for a domiciliary consultation. The mother wanted the child to go to hospital immediately, in case an operation were necessary. The child, however, who had listened to the conversation, and who had been in hospital a few weeks before for tonsillectomy, was very distressed at the thought.

In the end, we all agreed to call in the pædiatrician. He came, examined the child with me, diagnosed pneumonia and pleurisy, and suggested antibiotic treatment at home. I gave the child her first penicillin injection, some nursing instructions to the parents, and that completed the treatment for the day. The child eventually recovered and is now quite well.

There had been previous contacts between patient and doctor. The family had moved into the district about six months previously, and become my patients. Their former doctor had advised tonsillectomy, and the child had been placed on a waiting-list. The mother was worried about the child losing her place on the list because the hospital was too far away for her to be taken there. I agreed, after examination of the child, that tonsillectomy was advisable, and was able to arrange it soon in our local hospital. The mother was very grateful for the speed with which arrangements were made.

In this background certain patterns of behaviour had been experienced by everyone concerned, and all had formed certain mental pictures of each other. The mother had seen the doctor fall in with her wishes for treatment of the child, and that he was an obliging man, susceptible to her manifest gratitude. The father, a weak figure, had seen that the doctor complied with his wife's demands. The child had learned that everybody, including the doctor, did what mother wanted. The doctor was pleased, having given satisfaction all round, and acquired a set of " good " (appreciative) patients.

The Patient-group

Although the sick child was the patient to whom the doctor was called, the parents were also involved. They were affected by distressing emotions and had to be dealt with by the doctor therapeutically. Indeed, our case-report would be incomprehensible if it dealt solely with the relationship between the doctor and the child.

Generally, the " patient " is in fact a group of people who are all, in varying measures, affected by the central illness. The peripheral members of the patient-group show mixed somatic and emotional reactions, commonly anxiety, or guilt, or fear of having a similar disease. These reactions both affect the central patient and indicate the need of the peripheral members for treatment by the doctor. To understand and deal with the varied and sometimes opposing needs of the members of the patient-group demands much flexibility.

A few years before the National Health Service, I was called to a child suffering from simple upper respiratory catarrh. To save the working-class mother a further fee, I said that there was no need for me to call again. Some years later I happened to meet the child's grandmother and, remembering that I had not seen the child or the mother for a long time, I inquired after them. The grandmother told me that they had another doctor now, for the mother had felt that by not offering to call again I had not shown enough concern. The child had completely recovered two days after my visit. Obviously, although my treatment of the child had been successful, my treatment of the mother had been clumsy and unsuccessful.

In our present case, had I sent the child straightway to hospital with a bold diagnosis of " (?) acute appendicitis ", the child would have been very unhappy, though the mother's distress would have been relieved. The father would have remained in his ambivalent discomfort of wanting his little girl at home, yet not wanting to contradict his wife. Had I, on the other hand, merely prescribed some appropriate drug and promised to return later in the day, the child would have improved, yet my action would probably have left the mother in a state of doubt and anxiety.

The Immediate Treatment

Our case began with a telephone call, in response to which the doctor advised the application of a hot-water bottle. This simple prescription constitutes the first therapeutic step, the success or failure of which may leave a lasting impression and affect the later steps. It is important, therefore, to examine this advice in more *detail*.

Looking back on the occasion, I remember that the advice was given almost automatically, as if under the pressure of a feeling that something must be done at once in this case. The manifest purpose of the advice was to relieve the child's pain and to reassure the parents. Whether such immediate action and the advice given were best for the child and the parents is a question which can only be answered by scientific argument, and there are undoubtedly as many reasons against as for it. The first treatment decision did not arise out of conscious logical reasoning: it must have been derived from unconscious sources, determined by the personal experiences and attitudes of the doctor, his personality—exactly those qualities that we set out to study.

The doctor showed the same willingness to oblige in the present situation as in his management of the mother's demand for the child's tonsillectomy. He accepted without argument the necessity of visiting the sick child, sensed that the parents were very anxious, and himself became concerned about the child. To continue to be obliging he ought to have visited the child immediately; but he gave himself some very good reasons why he should not. We can see here two conflicting urges: the wish and the disinclination to go immediately.

We might say that the brief telephone conversation about the sick child aroused three major emotions in the doctor.

There was concern about the child, a feeling that, unless something were done, there might be unpleasant consequences—perhaps the child getting worse, or the doctor losing his reputation or the family as patients—in short, *anxiety*.

There was also a dislike of the visit, a hesitation to go immediately, perhaps a feeling that people ought not to bother him so early—or, in terms of basic affects, *hostility*.

Thirdly, there arose the affect of *guilt*, which made him feel that he ought to make up for his not going immediately. He did so by giving the snap advice.

Objectively, there was little cause for anxiety about the child, or for feeling guilty about not going at once. She had been ill for some sixteen hours, and another hour or two would scarcely

Becker (1946), in 3000 necropsies, recorded a high prevalence of aortic atheroma in the older age-groups—e g , 74% in patients over 60, and 56% in patients over 45 He analysed the severity of the lesions in the over-45 group and our findings are set out for comparison our grades 1 and 2 are equivalent to his mild, our grade 3 to his moderate, and our grade 4 to his severe

Degree of atheroma	*Mild*	*Moderate*	*Severe*
Becker s series	58%	16%	26%
Present series	50%	28%	22%

In Becker's series the youngest patient with ulcerative atherosclerosis of the aorta was aged 30, our youngest patient with this degree of disease was 27 Another of our patients aged 45, had had a leg amputated for gross stenosing atheroma of the mouth of the right common iliac artery

Becker found severe atherosclerosis in 26% of the patients aged over 45, but only in 0 4% of the whole series was atherosclerosis a cause of death Although the figure of 0 4% is drawn from patients over and under 45, there remains a significant discrepancy between his two figures which we cannot explain There was no such discrepancy in our series

It seems that our figures for the prevalence of aortic atherosclerosis agree fairly closely with those of Becker who says that " in Bantu subjects the incidence of atheroma of the aorta in the ascending period of life (up to age 45 years) is not far removed from that in other races, and that the incidence of the senescent type may be only slightly less "

Cerebral Vascular Disease

We have already given details of the prevalence of cerebral vascular lesions at necropsy For comparison of findings in Bantu with findings in South African Europeans, it is essential to consider also those Bantu patients in whom it appeared reasonable to assume a vascular catastrophe but who did not come to necropsy or who did not die In this second group, every effort has been made to exclude other diseases capable of causing hemiplegia, and we have excluded all patients with syphilis or diabetes or with abnormalities of the cerebrospinal fluid (except blood) In addition, in an attempt to exclude rupture of a congenital aneurysm, we have excluded all patients below the age of 50 It is conceivable that our criteria have been made over-severe

Within the above limits we found another 37 patients (in 5700 medical admissions) who almost certainly had cerebral catastrophes from atherosclerosis (table III)

In the 21 hypertensive patients, the pressures were

Diastolic pressure (mm Hg)	*Men*	*Women*
90–110	3	2
111–130	4	7
131–150	1	1
Over 150		3
Total	8	13

The combined figures give a grand total of 68 patients admitted for cerebral vascular catastrophes, when correction is made for the limiting age-groups this figure represents 1 5% of all adult medical admissions at risk This is two-thirds of the prevalence of cerebral vascular lesions found in patients admitted to Pietermaritzburg European Hospital (L Fernley, personal communication) But it is probably much below the true prevalence

South Africa is a country of great distances, and no death certificate is required for Bantu dying of natural causes, the patients with cerebral vascular catastrophes who reach hospital represent only that small proportion who are within easy reach of medical help At present there is no method of assessing the numbers who develop hemiplegia and who are buried without record Patients usually come to hospital by bus, this is harder for the paralysed than for other patients

TABLE III—CEREBRAL CATASTROPHES IN PATIENTS AGED OVER 50 (EXCLUDING 31 NECROPSY PATIENTS)

Age-group	*Total*	No with hyper-tension	*Men*	No with hyper-tension	Women	No with hyper-tension
50–54	8	8	6	6	2	2
55–64	9	4	4		5	4
Over 64	20	9	8	2	12	7
Totals	37	21	18	8	19	13

From our findings and those of Becker (1946), we think there is enough evidence to refute the view that the Bantu enjoy any relative freedom from atherosclerosis or from its cerebral complications One interesting finding which needs consideration is the high prevalence of atherosclerosis and its cerebral complications in Bantu women —contrary to the findings in people of European descent (*British Medical Journal* 1955)

Summary

The prevalence of atherosclerosis of the aorta in necropsy examinations in 300 adult South African Bantu shows that aortic atherosclerosis is relatively common in this race 31 patients were found at necropsy to have cerebral hæmorrhage or thrombosis Out of 5700 medical admissions, there were 37 patients in whom the same diagnosis was made but who did not come to necropsy

THE DOCTOR'S ATTITUDE TO HIS PATIENT

MAX B CLYNE
M D Leipzig
GENERAL PRACTITIONER, SOUTHALL, MIDDLESEX

Homo sum, humani nil a me alienum puto —*Terence*

As soon as we have left the haven of medical school and textbooks and entered practice, we learn to our bewilderment that there is more in treatment than drugs, diets, and surgery Some patients will not improve with correct treatment, others will get better on the wrong treatment, some come to us with deep gratitude when we know we have done nothing for them, while others are full of resentment though we have spent much effort and sympathy Such imponderables as the patient's expectations and fears, the doctor's approach and attitude, and the manner of examination not only influence but often outweigh the conventional treatments indeed, as Balint (1957) has shown

The doctor's personality (or " bedside manner ") is accepted as playing a part in treatment, but is usually thought to be incidental, outside the scope of scientific inquiry

Yet people choose or reject a doctor less for his erudition (which they can hardly judge) than for his " personality ", for that peculiar set of qualities that apparently make medicine an art Patients and doctors alike, for successful treatment, somehow have to suit each other If the doctor's personality and attitudes play a part in medical treatment, then they must be worthy of investigation and evaluation Here I propose to do this, using an illustrative case of the doctor's attitude to the call. Why was the call resented, and whence was the hostility derived?

In his previous dealing with the family the doctor had not minded obliging the child's mother. This time, however, he hesitated. The parents clearly thought that the child had acute appendicitis, and the doctor, too, had provisionally made that diagnosis. Considering the mother's previous reaction to the child's tonsillar illness, it seemed fair to assume that she would again demand operation. The doctor did not like this at all. He hesitated to send the child to hospital, as he might reasonably have done, and preferred a more tedious procedure. The doctor's dislike was directed against the possibility of an abdominal operation in this case.

We can see here a further outcome of his identification with the sick child. His dislike of falling in with the mother's presumed wishes was due to his own then unremembered childhood fears of death and mutilation which aroused anxiety. The doctor's hostility was, at least partly, a defence against this anxiety. The hostility was deviated into a well-rationalised delay.

Hostility always has a definite direction. The two persons, or rather images, against which the doctor's hostility was directed, were the child and her mother. The doctor resented the implicit demand by the mother for an operation—a demand which became explicit later. The limit of his willingness to oblige had been reached, and he said, "Let the mother remain anxious."

The action of delay showed also a hidden hostility towards the sick child, because in waiting there was a risk that the child might get worse. We know that the image of the sick child in the doctor arose out of his identification of the child with his own infantile self. The punitive action against the sick child was equivalent to the punishment he expected, as a child, during attacks of pain. The aggressive forces that had been directed against himself were now directed against the image of the child.

We see now one part of the doctor's mental structure which wanted him to do his duty (namely to go) battling against another part, which wanted him to delay. The result was a compromise, which worked fairly well: the doctor had time to deal with his anxiety, he found an outlet for his resentment by delaying, he could alleviate his feeling of guilt by his snap advice, and the child's pain was relieved and the parents' anxiety lessened. We flatter ourselves by calling such a fortuitous confluence of circumstances good clinical judgment.

Guilt

The feeling of guilt might seem peculiar to our case, because the doctor happened to have had certain guilt-laden events in his childhood. But the guilt was not derived only from the doctor's childhood memories. Like most psychic events, it had multiple sources. The doctor's initial anxiety mobilised hostility, or resentment, which in turn mobilised guilt. But even had there been no resentment, we should have found in our doctor the urge to do something for the child and the parents, arising out of the feeling of "concern", which contains an element of threat. The concern about the patient implies a feeling that not to attend to the patient's need might endanger the doctor—either in his self-esteem or in his relationship to the patient—and this feeling is guilt.

The mobilisation of guilt in doctors by their patients is a general and essential spring of their professional activities. The super-ego function which we call professional conscience or a sense of professional duty is based on the sense of guilt, as is all social conscience. The safeguard against default is not the threat of punishment by external agencies, but the internal threat to our self-esteem. This threat, the expression of the conflict between what we ought to do and what we want to do, is, affectively, guilt. Without it, no doctor-patient relationship in our sense would be possible. If identification is the basis of the adaptation of the doctor in the doctor-patient relationship, guilt is the affective driving force.

It is important for the doctor to become aware of, and to be able to accept, guilt. Even the particular arousal of guilt (as in our case) which represents special pleading is common enough to cause irrational treatment of the patient and unnecessary suffering to the doctor. Some doctors cannot do enough for their patients (not always to the patients' advantage), and wear themselves out for trifles, others even committed suicide because they thought they had not done an operation skilfully enough, expiating unconscious guilt and paying far too high a price.

Our doctor felt that something ought to be done to keep the parents occupied, so he kept them busy with the hot-water bottle. In terms of affects, he felt that they were not doing enough for the child. In keeping them actively employed, he reassured not only them but also their image in his own mind, and, having identified himself with them, he reassured himself. The doctor felt the urge to make them into "better" parents, and thus, by identification, became "better" himself.

This urge to produce "good" images of our patients, and thus a "good" self by identification, may lead to therapeutic overactivity which may be disastrous. The urge for the doctor to be a "good" doctor may make it hard for him to bear that at times he cannot cure a patient, and the hapless patient who will not or cannot get better may be mercilessly punished with drugs, operations, and specialist consultations, and eventually perhaps abandoned altogether. There is an element of such compulsion towards "goodness" in the spot advice in our case, too.

The Clinical Examination

When I arrived at the house I obtained a brief history, I then examined the child systematically, beginning with the throat and ears, and including the chest, nervous system, and abdomen, and taking her temperature and pulse-rate. On reflection later, however, I realised that I had examined the throat, ears, nervous system, and chest rather perfunctorily, but the abdomen minutely, including rectal examination.

In busy general practice one cannot always make detailed general examinations, but when I do so, I take pleasure and pride, as most doctors do, in the skill with which I can perform the various diagnostic procedures, and I am thrilled when I discover an unusual sign which shows that I still possess the technical skill that medical education and experience have taught me. But now I had certainly not used my skill to its best advantage. I inspected, percussed, and auscultated the child's chest, but did not find the abnormal signs which two hours later—when the pædiatrician had demonstrated them to me—were fairly obvious. It seems that my examination was made as if it was meant merely to confirm the already settled diagnosis of acute appendicitis. I was apparently searching for confirmatory evidence, turning a blind eye on such signs as might have indicated a different diagnosis.

Yet, I could not accept the diagnosis of acute appendicitis, though I could think of no other. No doubt the mutilation anxiety was one factor that held me back from accepting the diagnosis, with its consequence of operation. But had this been the only reason, then careful and observant examination of the child would have given me enough clues to pronounce joyfully a different diagnosis, and I should have probed for signs of pneumonia rather than overlooked them.

The doctor's attitude was ambivalent: he wanted to find the source of the child's illness in her abdomen, as in his infant days the source of his pain had been presumed to be in his abdomen, yet he did not want it to be there, on account of his mutilation anxieties. His affectively determined conviction make much difference One may therefore conclude that the anxiety, hostility, and guilt already existed within the doctor, and were waiting only for a particular confluence of events to stir them up, apparently the father's story had all the elements of such a confluence

When, afterwards, I thought about the powerful urge for immediate action, I remembered that in my childhood I had had attacks of abdominal pain, supposed to be caused by "wind," which were relieved by the application of heat They frightened me very much I feared that I might die in one, and that the pain and threat of death were punishment for my misdeeds (mainly truancy from scripture lessons and forbidden sexual fantasies) The father's story struck a chord within me and, though the memories of my own childhood suffering were not then brought into consciousness, some of the affects bound up with them—namely, anxiety and guilt—were re-experienced They gave the impetus to my urge for immediate action, and were the driving force behind the swift, almost automatic advice

Transfer of Emotions

Is this merely an anecdotal incident in a doctor's life? Or is our particular doctor perhaps always driven by such emotional urges and conflicting wishes? Or are more fundamental principles involved?

These affects (anxiety, hostility, and guilt) are not particular to our case or even to our doctor The patient always becomes dependent on the doctor who stirs up emotions in the patient which show up in the patient's behaviour But emotions are not transferred in one direction only The doctor's emotions, too, are stirred up by the patient, and far from being the unconcerned observer, he is indeed a partner in an emotional play and counterplay The doctor may like or dislike the patient, approve of or be disgusted with his story, feel that he ought to fob him off with a tonic or investigate his case in detail, be interested in or bored with him All this is usually, as we know on reflection, irrational It remains to be seen whether the particular effects that we discovered in our doctor were specific to him only or otherwise It is perhaps easiest to show that all doctors feel anxiety about their patients On the instinctual level the mainspring that causes doctors to treat their patients is concern—be it about the patient or the doctor's self-esteem—and concern is closely linked to (and perhaps identical with) anxiety This normal and basic effect is aroused whenever instinctual tension rises, whenever something has to be done

We know from our case-history that there had been a previous relationship between doctor and patients, with certain transference and counter-transference patterns When the father telephoned, the doctor formed a mental image of the sick child, based on these patterns All the facts that the father gave were that the child had vomited and was feverish and in pain, but the image which the doctor formed was of a child frightened by abdominal pain and urging relief, very much like the image of the sick child he had been himself, and this similarity made the doctor feel anxious, hostile, and guilty

The image did not exactly correspond to the real sick child, the doctor at the time had *only two* facts at his disposal, the feverishness and the pain The child's fright, her demand for relief, the similarity of her emotions with those of the doctor as a child were all assumed by the doctor Such distortions of the image of a person we are in contact with are common We need only think of the image a lover forms of his beloved, which to the outsider is often quite unrealistic and fanciful A highly distorted patient image will not easily lend itself to a diagnostic appreciation which would be usefully applicable to the real patient Projection of our past and present emotions on to the image of the patient will influence treatment decisions, and gross distortions of the patient-image may lead to technical errors

Identification

The formation of the object-image—in our case the creation of the image of the sick child in the doctor's childhood image—was the outcome of the doctor's unconscious effort to understand the patient in terms of the life experiences of both himself and the patient He identified the object-image with his own image There were further interlinked identification processes going on at the same time The doctor had gone through periods of anxiety at the illnesses of his own child and could identify himself with the parents All these identifications were part of the process of "understanding" the patient-group

Understanding of the patient means identification with him, and thus identification forms the basis of the doctor patient relationship It is normal and necessary for the doctor to identify with his patient and to show anxiety or concern There are, however, certain dangers

The distortion of the patient-image depends on the extent of identification the greater the identification, the more distorted the image If the extent of identification is not controlled, the image may bear little relationship to the real patient Over-identification may lead to such dangerous assumptions as that what is right for us must be right for others It is probably one of the least successful approaches for the doctor to say to his patient "I have a pain in my back, too, and I put up with it!" In our particular case, the identification of the doctor with the child, the distortion of the patient-image, led to a first-aid treatment of controversial value and not based *on rational or scientific considerations*

In an applied science such as medicine, emotional bias and snap decisions cannot be avoided It is important, though, to remember the existence of bias, distortion of the *patient-image*, and excess identification, so long as we recognise them and do not become too defensive or feel too guilty, they will remain natural deficiencies in our tools, which should not greatly impair the quality of our work It would *help* our understanding of our patients and our relationship with them if we could bring into awareness and control that part of the *identification process concerned with image-formation* But the formation of a distorted object-image and the concurrent identification with it are part of our mental defences, and their laying open is unpleasant and often impossible

It is, however, possible, by a study of the routine snap decisions one makes in medical practice, to obtain at least a dim awareness of one's identification processes, and to beware of such snap decisions

The Delay

Having given the snap advice, the doctor then delayed his departure for an hour or so The reasons were perfectly valid medical practice has to be organised in a business-like way in the interest of doctor and patient alike, a reasonable economy in time and petrol, compatible with the interests of the patient, has to be exercised, and an hour's delay in a case of acute appendicitis is no longer very serious

Yet the call was urgent and aroused enough anxiety in the doctor to cause him to advise first-aid treatment Furthermore, calls at inconvenient hours are common, and I have often gone without delay to urgent calls The above reasons cannot, therefore, be complete

We have seen that the emotional situation which led to the snap advice was complex The snap advice over the telephone not only relieved the doctor's anxiety, but also served as a psychic defence against guilt and enabled him to eat his breakfast in peace The snap advice and the delay in going represent the ambivalence

UTERINE IRRITABILITY

HE CONCEPT AND ITS CLINICAL APPLICATIONS, XEMPLIFIED BY THE OXYTOCIN-SENSITIVITY TEST*

C N SMYTH
M A , B M Oxon , B Sc Lond , M I E E
UFFIELD RESEARCH ASSISTANT, OBSTETRIC UNIT, UNIVERSITY COLLEGE HOSPITAL, LONDON W C 1

THE uterus can be stimulated to contract in many ays

Vaginal palpation, dilatation of the cervical canal, or the ntroduction of foreign bodies into the uterus induce contracions or modify the spontaneous rhythm Electrical stimulation f the myometrium or of the cervix will cause local and someimes general contractions Intrauterine infection is said to nitiate contractions Oxytocin, ergometrine, and other xytocic drugs increase the frequency of contractions, while drenaline, papaverine, ether and chloroform anæsthesia, and mylnitrite reduce it Emotional stimuli—such as showing a ypodermic needle to a patient—may excite a contraction he same stimulus in a patient having regular contractions nay cause a contraction to be missed Stimulation of the upples is also known to produce uterine contractions

The magnitude of the stimuli required to elicit a hange in myometrial activity and the response of the terus to a given stimulus are both very variable quanities

The obstetrician wishes to know the overall state of terine irritability Will his patient abort spontaneously?

* 1 had oxytocin also
† 2 had oxytocin for four days

Is labour imminent? Will amniotomy or an oxytocic induce labour? To answer him adequately, the causal factors ought to be assayed separately and their composite effect should then be integrated by some master mind Fortunately, however, the patient is a ready-made laboratory and calculating machine which will do the assay and summation and provide the answer directly Since treatments are aimed at increasing or reducing activity, the responsiveness of the uterus to them can be measured by adding or subtracting a known stimulus of the magnitude required to evoke or suppress activity As uterine irritability may vary spontaneously in a matter of hours, a quick test of irritability is more useful than a lengthy assay

This is not to question the need for further research on the prime causes of myometrial hypoactivity or hyperactivity It is always satisfactory to treat disorders by restoring normal levels of constituents where these can be shown to be in excess or deficient, provided that the abnormal levels found by analysis are prime causes and not compensatory changes But the present inadequacy of this approach is evident from the ineffectiveness of substitution therapy as contrasted with the effectiveness of oxytocic therapy and treatment through correction of mechanical factors

There are many ways in which an overall test of uterine irritability could be performed, and we cannot assume that all would give the same or comparable answers (Stimuli which act on the uterus through the mediation of the nervous system or an intermediate endocrine reaction could hardly be expected to bear a constant relation to those that act directly on the myometrium) Two possible methods are

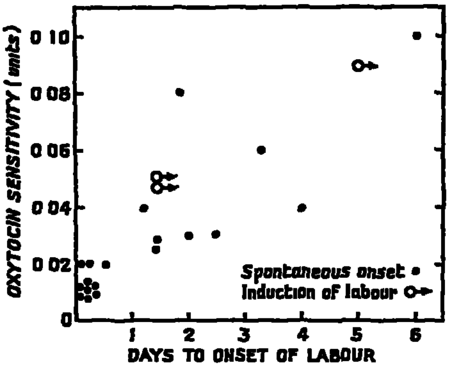

Fig 1—Relation between oxytocin sensitivity and spontaneous onset of labour

Arrowed circles indicate patients in whom the onset of labour was induced artificially This graph, the first evidence of the practical usefulness of the test, was exhibited at the International Congress of Obstetricians and Gynæcologists at Geneva in July, 1954

1 Direct electrical stimulation of the cervix or fundus of the uterus to evoke a local contraction of the myometrium This contraction, however, may not spread to the whole uterus, and is difficult to observe

2 Intravenous administration of minimal doses of oxytocin, 0 01 to 0 1 unit, to cause an increase of uterine activity of observable magnitude In cases of excess activity a reverse measurement can be made by giving minute doses of lævo-adrenaline, which is a potent inhibitor of uterine action

The oxytocin method of assaying irritability is closely enough related to the natural contractile mechanism to be of real value as a clinical sign. Our investigations relating oxytocin sensitivity to the onset of spontaneous contractions, and to the success of methods used to induce labour, support the view that the inert uterus is not myasthenic but merely unable to contract as a whole The reason why it cannot contract as a whole is that the

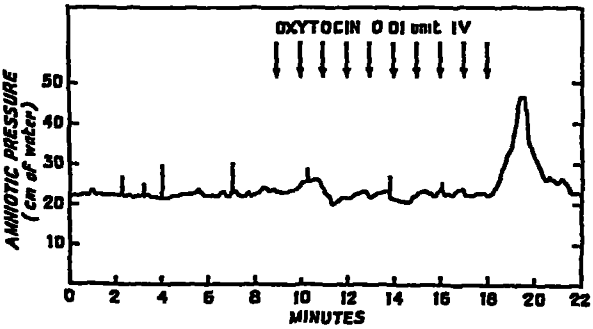

Fig 2—Tocograph recording from patient without spontaneous contractions and with oxytocin sensitivity 0·10 unit.

* Substance of a lecture and discussion given at Symposion über Wehenphysiologie und Pathologie held by the Mittelrheinische Gesellschaft at Marburg in May, 1957

that the illness was in the abdomen overshadowed his contrary wish, and made him overlook the other diagnostic signs But in spite of this there was doubt, and a desire to achieve a correct diagnosis The signs which he became aware of later, with the pædiatrician, must have been perceived and noted, though unconsciously This was enough in a man with medical training and experience to prevent him from declaring bluntly that this was acute appendicitis The perceptive part of his mental apparatus, his ego, was largely occupied with the building of defences against his anxiety, and only a part of the ego was free to deal objectively with reality

Such a reduction of the ego and narrowing of the sense of reality will happen in the countertransference when unconscious affects are mobilised in the doctor to which he must adapt himself by psychic defences Blind spots will then impair some of his ability to perceive or connect logically A knowledge of one's own sources of anxiety would, of course, help one to recognise the blind spots, or, failing that, a second opinion may help to rectify one's errors It is important to remember that diagnostic and therapeutic errors may arise not only through the limitations of one's knowledge or technique, but also, perhaps largely, through affective impairments of one's perceptive and reasoning ability

Choice of Consultant

My inability to arrive at a firm diagnosis added further to my anxiety Of course, I often have to act therapeutically on an uncertain diagnosis, but in this case it seemed important not to do so I had to be a "good" physician, one who can diagnose and heal

Sometimes we find it easier and sometimes harder to admit medical defeat, or, in terms of the counter-transference, sometimes we can bear to be "bad" and sometimes we cannot I had identified myself with a child who was ill or, in terms of my infantile fantasies, "bad" I had identified myself with the parents too, and the load of guilt in having to be both a "bad" child and a "bad" parental figure would have been too much Previously I transformed the parents into "actively good" parents, for the relief of guilt Similarly, I had to transform myself into an "actively good" doctor

There was only one way of doing so—by calling in a consultant on whose opinion I could rely Psychologically speaking, I was searching for another "good" doctor with whom I could identify myself and thus, by the process of identification, become a "good" doctor myself I put the alternative of hospital or domiciliary consultation before the patient-group but, in fact, the decision had already been taken I knew that the child did not want to go into hospital, and I trusted myself to persuade the mother to my decision

The pædiatrician came I agreed with the consultant on the points he raised, and felt much relieved Anxiety and guilt left me on identification with the consultant It was, after all, not the child's abdomen that was the seat of the trouble, there was no question of operation, and my doubts about the diagnosis had proved that I was a "good" doctor

Why did the doctor call a pædiatrician and not a surgeon into consultation? After all, acute appendicitis was the nearest approach to a diagnosis, and the proper person to consult would have been a surgeon But the doctor tried, even in the selection of his consultant, to fight shy of a diagnosis that might involve operation His infantile mutilation anxieties determined the choice of consultant Again, this affect-determined choice is not restricted to the case under discussion Many patients with hysterical conversions symptoms are sent to cardiologists, neurologists, and surgeons, sometimes with and sometimes without the rationalisation of "to exclude organic disease", but always in the fervent hope that the doctor may be spared the anxiety-arousing, upsetting recognition of emotional tempests in the patient, which in turn, in the counter-transference, stir up the doctor's emotions

The Penicillin Injection

The final step was the injection of penicillin The pædiatrician had advised antibiotics without specifying them It is my habit to use oral antibiotics in children to avoid the hurt of injection ' But now I felt *differently*, I thought of penicillin as a specific for pneumonia, of the saving in the national drug bill, and of the quicker action of parenteral administration, and I felt suddenly very righteous about giving injections

Looking at the case as a whole, the question of operations and maiming has been prominent We remember that the character of my relationship with the patient-group had been determined by my compliance with the mother's wish for tonsillectomy An operation, beneficial as it may be, is mutilating The doctor was used by the mother as an instrument for this symbolically destructive action When he complied, she was very pleased with him and thereby made him feel that he was a "good" doctor The same happened in the case of the appendix The mother hoped, and even pressed, for the relief of her anxiety over the sick child again through attack on the bodily integrity of the child, and again the doctor was to be the instrument Now, however, the doctor could not agree, because this aroused his own mutilation anxieties But he had hostile feelings of his own towards the child, connected with his infantile self-punitive desires

This aggression was successfully repressed until the final act, the injection, when the child could be hurt, yet where the action could be freed from all guilt, as the doctor's rationalisation has shown In fact, the deep justification felt by the doctor for the injection was a form of over-compensation, a way of saying "Not only have I done no wrong, I have done very much right"

The doctor liked his little patient, and wanted to help her and make her well, but through *identification he felt* hostile and unconsciously wanted to hurt her We can often discover aggressive and hostile slants in our treatment activities evil-tasting medicines, reproaches, coldness, excessive brevity, refusals, operations We usually have very good excuses, but the emotional background is one of hostility In our case, the unconscious emotions of liking and wanting to hurt were the expression of two basic drives directed towards the patient—affection and aggression—which had been in conflict Affection had led to identification, willingness to help, concern, anxiety Aggression had led to hostility, delay, guilt Now, they had become fused This fusion was expressed in the helping, yet hurting, act of the penicillin injection

The final act illustrates well the fundamental source of the affects, especially anxiety, which we have studied previously The conflict between libido and aggression, brought about tension, which was felt as anxiety Various other tension-raising and anxiety-producing psychic events in turn happened, as we have seen, and increased the basic anxiety

Summary

In an ordinary illness, a case of pneumonia, the influence of the attitudes of the doctor on diagnosis and treatment have been studied The attitudes are based on the identifications of the doctor with the patient and his family, and the underlying emotional driving forces in the doctor-patient relationship are anxiety, hostility, and guilt They may be used in the service of the patient, or to his detriment, because they may blind the sense of reality in the doctor, unless he is aware of them and their sources

I wish to thank *Mr John O Wisdom*, PH D, and *Dr M Balint* for helpful criticisms of my manuscript

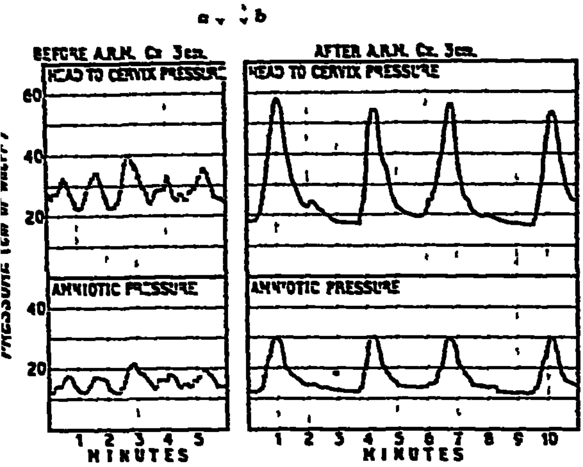

Fig 7—Direct irritating effect of amniotomy resulting from increased pressure on cervix a, before rupture of membranes, b, after rupture of membranes. Cervix 3 cm dilated. There was an interval of only 3 minutes between a and b

est for about an hour The patient is assured that the investigaion is painless and harmless and will aid her treatment

Some form of contraction recorder is placed on the abdomen tocograph) and a recording made for a quarter of an hour or more to note any spontaneous contractions Oxytocin 0 01 unit per ml is prepared in a 10 ml syringe, and the injection is begun at the end of a spontaneous contraction or of any spurious contraction elicited by the exhibition of the syringe. An arm vein is chosen, and care must be exercised to ensure that the patient's clothes do not occlude the venous return The patient is asked to close her hand from time to time during the injections to prevent venous stasis in the arm 0 01 unit is injected at minute intervals until a contraction occurs The total dose given is called the oxytocin sensitivity

The intensity of the contraction elicited can be noted and is often found to be much stronger than the spontaneous contractions which preceded the test. This shows the capabilities of the myometrium and that the spontaneous contractions were not exciting the whole uterus

In some patients with a fast spontaneous contractile rhythm, perhaps one or more weak contractions per minute, a condition called by Alvarez and Caldeyro-Barcia (1954) uterine fibrillation, the test organises this activity into a generalised contraction of normal strength, but in a few patients oxytocin only accentuates the fast rhythm The proper treatment of patients in this latter category has not been determined

The result of the investigations into the value of the test are shown by figs 1–7

Investigations, not reproduced graphically, showed that there was no significant relation between results of the test and the length of labour This was to be expected because the irritability is related to the onset of labour and not to the difficulties to be overcome Further, no significant relation was found between the interval from induction to the onset of labour and the extent to which the cervix is taken up at the time of induction Examination of the cervix did not appear to be a satisfactory alternative to the oxytocin-sensitivity test.

Summary

The biological irritability of the uterus can be assessed by measuring the minimal dose of oxytocin required to produce a perceptible change in myometrial activity The magnitude of dose required is used to specify the irritability

This oxytocin-sensitivity test has useful clinical applications When labour is induced surgically, the results of the test bear a significant relation to the interval between amniotomy and the onset of labour They are also related to the rate of oxytocin infusion required to establish regular labour-like contractions

In normal patients near term, the test indicates how long an interval may be expected before the spontaneous onset of labour If the test shows a constantly low uterine irritability day after day, the infant is likely to be postmature unless labour is induced

Other tests on the same principle are possible but have not been investigated.

The test has applications to the study of uterine action because it provides a method of measuring the change in irritability resulting from administration of drugs or from the application of other stimuli to the myometrium or its nerve-supply

This work was undertaken as part of a programme of obstetric research supported by the Nuffield Foundation and the Rockefeller Fund of University College Hospital Medical School In addition the support and encouragement of Prof W C. W Nixon and the staff of the obstetric unit is gratefully acknowledged.

BLOOD-GROUPS IN TUMOURS OF SALIVARY TISSUE

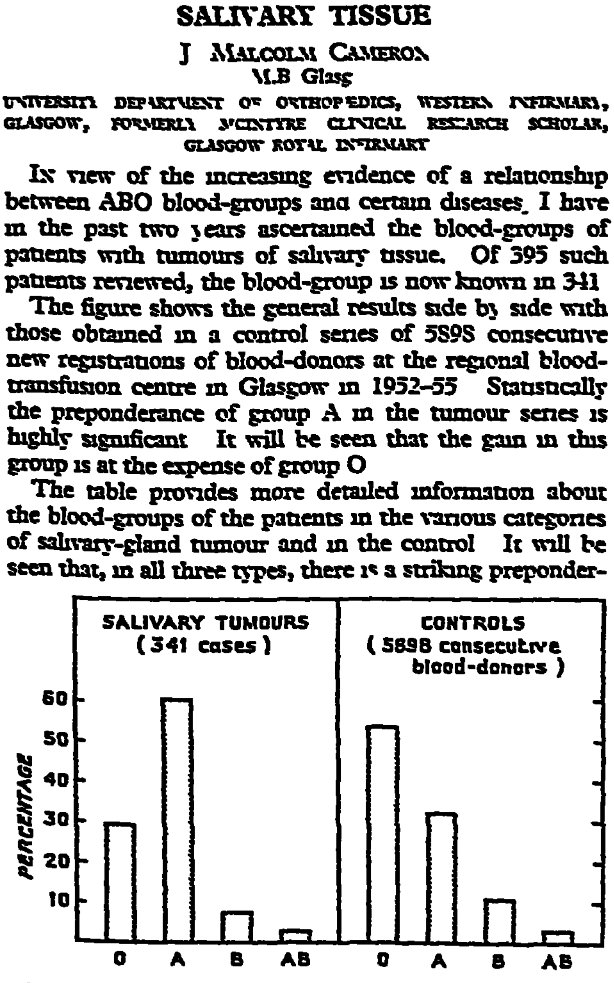
J MALCOLM CAMERON
M.B Glasg

UNIVERSITY DEPARTMENT OF ORTHOPAEDICS, WESTERN INFIRMARY, GLASGOW, FORMERLY M'CINTYRE CLINICAL RESEARCH SCHOLAR, GLASGOW ROYAL INFIRMARY

IN view of the increasing evidence of a relationship between ABO blood-groups and certain diseases, I have in the past two years ascertained the blood-groups of patients with tumours of salivary tissue. Of 395 such patients reviewed, the blood-group is now known in 341

The figure shows the general results side by side with those obtained in a control series of 5898 consecutive new registrations of blood-donors at the regional blood-transfusion centre in Glasgow in 1952–55 Statistically the preponderance of group A in the tumour series is highly significant It will be seen that the gain in this group is at the expense of group O

The table provides more detailed information about the blood-groups of the patients in the various categories of salivary-gland tumour and in the control It will be seen that, in all three types, there is a striking preponder-



Distribution of blood-groups in 341 patients with tumours of salivary tissue and in 5898 controls

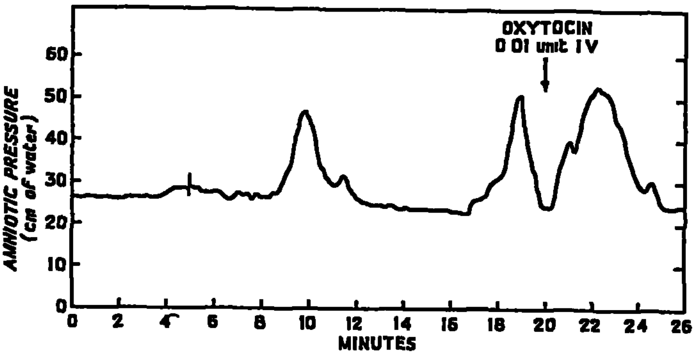


Fig 3—Tocograph recording from patient with spontaneous contraction every 9 minutes and oxytocin sensitivity 0 01 unit

conduction mechanism by which a local contraction spreads to the whole organ is inactive (Csapo 1955, Jung 1956)

Clinical Value of Assessing Irritability

When irritability is considerable, labour is usually imminent, when irritability is less, a longer time will probably elapse before labour begins spontaneously This differentiation enables patients to be kept in hospital or to be sent home When a woman has mild toxæmia or is past term, measurement of uterine irritability helps the clinician to decide whether to induce labour or await its onset When delivery is urgent, labour will be induced in any event, and then the test enables a decision to be made between oxytocin therapy and amniotomy, or possibly a cæsarean section if the uterus is non-irritable and speedy delivery is required Patients with a delayed onset of labour will often be found to maintain the same degree of reduced irritability day after day, as though they had reached the ceiling of their endocrine or other capabilities

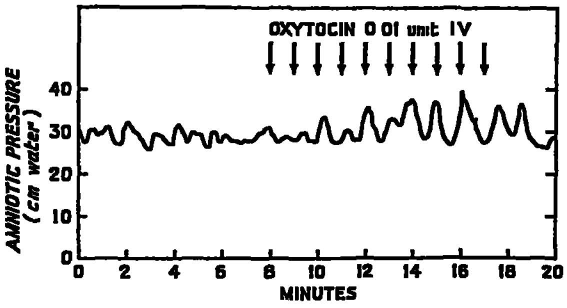

Fig 4—Ineffectiveness of oxytocin in uterine fibrillation.

Methods of inducing labour act because they are biological irritants With the exception of oxytocic drugs, they are weak irritants and therefore ineffective unless the uterus has an irritability approaching that required for spontaneous labour

Amniotomy, which not only acts as an irritant but is also an aid to shorter labour, is undoubtedly the best means of induction, provided the uterus is irritable enough to respond

Rupture of the fore membranes allows the presenting part to descend and, by increasing pressure on the cervix, directly stimulates uterine action (Huber and Beck 1957) Reduction of uterine volume makes the muscle-fibres shorter, and they may thereby become more active physiologically, this effect is principally noticeable in the presence of hydramnios Trauma of the cervix may contribute to irritability chemically or through the nervous organisation Low, opposed to high, rupture of membranes owes its superior effectiveness to the first of these factors

The table and figures show that amniotomy is very successful when the oxytocin test has a numerical value of 0 04 unit or less, and is progressively less successful as the sensitivity approaches 0 08 unit The correlation between the oxytocin sensitivity and the time from amniotomy to th onset of labour is significant at a probability of 200 to

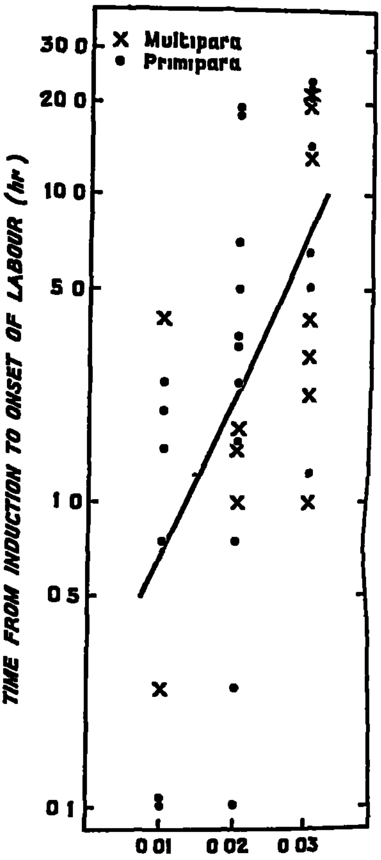

Fig 5—Relation between oxytocin sensitivity and onset of labour after amniotomy of fore membranes in patients more sensitive than 0 04 unit The correlation is significant at 200 1 probability

BLOOD-GROUPS IN TUMOURS OF SALIVARY TISSUE

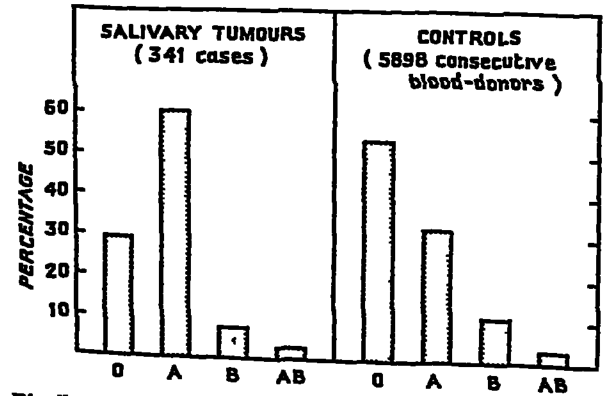
J MALCOLM CAMERON
M B Glasg.

UNIVERSITY DEPARTMENT OF ORTHOPÆDICS, WESTERN INFIRMARY, GLASGOW, FORMERLY MCINTYRE CLINICAL RESEARCH SCHOLAR, GLASGOW ROYAL INFIRMARY

IN view of the increasing evidence of a relationship between ABO blood-groups and certain diseases, I have in the past two years ascertained the blood-groups of patients with tumours of salivary tissue Of 395 such patients reviewed, the blood-group is now known in 341

The figure shows the general results side by side with those obtained in a control series of 5898 consecutive new registrations of blood-donors at the regional blood-transfusion centre in Glasgow in 1952–55 Statistically the preponderance of group A in the tumour series is highly significant It will be seen that the gain in this group is at the expense of group O

The table provides more detailed information about the blood-groups of the patients in the various categories of salivary-gland tumour and in the control It will be seen that, in all three types, there is a striking preponder-



Distribution of blood-groups in 341 patients with tumours of salivary tissue and in 5898 controls.

INCIDENCE OF DIFFERENT TYPES OF TUMOURS OF SALIVARY TISSUE ACCORDING TO BLOOD-GROUPS

Blood-group	Control	Pleomorphic adenoma	Carcinoma	Adeno-lymphoma	Total
A	1906 (*32 3%*)	170 (*57 8%*)	29 (*82 9%*)	7 (*58 3%*)	206 (*60 4%*)
B	637 (*10 8%*)	23 (*7 8%*)	1 (*2 8%*)	1 (*8 3%*)	25 (*7 3%*)
O	3177 (*53 9%*)	92 (*31 3%*)	5 (*14 3%*)	3 (*25 0%*)	100 (*29 3%*)
AB	178 (*3 0%*)	9 (*3 1%*)	—	1 (*8 3%*)	10 (*2 9%*)
Total	5898	294	35	12	341

ance of group A and a corresponding rarity of group O compared with the controls

In analysing the figures, as groups B and AB are relatively constant throughout, group O has been compared with groups A, B, and AB combined together, and the results compared with the control as follows

(1) Pleomorphic adenoma ($\chi^2=57\ 3$) shows a highly significant percentage with group O significantly higher for the controls as against pleomorphic adenoma

(2) Carcinoma ($\chi^2=21\ 9$) again shows a highly significant percentage with group O significantly higher for the controls

(3) Adenolymphoma does not show a significantly lower percentage of group O ($\chi^2=2\ 94$) The indications, however, are that, if the number of patients were increased, significance would be established

(4) All types of salivary tumours were finally considered together and, as would be expected, there was a highly significant ($\chi^2=77\ 9$) percentage, with group O significantly higher for the controls

These findings provide convincing statistical evidence of an unusually high incidence of blood-group A in this series of patients with salivary tumours This is all the more striking because in Scotland group A is found in a smaller proportion of the population than in England

Discussion

From recent investigations into the relationship between disease and ABO blood-groups it appears that these groups are associated with susceptibility to some disorders and relative immunity to others The incidence of group A has been shown to be unduly high in patients with pernicious anæmia (Buchanan and Higley 1921), carcinoma of the stomach (Aird et el 1953), and bronchopneumonia in infancy (Struthers 1951) Group O occurs with excessive frequency in persons with peptic ulceration (Aird et al 1954, Brown et al 1956)

Of these associations the most striking so far published is that between the blood-group and lesions of the stomach and duodenum In the present investigation, however, an even greater excess of group A has been found in patients with tumours of salivary tissue

The selection of a control group presents a well-recognised difficulty (Allan 1954) As a proportion have diseases known to be associated with certain blood-groups, hospital patients are unsuitable I am indebted, therefore, to Dr John Wallace, of the regional blood-transfusion centre in Glasgow, for the data concerning consecutive donor registrations

Summary

The distribution of ABO blood-groups among 341 patients with tumours of salivary tissue was determined The frequency of group A was significantly higher than in 5898 consecutive donors registered at the regional blood-transfusion centre

85 of the patients attended the Western Infirmary and the Southern General Hospital, Glasgow (1950–55), and the others the Glasgow Royal Infirmary (1935–56) I should like to thank the medical superintendents of these three hospitals for access to patients and records, and Mr R A Thomson for considerable help in tracing the Royal Infirmary patients I am indebted to Prof W A Mackey, Prof T Symington, and Dr A Dick for valuable advice and criticism, to Dr I Cook and Dr Robert McAndrew for cross checking most of the blood-groups, to Dr R A Robb, of the department of mathematics in the University of Glasgow, for providing statistical assistance, to Mr P Elliott for the tables, and to all the surgeons and general practitioners who have assisted me throughout the investigations

DISCREPANCIES IN THE DIAGNOSIS OF GENETIC SEX BY LEUCOCYTE MORPHOLOGY

D J B Ashley
M D Lpool
SENIOR REGISTRAR IN PATHOLOGY, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL

C H Jones
M D Lpool
ASSISTANT PATHOLOGIST, ALDER HEY CHILDREN'S HOSPITAL, LIVERPOOL

The development of cytological methods for the diagnosis of genetic sex has been a great stimulus to the study of human intersexuality Two techniques are available

(1) A high proportion of the intermitotic nuclei of the cells of the skin and many other tissues show, in the female, a characteristic mass of heterochromatin usually lying adjacent to the nuclear membrane Such masses are seen in less than 10% of the nuclei in normal males (Moore and Barr 1954)

(2) Davidson and Smith (1954) described the presence of a nuclear appendage or "drumstick" satellite on the nuclei of polymorphonuclear leucocytes In the normal female more than 6, and in the male less than 6, such bodies were found in a count of 500 mature polymorphs

For the sake of brevity the genetic sex determined by the first method will be described here as the nuclear sex, and by the second as the polymorph sex We record two cases in which a discrepancy was found between the results obtained by the two methods, and we discuss the validity of the leucocyte method

Case-reports

Case 1—A child aged 20 months (described in detail by Ashley and Jones 1958) is considered to be an example of complete sex reversal in that the nuclear sex is male but the phenotype is female and the gonads are histologically indistinguishable from normal infantile ovaries Cells from the skin and buccal mucosa were examined on several occasions, and heterochromatin was always found in less than 6% of the resting nuclei Examination of blood-films, however, showed that "drumsticks" were present in 3% of the polymorphs, a frequency well within the range regarded as female

Case 2—This patient, a case of Turner's syndrome, was seen at the age of 14 months because of poor gain in weight She then weighed 16 lb 5 oz, her birthweight having been 6 lb 14 oz She was undersized, with slight webbing of the neck and marked cubitus valgus Her external genitalia were normal Heterochromatin was found in 4% of the cells of her buccal mucosa, and her genetic sex was diagnosed as *male* Examination of blood-films, however, showed "drumsticks" in 7% of the polymorphs

Fig 1—Neutrophil band cell showing mass of sex chromatin (Feulgen × 1500)

Fig 2—Neutrophil polymorph showing mass of sex chromatin. (Feulgen × 1500)

Fig 3—Neutrophil polymorph showing mass of sex chromatin and satellite drumstick" (Feulgen. × 1500)

Discussion

During the past two years many workers have reported discrepant results in the diagnosis of genetic sex by the two methods

Plunkett and Barr (1956) reported two cases of Klinefelter's syndrome in which the nuclear sex was female but the polymorphs had "drumsticks" in only 6 of 784 cells and 6 of 900 cells This frequency of "drumsticks" is just outside the normal range for females Similar discrepancies were seen by Riis et al (1957) in two cases of Klinefelter's syndrome, by Kosenow (1957) in a case of Turner's syndrome of female nuclear sex, by Wiedemann (1957) in cases of Klinefelter's syndrome, and by Armstrong et al (1957) in a case of true hermaphroditism in which the nuclear sex was female

All these discrepancies were in the same direction—i e, the nuclear sex was female, but the polymorphs showed a smaller percentage of satellites than is normal in the female Our two cases show an incongruity in the opposite sense, the nuclear sex being male but the polymorphs showing satellite frequencies well within the female range Greenblatt et al (1957) have reported the same discrepancy in three cases of Turner's syndrome

Such findings as we have mentioned must raise the question of the validity of each method of genetic sexing vis-à-vis the other

Lennox (1956) has reviewed the subject of nuclear sexing and has discussed the evidence supporting the current view that the "sex chromatin" of the resting nucleus is closely associated, if not identical, with the XX-chromosome complex

Davidson and Smith (1954) were tempted to regard the nuclear satellite as analogous to Barr's sex chromatin, which had become pinched off in drumstick form, and thus analogous to the XX-chromosome complex Davidson (1957), however, has reported discrepant findings in Klinefelter's syndrome and now regards the satellite bodies of the leucocytes as being less closely linked to the XX-chromosome complex than is the nuclear heterochromatin

Briggs and Kupperman (1956) carried out polymorph sexing on twenty abnormal males and forty-one abnormal females and described the results in fifteen cases as "not conforming exactly to the criteria of Davidson and Smith but diagnosable" They emphasised this point and suggested that the incidence of "drumsticks" might have been influenced by the abnormal hormonal environment seen in these cases of aberrant sexual development

Some workers however, still regard the polymorph method of sexing as an accurate indication of the genetic sex Kosenow (1956) recommends that it should be used in preference to skin biopsy or mucosal smear, and cases of aberrant sexual development have been recorded in which the genetic sex has been diagnosed only from blood-films

Carpentier et al (1957) found a sex difference in the leucocytes of the rabbit, a species in which the conventional method of nuclear sexing is inapplicable They claimed to find evidence of the subdivision of the "drumstick" in a manner analogous to the "diplococcus form" of the sex-chromatin body of the nerve-cell described by Crouch and Barr (1954) and they regard the "drumstick" in the rabbit as a cytological expression of the XX complex, as do Sachs and Danon (1956) in man Cytological studies of human blood-cells are scanty Riis (1957) found that sex chromatin could be identified in the lymphocytes of the peripheral blood, and Ashley (1957) reported the occurrence of sex chromatin in the resting nuclei of cells of the blood and bone-marrow in man Sex chromatin was identified in each type of cell of the myeloid series, including polymorphs, which showed also the "drumsticks" of Davidson and Smith (1954) It was identified also in lymphocytes and in early and intermediate normoblasts The nucleus of the late normoblast, which is not in an intermitotic phase, shows no sex chromatin Figs 1–3, taken from a specimen of bone-marrow from a normal fecund female, show masses of heterochromatin beneath the nuclear membrane in mature polymorphs and a band cell, one of the former showing also a "drumstick" satellite

The finding of discrepancies between the nuclear sex and the polymorph sex, together with the cytological demonstration in leucocytes of typical sex-chromatin masses distinct from the nuclear satellite, indicates that leucocyte morphology cannot be accepted as a valid criterion for the diagnosis of genetic sex, and that the satellite body of the polymorph should be regarded as a sex characteristic rather than as the expression of the XX-chromosome complex It is likely, however, that the characteristic leucocyte morphology is genetically controlled This view is supported by the finding of female-type polymorphs in the blood of the male twins in two instances of blood chimerism in man (Booth et al 1957, Nicholas et al 1957) In both these cases it was postulated that female myeloid cells had been implanted in the bone-marrow of the male twins, and that they had retained their ability to produce "drumstick" satellites

In conclusion we suggest that the determination of genetic sex, which has now become an important diagnostic tool, should be carried out by the method, and using the criteria, of Moore and Barr (1954) The buccal mucosa affords the simplest method of obtaining suitable cells, but the skin and many other tissues may be used if available Leucocyte morphology, though clearly deserving much further study, particularly where discrepancies occur, cannot be regarded as a satisfactory routine method

Summary

Two cases are described in which the nuclear sex was male but the polymorph sex female

The validity of the hæmatological diagnosis of genetic sex is discussed, and it is concluded that the "drumsticks" of the polymorphonuclear leucocytes should be regarded as a sex characteristic rather than as the XX-chromosome complex, and that for routine diagnostic purposes the nuclear sexing method is to be preferred

We wish to thank Miss I Forshall, F R C S, and Dr R H White-Jones for allowing us to report case 1, Dr A E McCandless for allowing us to report case 2, and Dr E G Hall for helpful discussion and advice

CAVERNOUS HÆMANGIOMA OF THE LUNG

John F Goodall
M D Cantab
GENERAL PRACTITIONER, SKIPTON, YORKS

Ian Stewart
M D Leeds
CONSULTANT PATHOLOGIST, KEIGHLEY HOSPITAL GROUP, YORKS

In a review of the literature Stringer et al (1955) collected 140 published cases of cavernous hæmangioma and added 2 of their own In 135 the ages of the patients when first seen had been recorded

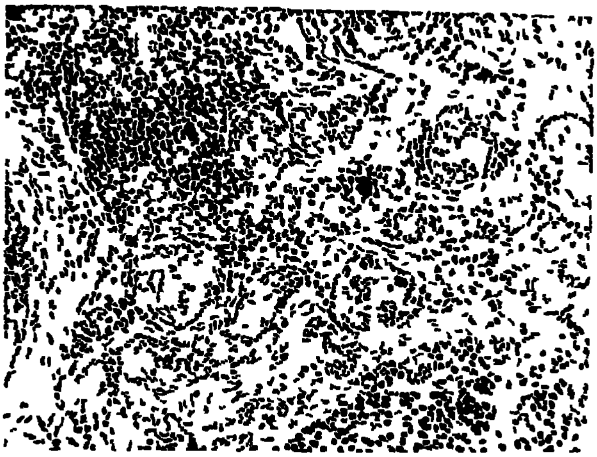
Age	*No of Cases*	*Age*	*No of Cases*
0–7 days	3	31–40 yr	16
7 days–1 yr	3	41–50 yr	19
1–10 yr	11	51–60 yr	15
11–20 yr	23	61–70 yr	4
21–30 yr	40	71–80 yr	1

We report here another case, in a man of 66, which has some unusual features

Case-report

A tall lean shepherd, of 66, complained in 1954 that he had had a cough for many years In 1945 he had coughed up a quantity of blood but had not felt ill and had not sought medical advice In 1949 he had had another hæmoptysis, followed by pyrexia for several days No further attack occurred until 1954, when a bout of hæmoptysis was accompanied by an exacerbation of the cough

No abnormal physical signs were found in the chest The radiologist reported "Hypertensive heart shadow The lung fields show moderate emphysema but no other lesion" It was thought that the hæmoptyses might have been due to epistaxis or to the strain of coughing The patient did not attend at the surgery again, and in 1957 was found dead in bed A coroner's inquiry followed



Cavernous hæmangioma of lung

Necropsy Findings

There were no angiomata on the skin or in the mouth, and there was no clubbing of the fingers Each bronchus contained about 1 oz of liquid blood The one leading to the left lower lobe was a little dilated and its inner surface red and velvety Most of the left lower lobe was red and indurated, and some of the smaller air passages exuded pus On the external surface the affected zone was slightly raised and had a serpiginous margin There was no shrinkage of the lobe as a whole The lung tissue elsewhere showed moderate œdema There was some hypertrophy of the left ventricle (heart 370 g) The coronary arteries were of calcified pipe-stem type, and the descending branch of the left vessel was blocked for about an inch by adherent antemortem thrombus No other significant changes were found

Histology

Bronchus to the left lower lobe—The mucosa was almost fully replaced by a vascular sheet densely infiltrated by plasma cells and lymphocytes, the cells penetrating deeply among the submucosal secretory glands There was no structural arrangement suggesting specific inflammation A smaller air-vessel close by showed the same changes with almost complete blockage

Red zone of the lung—The centre consisted of a cluster of vascular spaces filled with blood and embedded in dense inactive fibrous tissue (see figure) At the periphery relatively normal lung tissue was solidly packed with extravasated blood At the junction of the two zones there was a patchy and fairly dense infiltration by plasma cells There was also a tiny focus of suppuration accompanied by necrosis The lesion was evidently an ancient cavernous angioma, the hæmorrhages from which had led to fibrosis and the migration of chronic inflammatory cells, with a secondary acute infection added

Discussion

Willis (1955) states that hæmangiomata are in practically all cases malformations and not neoplasms They may arise in one particular tissue or as part of a syndrome The tissues which may be affected are the skin, bones, central nervous system, peripheral nerves, and viscera The syndromes are combinations of lesions in the following sites

(1) *Skin and mucosæ*

This hereditary disorder is particularly associated with the name of Osler (1901), who described 3 cases At least four workers had drawn attention to the disease previously *The* essential features are the skin lesions, epistaxis from nasal lesions, and the coincidence in several members of a family Less usually hæmorrhages take place from the trachea, alimentary tract, and urinary tract, and in the brain A detailed survey of 218 families was made by Garland and Anning (1950) and subsequently of a further 20 families

(2) The skin and various viscera
(3) The skin and central nervous system
(4) The retina, central nervous system, and viscera

In the present case there were no angiomatous lesions other than in the lung Until quite recently the solitary hæmangioma of the lung was considered to be very rare

Whitaker (1947) could find only 5 reports and added a further 2 cases Cleland (1948) cited Whittaker's findings and described 1 further case Stringer et al (1955) collected 140 cases and added 2 of their own The first published description is that of Churton (1897), who demonstrated the lungs of a boy, aged 12 years, affected by "multiple aneurysms of the pulmonary artery" The first clinical diagnosis was made by Smith and Horton (1939) and the first successful surgical removal by Hepburn and Dauphinee (1942)

Stringer et al (1955) and other workers call the condition pulmonary arteriovenous fistula The essential disturbance of normal physiology is that the angioma is fed by the pulmonary artery and drained by the pulmonary vein, a shunt being provided for venous blood, which, if large enough, will lead to dyspnœa, cyanosis, finger clubbing, and polycythæmia The last-named may, of course, lead to peripheral thrombosis, cardiac hypertrophy, headache, and so on Hæmoptysis develops in a minority of cases and leads to further difficulty in diagnosis If the lesion is large enough, a loud bruit is discovered over the lesion

In the present case cough and hæmoptysis were the only features The lesion was too small to provide either a serious shunt, an audible bruit, or a lesion visible on radiography The published cases are practically all of grave morbidity in infants in whom the condition was compatible with life for days or weeks, in young persons regarded as the subject of congenital heart-disease, and in adults so incapacitated by defective oxygenation that lobectomy was imperative Whitaker's (1947) case 2, however, a man, aged 33, with lip angiomata, a bruit over the tumour, and worm-like opacities in the lung, was symptom-free when operation was suggested and declined to undergo it

The following details cited from Stringer et al (1955) give some indication of the condition seen in patients aged more than 60

(1) Female, aged 65, disabled by dyspnœa for thirty years, bilateral lesions, no operation

(2) Female, aged 63, with dyspnœa and cyanosis for fifteen years, no operation

(3) Female, aged 66, with pain in the back Discovered at routine radiography, no operation

(4) Female, aged 63, with symptoms since childhood Died at operation

Summary

A man who died of coronary thrombosis, and was known to have had a cough and hæmoptysis without other disturbance, was found to have a small cavernous hæmangioma of the lung

The photograph is by the photographic section of the Royal Society of Medicine

IT has long been known that photic stimulation may precipitate convulsions in persons of epileptic constitution The earliest recorded method was that used by the ancient Greeks when selling slaves in the market (Temkin 1945) The potter's wheel was rotated in front of their eyes In some the intermittent occlusion of the sunlight caused vertigo and occasionally a seizure In recent years this phenomenon has been used as an activator of epileptic discharges in patients undergoing investigation by electroencephalography The source of light is a high-powered stroboscope in which the frequency of the flash can be altered (Walter et al 1946, Gastaut et al 1948, Gastaut and Gastaut 1949) Bickford (1948) studying normal subjects by photic stimulation, noted that in 92% of people the occipital frequencies could be "driven"—that is, the frequencies followed the rate of flashes produced by the stroboscope In many there was an associated subjective sensation of colour which was not unpleasant Abnormal discharges, mainly slow and limited to the occipital region, could be produced in some, and in a few there was evidence of paroxysmal discharge of the whole cortex

It seems remarkable that some epileptics, particularly children, should have discovered these facts by chance, and subsequently should have found themselves compelled to induce epileptic episodes in themselves by producing flickering-light stimulation (Rail and Money 1953, Bickford et al 1953, Robertson 1954) We report two further cases in which epileptic attacks are initiated by self-induced photic stimulation

Clinical Records

Case 1—A girl, aged 7 years, was first referred to one of us (J H H) on June 13, 1956, for an opinion as to the nature and significance of an odd "habit" which her parents had noted with increasing concern This was described as a rapid "flicking" of her left hand, with fingers held wide apart, in front of her eyes She always faced towards the sun to do this and never performed on dull days When she started to "flick", her eyelids blinked synchronously After a few seconds she became motionless and "her eyes go blank as if she was not there" Then she staggered or stumbled On occasions she had fallen down, and once scratched herself severely by falling into a rose-bush The loss of consciousness lasted for only a few seconds, and immediately after the episode "she is back to normal" She induced attacks only with her left hand, though she was naturally right-handed Her parents had never noticed any spontaneous mental lapses The child's "habit" had first been noted about a year previously About that time she had been taken to an ophthalmologist because of a concomitant convergent strabismus For purposes of examination her pupils were dilated with atropine This experience upset her considerably, but unfortunately the parents cannot be sure whether the "habit" started before or after this episode The mother maintained that she could tell if the child had been "flicking" a lot as at these times she was irritable

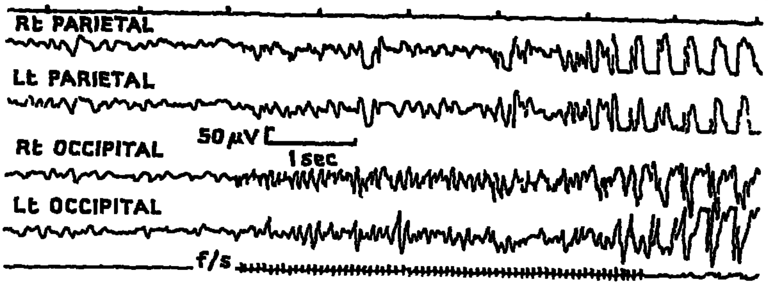

Fig 2—Case 2 Stroboscopic activation at 14–15 flashes a second producing atypical spike and wave which lasted 3–4 seconds

She was an only child Her birth was uncomplicated, and she had had no serious physical illnesses The parents, both very intelligent if fussy people, described her as always having been an excitable and very determined child, who was noisy and overactive and chattered endlessly She ran rather than walked, strove to be the centre of attraction, and had never had any special friends Her only fear was of dogs

There was no family history of epilepsy When the child was 5 months old, her mother had a schizophrenic episode which required 8 months' treatment in a mental hospital, she responded well to insulin therapy and there had been no recurrence From the beginning of this illness a nanny took over the care of the child, continuing until March, 1956—i e , until after the onset of the "hand-waving" The small private school which she attended describes her as impulsive, erratic, and lacking in concentration The staff and her classmates had frequently commented on her "habit" and had made unsuccessful attempts to stop it, as had her parents She once protested to her mother "I just have to do it "

Clinical examination did not reveal any sign of organic disease, she was a big, well-developed girl At the first consultation her general behaviour and demeanour were grossly abnormal She flitted around the consulting-room, apparently ignoring the physician, picked up various objects lying about, and made comments about them without showing any real interest She forced on the onlooker the first impression that here was a spoiled, ill-mannered, and irritating only child

Electroencephalography (E E G) —The resting record was not normal for a girl of her age There was little evidence of a repetitive frequency, but there was a wide range and abnormal bursts of high-voltage spikes, mainly in the occipital region There was no asymmetry (fig 1*a*) Stroboscopic activation at 15–16 flashes a second produced a clear attack of atypical spike and wave lasting for 2–3 seconds (fig 1*b*) Activation at 3 flashes a second had no such effect

Psychological testing showed her to be of superior average intelligence During the test she was tense, distractable, and easily startled by noises On visuomotor tests (Bender-Gestalt) some spatial disturbance was revealed by the transposition of the designs from the horizontal to the vertical Projective tests (thematic apperception and children's apperception tests) showed good general orientation, and no evidence of psychotic trends Her responses gave the impression of a child living in an emotionally cold world The Rorschach test revealed strong compulsive tendencies, and there was a suggestion that her intellectual performance was not up to her capacity Her behaviour in the initial play-interviews was succinctly described by the psychotherapist as identification with the "horror" girls featured in comics, whose adventures she followed avidly and retold with gusto In short, she was boisterous, provoking, and exhibitionistic In these sessions the "flicking" had frequently been observed, and during the first week of October two petit-mal attacks arose spontaneously

Treatment —After the E E G she was given troxidone 150 mg thrice daily from June 25, 1956 Even when the dose was doubled, this drug was without obvious benefit. Early in September, 1956, she was found unconscious in the garden one very bright morning, and she remained in coma for 2 hours A few days later she had a similar but shorter episode It is not known whether these attacks were precipitated by "flicking" On Sept 19 troxidone was stopped and chlorpromazine 25 mg and primidone 125 mg thrice daily were begun Neither these drugs nor the use of rose-tinted spectacles had any appreciable clinical effect Psychotherapy resulted in pronounced improvement in her general behaviour, but it did not reduce the frequency of the "flicking"

Case 2 —A girl, aged 11 years, was admitted to hospital on Aug 21, 1956, because she had been found unconscious in her garden with generalised twitchings of both arms and legs This convulsion lasted about 5 minutes and was followed by a period of unconsciousness which was coming to an end by the time she reached the hospital 6 weeks previously she had fallen down unconscious, she did not twitch in this attack, which lasted only a few minutes

Her parents related that about a year previously, when the family were living in Persia, they had first noticed that the child had developed a peculiar mannerism This was obvious only when there was bright sunshine and when she was out-of-doors She rapidly waved her right hand, the dominant one, to and fro before her eyes, at the same time turning her face up towards the sun She then "appears to go into a trance" On bright days she repeated her habit again and again She first fell down 6 weeks before admission to hospital When her mother reprimanded her, the child said "I can't help doing it" Her mother added "She gets nasty if I try to interfere"

The child's birth had been uncomplicated, and she appeared to develop normally She was pot-trained from the age of 11 days After her 5th birthday she had a series of exanthemata, and also acute nephritis for which she spent 7 months in hospital There, according to her mother,

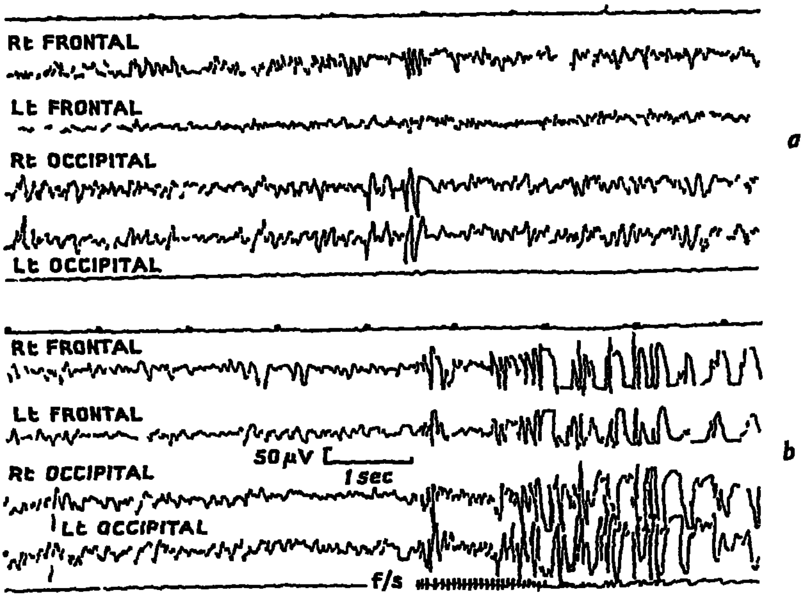

Fig 1—Case 1 (*a*) Resting record showing wide range and abnormal bursts of high-voltage spikes mainly in occipital region (*b*) Stroboscopic activation at 15–16 flashes a second producing atypical spike and wave lasting for 2–3 seconds

she was "spoiled", and subsequently became bad-tempered and selfish at home, though by contrast absurdly generous to strangers Menstruation began in August, 1955, but she had not had a period since May, 1956

There was no family history of epilepsy Her young brother, aged 9 years, was in good health On her own admission the mother was over-protective with both children, and more attached to the boy The schoolteacher described the patient as quite intelligent but very highly strung, she was backward in all subjects, especially arithmetic, and cried easily if reprimanded At home she was often anxious about her schoolwork, and if worried went off her food It was extremely difficult to establish rapport with this mother, who once spontaneously confessed to feeling "cut-off" from people This rather suggests a schizoid personality

Clinical examination revealed no signs of organic disease The patient was a thin, cooperative child who showed apprehension whenever her "habit" was mentioned

Electroencephalography —The resting record was normal with a well-sustained basic alpha rhythm at 10 cycles a second Hyperventilation made little alteration in her record. Stroboscopic activation at 14–15 flashes a second produced an atypical spike-and-wave abnormality, but only when the activation had lasted for 3–4 seconds (fig 2)

Psychological testing was carried out during the child's short stay in hospital She was very tense and showed little perseverance Her intelligence rating was low-average There was no evidence of any visuomotor disturbance In the projective (thematic apperception) test most of the themes which emerged were concerned with failure or the loss of treasured possessions She was a slim, rather angular child with small regular features and fair colouring The movements of her head and limbs tended to be rather jerky A slightly agitated manner revealed her anxiety in the early sessions, but there was, if anything, less shyness than is usual in a girl of this age In fact, this social precocity gave an initial impression of higher intelligence than she possessed In the first psychiatric interview, after recounting something of her life in Persia, she was asked why she was in hospital and explained curtly "I wave my hand" Further questioning elicited the fact that this produced a dreamy feeling, and sometimes fits "I don't like fits, I fall asleep and it takes me an hour to recover" She admitted that she always had dreams during postictal sleep but would not discuss their content. She was emphatic that she never dreamt during ordinary sleep There was no indication that she was upset at returning home from abroad, but a suggestion that she might be worrying about something precipitated a bout of weeping, and with obvious distress the child told in vivid detail how, while she was abroad, one of her favourite horses at riding-school had injured a leg and had to be shot. On her first visit as an outpatient she was again unsure of herself, and her anxiety was revealed in a blinking tic of the right eye and in curious stereotyped movements in which corresponding fingers of her two hands were successively opposed This did not happen subsequently In contrast to the child's customary self-possessed if superficial play and chatter was the gay abandon with which she participated in a game of catch-ball, running and laughing, playfully aggressive and teasing by turn Clearly revealed during these activities was a slight but definite exaggeration of all her movements as if antagonist muscle action was not quite synchronous Even her smile was exaggerated and slow to fade There was no actual motor incoordination She was not observed "flicking" her hand either in hospital or at the clinic A superficial relationship was established easily but did not develop

Treatment —After the E.E.G she was given troxidone 150 mg thrice daily from Aug 20 Neither this drug nor the use of rose-tinted spectacles had any appreciable clinical effect Psychotherapy has proved difficult and, hitherto, somewhat unproductive

Discussion

Both these girls have discovered for themselves the trick of inducing seizures by hand-waving against the sun, and despite criticism continue to do so at fairly short intervals It is interesting to note that an effective rate of stroboscopic activation is around 15 flashes a second, which is a rate that can just be achieved by rapidly waving the five fingers of one hand It is almost certain that, in both cases, seizures arose spontaneously only after being induced Both girls may be considered to have "idiopathic" epilepsy or a striking constitutional tendency to seizures That there is a certain compulsive element in the inducing seems fairly clear from the children's own comments, and in case 1 the child's actual enjoyment is revealed by her remarking during photic stimulation by the stroboscope "that was great", as she squirmed with excitement That this kind of auto-stimulation might be analogous to masturbation had occurred to both sets of parents, but there is no convincing evidence for or against this analogy Again, it is curious that each child invariably "flicked" with the same hand, in one instance the dominant one If this has any significance it may suggest a compulsive ritual, or perhaps a neurophysiological explanation should be sought, in that one half of the visual cortex might be the more sensitive to photic stimulation.

When we come to consider the personalities of the patients the first impression is that, apart from both being reasonably intelligent, they have very little in common—certainly this is true of their manifest behaviour In case 1 the distorted parent-child relationship is of itself sufficient to account for pronounced emotional disorder in the child without invoking "epilepsy" at all, except inasmuch as the child's early behaviour must have modified later parental attitudes In case 2 also, the mother-child relationship is coloured by gross over-protection, and it is not very surprising to observe in the child signs of anxiety and insecurity In both cases, therefore, environmental and constitutional factors almost certainly operate

We have no completely convincing explanation for the time of onset of the "flicking" habit, though it is possible that the impending loss of a nanny in the one case and of a beloved animal in the other may have amounted to situations of emotional stress or conflict

Treatment by drugs, rose-tinted lenses, and psychotherapy has not as yet met with any conspicuous success However, we have not yet exhausted the possibilities of a "trial-and-error" approach, and we intend to follow up carefully the progress of these patients

Summary

The cases of two girls are reported in which epileptic episodes were induced by photic self-stimulation of a compulsive nature

The diagnosis was confirmed by electroencephalography Psychological techniques were used in the assessment of personality

Treatment by physical and psychological methods has proved unrewarding

Preliminary Communication

A NON-TOXIC COMPLEX FROM PASTEURELLA PESTIS WHICH IMMUNISES BOTH GUINEAPIGS AND MICE

THE following cardinal facts emerge from the extensive literature on immunisation against plague in experimental animals and in man.

1. Mice can be effectively immunised against plague by dead vaccines, but only low-grade immunity is produced in guineapigs by such vaccines.[1]

2. Guineapigs (and mice) are effectively immunised against plague by living attenuated vaccines.[2]

3. The use of living attenuated vaccines in man was prompted by the cogent argument that man should have the benefit of antigens which immunised both mice and guineapigs.[2-4]

4. Mice could be effectively protected by fraction I,[5] the non-toxic envelope substance obtained from saline extracts of acetone-dried *Pasteurella pestis*. This fraction, however, had a much lower protective effect for guineapigs. Some protection in guineapigs was afforded by the so-called "residue antigen" which had a small protective value for mice. The "residue antigen" was that left after extraction of acetone-dried organisms with saline; it appeared to consist of 70–75% of the whole organism.

5. The use of fraction I for immunising man suffers from the possible disadvantage of the low-grade effect observed in guineapigs.

6. Vaccines prepared from whole dead *Past. pestis* are toxic, and this limits the quantity that can be injected.

In view of the efficacy of living vaccines in guineapigs, we examined first the protective activity, in guineapigs and in mice, of fractions obtained from large quantities of *Past. pestis* separated from guineapigs dying of plague. These studies demonstrated the presence in such organisms of a non-toxic complex which immunises both guineapigs and mice. Later a similar complex was obtained from certain cultures in vitro.

OBSERVATIONS

Our method of collecting *Past. pestis* from infected guineapigs has been described elsewhere.[6] An aqueous suspension containing 1 × 10¹⁰ per ml. was treated with ultrasonic waves for one hour at 3°C. The soluble extract, which killed both mice and guineapigs when injected intravenously, constituted about 70% of the whole organism. It would not actively immunise guineapigs in a test similar to that described in the table, and in mice was too toxic for an adequate test to be made.

The residue from ultrasonic treatment was resuspended in water and subjected to ultrasonic waves for an hour at +3°. After removal of the supernatant, which contained very little soluble material, the procedure was repeated. The twice-washed residue contained no intact *Past. pestis* when examined microscopically and in the electron microscope. It constituted about 30% of the whole organism and dissolved almost completely when treated with ultrasonic waves in 0·05*M* $NaHCO_3$ or 0·02M tris(hydroxymethyl)-aminomethane at pH 8·5 or 8·7 respectively. It was examined in toxicity and active-immunity tests with mice and guineapigs at a concentration equivalent to 1 × 10¹⁰ organisms per ml., either as a suspension in saline solution (heated at 60° for an hour) or as a solution in 0·05*M* $NaHCO_3$ buffer at pH 8·5 (filtered through 'Millipore'). Each preparation proved harmless to mice and guineapigs in doses of 0·5 ml. intraperitoneally and 5·0 ml. subcutaneously respectively. The successful results of active-immunity tests in mice and in guineapigs are shown in the upper half of the table.

[*] Suspension of *Past. pestis* (1 × 10¹⁰ per ml.) subjected to ultrasonic waves. The washed residue (about 30% of whole organisms) was suspended in saline or dissolved in 0·05*M* $NaHCO_3$ to the original volume.

† Virulent L37 and avirulent Tjiwidej strains grown at 37° in the medium described by Davies[7] and harvested at 20 hr.

Active immunity test—2 subcutaneous injections of protective antigen with a two-week interval—challenge after one week with approximately 100–1000 L.D. of *Past. pestis* (strain L37).

A solution of the well-washed, lipid-containing residue in 0·05*M* $NaHCO_3$ at pH 8·5 showed one precipitation line on Ouchterlony diffusion plates[8] against plague antiserum; this line was common with that produced by the freely soluble fraction I isolated as described by Baker et al.[5] When serum was used, absorbed with an avirulent organism to detect virulence antigens as described by Burrows and Bacon,[9] the solution of the residue also formed a line of precipitation. The relation of these lines to one another and to those virulence antigens previously described[9] is under investigation. In this connection, it is relevant to mention that the solution of the residue in bicarbonate buffer prevented the phagocytosis of *Past. pestis* by guineapig polymorphs; fraction I and the virulence antigens have already been associated with phagocytosis resistance.[9,10]

COMMENT

It appears that the residue from ultrasonic treatment is a complex containing fraction I, a virulence antigen, and at least one other lipid-containing component. We suggest that *Past. pestis* has a cell-wall complex containing lipid, to which fraction I is attached firmly near the cell wall and loosely in the body of the envelope. The same state of affairs probably exists with respect to the virulence antigens. This cell-wall complex with the attached envelope can then be regarded as the best antigenic material for the protection of all species. If it is split by autolysis, acetone drying, and to lesser degree by washing or treatment with ultrasonic waves, then the components lose some of their protective power. This loss may be more apparent in some species than in others, as evidenced by the different protective power of free fraction I for mice and guineapigs.

The protective complex, first recognised in *Past. pestis* grown in vivo, may form the basis of an efficient dead

vaccine for man Thus it is relatively non-toxic, it has been obtained in a soluble form which can be filtered sterile and freeze-dried, and, unlike previous dead vaccines, it immunises both guineapigs and mice

The practicability of such a vaccine depended on *Past pestis* forming a similar complex under certain conditions in vitro, and recently we have found this to be so Thus, suspensions of similar ultrasonic residues obtained from cultures of the virulent L37 strain and the attenuated immunogenic Tjiwidej strain, were similarly non-toxic and actively immunised guineapigs and mice (see lower half of table†) Such preparations, used alone and with added free fraction I, are being investigated as practical vaccines against plague

New Inventions

A MACHINE FOR FREEZE-DRYING AND STORING TISSUES UNDER ASEPTIC CONDITIONS

This machine (fig 1) was developed to eliminate the imperfections and to overcome the disadvantages of existing apparatus It was designed especially to avoid the risks of bacterial contamination by carrying out in a single tube with an uninterrupted vacuum the whole process of freeze-drying, desiccation in vacuo over phosphorus pentoxide, storage, and eventual rehydration

Apparatus

The main body of the apparatus consists of a cylindrical manifold with eight ports into which the artery tubes are fitted (fig 2), but it is to the design of the artery tubes that the machine owes most of its originality Fig 3 shows the detail of one of these tubes, the ground-glass joint of cap and tube is in effect a wide-bore tap because, by turning the cap, its port can be made to coincide with the corresponding aperture in the ground-glass surface of the tube

The eight ports for the artery tubes are ground-glass sockets into which fit the side arms on the caps of the artery tubes One end of the manifold leads via a wide-bore tap to a conventional vapour condenser and thence to the pump To avoid dangerous mechanical strains the various articulations are effected by spherical instead of the usual conical ground-glass joints At the other end of the manifold there is an easily removable brass closure which gives access to a boat containing P_2O_5 with a closely fitting ground-glass lid to protect the desiccant from water vapour during the initial stages of freeze-drying This lid can be lifted from the P_2O_5 boat, without disturbing the vacuum, by means of a plunger mounted in a vacuum-sealed shaft on the top of the manifold (fig 2)

Method of Use

Arteries are removed from the donor with full aseptic precautions After being cut into suitable lengths, cleaned, and washed with streptomycin solution to counteract possible coliform contamination during agonal bacteriaemia, they are threaded on plastic formers and placed in the previously sterilised artery tubes One tube serves as a bacteriological control If it is inconvenient to begin lyophilisation immediately, or if only a short time has elapsed between death and the taking of the arteries, and agonal vascular spasm has not yet relented, the tubes are part-filled with sterile saline solution containing streptomycin and are immersed for a few hours in ice and water in the Dewar flask During this stage the contents of each tube are kept sterile by a glass cap that seals the open end of the side channel in the top of the tube (fig 3)

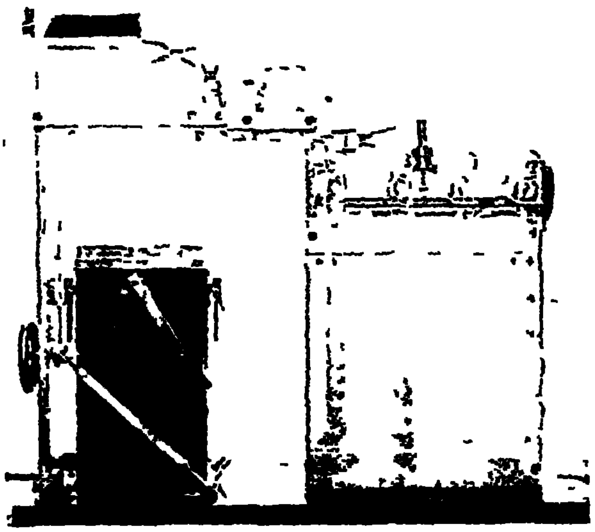

Fig 1—The machine, showing two long and two short artery tubes plugged into the manifold, on top of which is the plunger for lifting the lid of the phosphorus-pentoxide boat Beneath the manifold, hidden from view, is a Pirani gauge On the left the Dewar flask is ready to be raised to cool the condenser

To prepare for the freeze-drying the saline solution is poured out and the tubes are placed in a CO_2-alcohol freezing-mixture in the Dewar flask until the tissues are hard-frozen, the tubes are then transferred to the machine

The freezing-mixture in the Dewar flask is now used to cool the vapour condenser (fig 1), and pumping is begun The latent heat of vaporisation of water from the tissues is sufficient to keep them frozen After 10–12 hours the tap at the end of the manifold is closed, and the lid is then lifted from the P_2O_5 boat

The vacuum is checked from time to time, and, if necessary, pumping is resumed

After four days desiccation is considered to be complete, and the artery tubes are sealed by rotating them inside their caps, to keep the side arms of the caps sterile they are in turn sealed by sterile glass caps fitting over their open ends The tubes containing the dried tissues are stored at room-temperature and have been found to maintain their vacuum

For the freeze-drying of bulky tissues fruit-bottling jars can be used after modification by the addition of ground-glass jointed caps as described above

The body of the machine, when not in use, is kept sterile by formaldehyde tablets placed in glass stoppers plugged into the ports on the manifold

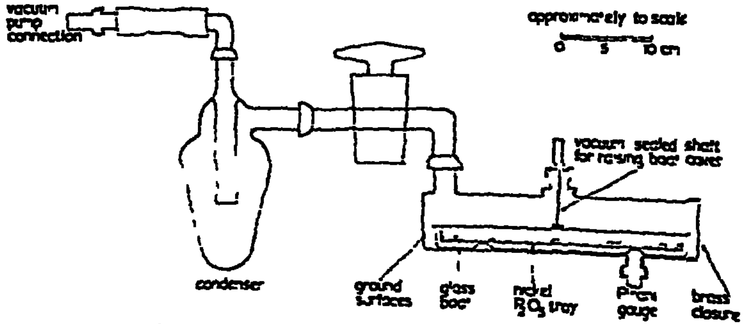

Fig 2—Design of apparatus. Ports for artery tubes are not shown.

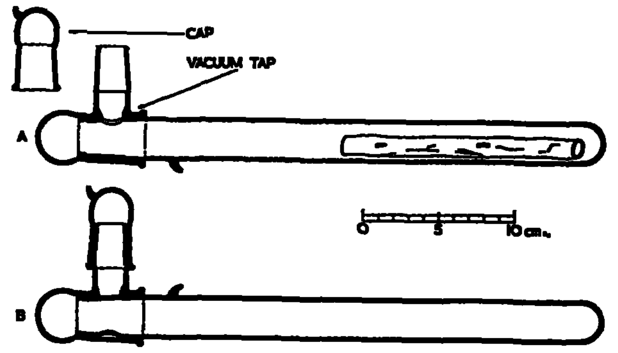

Fig 3—Artery tube Cap and tube form, in effect, a wide-bore tap Rotation of cap to position A opens this "tap" for freeze-drying, and turning to position B seals it for storage The second cap sealing the side arm in B is used to keep this channel sterile

Reconstitution

When the tissues are required for grafting, the cap is removed from the side arm of the tube, and a sterile glass funnel is attached and filled with sterile Ringer's solution (fig 4) The artery tube is slowly rotated inside its cap to allow the Ringer's solution to be sucked in After 20 minutes the artery is removed from the tube, the side branches are tied, and it is ready for grafting

Comment and Results

Bacteriological studies have confirmed that tissues processed in this way remain sterile Macroscopically the arteries after reconstitution are indistinguishable from fresh vessels, and microscopically the only abnormality is pyknosis of the nuclei They have proved satisfactory in use

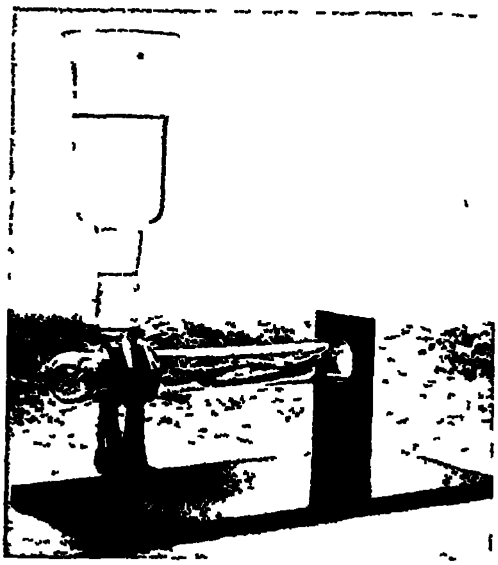

Fig 4—To reconstitute the dried artery, a funnel containing Ringer's solution is attached to the side arm of the artery tube, and the body of the tube is rotated until the hole in the side of the tube and that in the cap begin to coincide, whereupon the fluid runs into the tube and is sucked into the tissue

The apparatus depicted in these photographs was made by one of us (A L) for Prof P Santy at Lyons University We are most grateful both to him and to Prof J H Burn for their encouragement We are indebted to Mr E L Tugwell for the photographs

Reviews of Books

A Short History of Psychotherapy

NIGEL WALKER, PH.D London Routledge & Kegan Paul 1957 Pp 184 25s

CHAIRMAN of the Davidson Clinic in Edinburgh, Dr Walker has written a workmanlike and readable summary of the development in theory and practice of modern psychotherapy He reminds us in his introduction that this, like psychiatry, itself, is not a science but a technique, and the importance of theory to those using a technique is that it should provide suitable explanatory models

The modern semantic treatment of psychological illness is traced from Freud's earliest work on hypnosis, with a brief backward glance at Mesmer, through the period of "primitive psychoanalysis," when Freud was making his discoveries of the Unconscious and of techniques for exploring it The work of Adler, of his modern successor, Carl Rogers, and of Jung is also outlined and the main points of theory and technique are described Suggestion and conditioning, the only trends not derived from Freud's ideas, are given a chapter, describing the Nancy school and Emile Coue on the one hand, and Pavlov and the reflex school on the other

Dr Walker's account of the various schools is throughout objective and free from obvious bias, and his final summing-up of their relative merits and efficacy, and the type of patient most likely to benefit from each, is the more convincing because he pleads no special case

The Bases of Treatment

NEWTON S STERN, M.D, associate professor of medicine, THOMAS N STERN, M.D, instructor in medicine, University of Tennessee College of Medicine, Memphis, Tennessee Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 176 36s

IN framing effective treatment the doctor must have not only proper understanding of disordered physiology but also an imaginative appreciation of the psychological effects of disease This book attempts to cover these important subjects, and fluid and electrolyte balance, diet, the comfort of the patient, and psychotherapy are among its topics The chapter on drugs is largely confined to a consideration of digitalis and penicillin Powerful new remedies may occasionally do harm, and the importance of iatrogenic disease is rightly discussed

The book is written at an elementary level and is designed as an introductory course in the principles of therapeutics Though the intention is sound, the execution is not always successful The ever-present risk of over-simplification has not always been avoided, and we should have preferred a more critical approach to both the results and the limitations of therapy

Extensile Exposure (2nd ed. *Edinburgh* E & S Livingstone 1957 Pp 320 45s)—That there has been a demand for a second edition of Prof A K Henry's now classic monograph will surprise nobody who has had the pleasure and benefit of reading the original He is one of the happy few who can combine anatomy and surgery with artistry, and his highly individual style is displayed in vivid writing and subtle choice of words Most of the original text has been left unchanged, but he has added a section on access at the second left costal arch, and another on the hypogastric route, so that the new edition is nearly twice as long as the first Both new sections are rich fare, and there is now something for all—except perhaps the ophthalmologist All surgeons should read the book There is no pleasanter way of revising anatomy

Hormones in Blood (Ciba Foundation Colloquia on Endocrinology Vol II London J & A Churchill 1957 Pp 409 56s)—Under the chairmanship of Dr A S Parkes a group of scientists from Europe and the United States met last February to discuss circulating hormones, as opposed to their urinary fractions, analogues, or metabolic products The papers have been edited by Dr G E W Wolstenholme and Miss Elaine C P Millar

COMPOUND SULPHONAMIDES

There are many infections in which sulphonamide therapy is clearly indicated The difficulty is that high dosages of a sulphonamide may produce sensitization reactions, crystalluria and other undesirable side-effects

This is why 'Sulphatriad' is so valuable Its effective action is the sum of the virtues of its three powerful constituents, and combines rapid absorption with a good tissue distribution But as the risk of crystalluria is relative to the concentration in the urine of a single sulphonamide, 'Sulphatriad' means reduced concentrations — and reduced risk

Estimating Fœtal Maturity

ONE of the most difficult decisions the obstetrician is called on to make concerns the termination of pregnancy on account of severe toxæmia, cardiovascular disease, or other maternal disorders If he interferes too early the fœtus may not be viable, but should he delay too long the mother's health may be endangered and the risk to the baby may also increase When the date of the last menstrual period is uncertain the maturity of the fœtus may be estimated by clinical examination, but such estimates are notoriously inaccurate owing to individual variation in such factors as the level of the umbilicus and the thickness of the abdominal wall An X-ray examination is sometimes requested, in which case the radiologist's opinion is usually based on the time of appearance of fœtal ossific centres or the size of the fœtal head, but no great accuracy has hitherto been claimed for this method For example, ROHAN WILLIAMS[1] states that dates of ossification vary widely, he gives the time of appearance of the centre for the os calcis as between the 21st and 29th weeks, and that for the talus between the 24th and 32nd weeks HODGES[2] devised a method based on the size of the fœtal skull, but the particular diameters required cannot always be measured, and in any case there are large biological variations in the dimensions of the fœtus in the second half of gestation

Since 1949 HARTLEY,[3] in Manchester, has carefully studied thousands of antenatal radiographs, correlating all the known or subsequent information regarding the last menstrual period, date of delivery, appearance of the baby at birth, and, in many cases, postnatal X-ray examination He has shown that the times of appearance of the fœtal epiphyses do not vary as widely as was formerly believed for example, he has found that the centre for the os calcis appears consistently between the 24th and 26th week, while that for the talus appears just as regularly between the 26th and 28th week His investigations have also exposed the fallacy of estimating maturity at a later stage of pregnancy from the appearance of the cuboid He has shown how consistently the epiphysis for the lower end of the femur appears by the 36th week, and that for the upper end of the tibia at 38 weeks Previous workers had based their estimates of fœtal maturity mostly on anatomical investigations which by their very nature could not be followed through to postnatal life and which were few compared with the potential material of a large X-ray department When the X-ray department at St Mary's Hospital Manchester, was opened in 1949, very few patients were referred for radiological estimation of fœtal maturity, yet in 1956 this was the examination requested in 25% of 1000 antenatal cases. This indicates the demand for such information and it is also a testimony to the value of HARTLEY's work From the beginning he required a very high standard of radiographic technique, and this was the foundation of his success, for developing fœtal epiphyses are not easily seen, and they need a radiograph of the highest quality on every occasion As a result of painstaking observations on thousands of patients HARTLEY can now estimate maturity in many cases to within a week, and a recent pilot survey showed that 77% of patients were delivered within 14 days of the estimated date

Only two years ago HARTLEY's report would undoubtedly have inspired a greatly increased demand for X-ray estimations of fœtal maturity, but now the reception of his work may be modified by STEWART's[4] account of a possible association between antenatal X-ray examinations and leukæmia in infancy The impact of her preliminary findings has been considerable in one large city a memorandum, signed by obstetricians and radiologists, was circulated to all consultants and general practitioners recommending, among other restrictions, that "routine" pelvimetry and placentography should be stopped Such examinations should never be regarded as "routine", and the memorandum may be more discouraging than its authors intended As STEWART[5] remarked, "antenatal radiography should continue to be regarded as a valuable and essential means of saving life, always provided that it is restricted to cases in which there is 'a definite clinical reason for referring patients for this examination'" WITTS[6] said ' we must balance the risks of X-ray diagnosis and therapy against their benefits The possible 50 cases of leukæmia a year from X-radiation in utero must be set against 439 deaths of mothers in childbirth, 15,829 stillbirths and 9750 deaths in the first week of life in 1955 Obstetricians and radiologists believe that the mortality of mother and child may be significantly reduced by the appropriate X-ray examinations in pregnancy, and that they can save more lives than are likely to be lost from leukæmia."

Treatment of Breast Cancer

UNCERTAINTY has lately prevailed about the best treatment for breast cancer After years of unquestioning loyalty to radical mastectomy, surgical peace of mind has been disturbed by MCWHIRTER's suggestion[7] that axillary metastases are better treated by irradiation without axillary dissection, and, since logic points to the futility of axillary dissection when no metastases exist there, what purpose can radical mastectomy serve? MCWHIRTER[8] has added to these arguments WANGENSTEEN's observation[9] that in 60% of cases with invaded axillary nodes, either supraclavicular or internal mammary glands were also involved, and neither of these groups falls within the scope of radical mastectomy as commonly practised today Describing their technique for the excision of the internal mammary chain, HANDLEY et al[10] reported invasion of these glands in 40% of their series of 57 cases (in 55 of which the primary lesion was in the inner or central part of the breast) McWHIRTER computes that of 1882 cases seen between 1941 and 1947, for only 36% would radical mastectomy have been effective—for those without axillary-node involvement 22%, and those with axillary-node involvement alone 14% On the other hand, 85% of cases were suitable for simple mastectomy and radiotherapy—namely, all except those with distant metastases (15%)

[9] Wangensteen, O. H. Proceedings of 2nd International Cancer Conference, 1952, 1, 23[illegible]

A strong challenge now comes from the Mayo Clinic[11] where 9649 patients were seen between 1910 and 1954, 9477 of whom were submitted to radical mastectomy alone, the rest to simple mastectomy For the 1918 cases treated in 1941–47, the five-year survival was 59 3%, as compared with 48 1% in McWHIRTER's group treated in the same period BERKSON et al[11] think it is reasonable to suppose that benefit may accrue from significant reduction by surgery of the cancer mass, they hold that the effects of treatment in this respect do not obey an all-or-none law and that inability to remove every cancer cell, including those which may be lurking in supraclavicular or internal mammary regions, cannot be regarded as therapeutic failure Though they concede that axillary dissection might lead to dissemination, as McWHIRTER suggests, they know of no evidence by which this factor may be assessed They also doubt the significance of the improved results noted by McWHIRTER in the group receiving simple mastectomy with postoperative radiotherapy between 1941 and 1945, as compared with those treated in 1930–1934 by radical mastectomy alone and in 1935–1950 by radical mastectomy and radiotherapy[12] They are not convinced that the improvement was really related to treatment since they noted a persistent improvement in survival with each successive quinquennium in their own group —probably the result of earlier diagnosis and earlier surgery From Birmingham also, where 4757 cases were seen between 1936 and 1949,[13] this same trend of improvement was noted with the progress of time The 39 4% five-year survival-rate for the whole period at Birmingham only serves to emphasise the discrepancies between the various groups, for this includes all cases, even those untreated by surgery or radiotherapy, and is comparable with absolute survival-rates from 11 different centres cited by ROSAHN[14] Comparison between the figures from the Mayo Clinic and those from Edinburgh is difficult since at the Mayo Clinic operative deaths have been excluded (though these were few, being 61 or 0 6%) and cases not operated upon were not recorded, whereas 257 inoperable cases were included in McWHIRTER's results ACKERMAN,[15] who had the opportunity of studying McWHIRTER's 1941–47 cases, points out that in at least 220 ovarian sterilisation by irradiation was also performed in addition to simple mastectomy and local irradiation The Birmingham results have both the advantage and the disadvantage of being more comprehensive, for each therapeutic technique and combination is considered separately in relation to the extent of the growth (by Manchester staging), and recurrences are recorded as well as survival-rates—an advantage since closer comparisons may be made, a disadvantage since the analysis is more complicated From these figures radiotherapy associated with radical mastectomy seems to be more effective than radical mastectomy alone, as judged by five-year survival in stage 1 cases, on the other hand, a higher recurrence-rate followed the combination of deep X rays and surgery when nodes were involved—a peculiar equivocation that is hard to explain, just as it is hard to equate these conclusions with ROSAHN's finding either that five-year survivals are not significantly influenced by different methods of treatment or that various treatments influence survival statistics equally[14 16] There is one humbling fact tucked away in the welter of Birmingham figures—only 4 2% of deaths were due to causes other than breast cancer

Staphylococcal Infection in Infancy

STAPHYLOCOCCAL infection originating in maternity hospitals is such a common cause of death and disease that it would be better if only selected deliveries took place in hospital This is the opinion of RAVENHOLT et al,[17] who investigated infection-rates in mothers and babies from fifteen Seattle hospitals after they had returned home 714 families were studied, and it was found that mastitis developed in 31 mothers (4%), and 125 babies (18%) had skin sepsis 41 children born during the period under investigation died before they were 3 months old, 5 of these were proved to have died of staphylococcal disease How long infection with the staphylococcus has been a problem in maternity hospitals, and how serious this problem is, cannot easily be estimated, because there are several forms of staphylococcal infection In the first place there is the outbreak of sepsis, which follows a typical epidemic pattern and is usually controlled only by drastic measures such as closing the unit or wholesale prophylaxis with antibiotics Secondly, there are the spots and sticky eyes which used to be considered quite normal in the newborn, and which still seem to arise at a fairly constant rate The third type is the symptomless colonisation of infants with staphylococci, this has been shown to happen to nearly every baby by the time it leaves hospital

Outbreaks of pemphigus neonatorum were described by RIGBY[18] in 1835 and by TILBURY FOX[19] in 1864, and both these workers recognised the contagious nature of the disease Its staphylococcal origin did not become clear until the nineteen-twenties, at one time it was thought to be syphilitic, and later was said to be caused by streptococci But it was recognised as a definite clinical entity which occurred in epidemics This comparatively clear-cut picture became confused when we began to find out more about the organism Coagulase-positive staphylococci were isolated not only from the lesions but also from the nostrils of about 45% of healthy adults, 75% of nurses, and practically every baby over 4 days old How could one hope to prevent staphylococcal disease when the organism was so widespread? The introduction of phage-typing has shown that there are some kind of tracks in this staphylococcal wilderness In outbreaks of severe sepsis one particular strain, which may not be the most common one, is usually isolated from the lesions The virulence of a strain cannot be safely assessed from its phage-type, but there has been at least one example of a particular type being associated with a capacity to cause disease This is phage-type 80, which has been the epidemic organism in severe outbreaks in Australia, New Zealand, Canada, the United States, and Britain since 1953 Phage-typing has been used to find and exclude or treat carriers of the epidemic strain This method is often successful, and ROUNTREE et al.[20] in Australia and GILLESPIE and ALDER[21] in this country have shown that some nasal carriers can be cleared of staphylococci with ointments containing antibiotics The epidemic strains are nearly all resistant to the common antibiotics, and the more these are used, the more the resistant strains will be selected The clinical form of the disease seems to have changed since the late war Nowadays, pemphigus is uncommon, the virulent staphylococci seem to act on the deeper tissues, producing abscesses, cellulitis, meningitis, osteomyelitis, and pneumonia Staphylococcal pneumonia of infants is being recognised more often, and its origin in maternity hospitals appreciated This is a particularly deadly disease because diagnosis is difficult and the course rapid HARLEY,[22] in Sydney, found that the average time between the onset of pneumonia and death was five days, of 19 infants with this disease, 7 died He recommends that every case of pneumonia in a baby should be treated as staphylococcal until it is proved to have a different cause

This then is the basis for the opinion of RAVENHOLT et al They were particularly impressed by the danger of hospital-derived staphylococcal disease because they did not limit their investigation to the hospital nursery They extended their studies by the simple (in America) technique of telephoning the mothers in the second month after delivery A considerable amount of sepsis was found to have occurred after the mother and baby left hospital An outbreak in one hospital nursery was followed by an epidemic of sepsis in the mothers and babies at home, caused by an organism of the same phage-type How long these strains persist in the community is not known, but a finding by ROY et al[23] of Toronto may be relevant Antibiotic-sensitivity tests were carried out on staphylococci isolated from children admitted to a pædiatric unit The incidence of resistant organisms was considerably higher in this group than in adults examined in other investigations This, ROY et al say, might be due to the persistence of organisms acquired in maternity hospitals In this country mothers stay in maternity hospitals longer than the four days described by RAVENHOLT, so that relatively more staphylococcal infection will take place in hospital He gives the median time for the development of sepsis as eight days for infants and fourteen for mothers, so we are less likely to miss the immediate post-delivery infections Once the mother and baby have returned home there is little machinery for connecting any illness they may have with the hospital where the confinement took place Staphylococcal disease is not notifiable, and the only follow-up is the routine post-natal examination of the mother and the visit of the health visitor to the home It would be easy for an outbreak of hospital-derived staphylococcal sepsis to pass unnoticed RAVENHOLT and LA VECK[24] in an earlier investigation wrote to twenty-six hospitals in Seattle-King county asking them about their experience of staphylococcal disease They remark that "staphylococcal disease is a major problem in the better hospitals—the ones that have pathologists and good laboratories and a hospital-infection record-keeping system Administrators of hospitals without such resources usually stated that they had no staphylococcal disease problem" Does this apply also to this country?

Annotations

PROSPECT OF POWER

THE statements issued last week about the British and American work on the control of thermonuclear fusion reactions were wisely cautious They were not, therefore, as exciting as some people had forecast a new and abundant source of cheap power is not just round the corner But there can be no doubt that remarkable progress has been made and difficulties have been surmounted which, a few years ago, seemed a complete bar to the extraction of power from this source

To achieve a net gain in energy from the fusion of heavy-hydrogen nuclei (deuterons) it will be necessary to heat the gas to at least 100 million degrees Centigrade and probably more, and one of the enormous problems is how to control and confine the hot gas so that it does not melt and vaporise the apparatus containing it So successfully has this been tackled that in the zero-energy thermonuclear assembly at Harwell temperatures of up to 5 million degrees have been recorded for as long as a few thousandths of a second The smaller device, Sceptre III, at Aldermaston, has got up to about 4 million degrees In the United States the Columbus apparatus at Los Alamos has produced temperatures estimated at between 3 and 5 million degrees for a few microseconds, and in another American machine, oddly named the Perhapsotron, neutron emission was consistent with a temperature of 6 million degrees during a pulse of 60 microseconds Details of these momentous results are recorded in *Nature* of Jan 25

One guide to the performance of ZETA and the other machines is the number of neutrons emitted while the current is flowing in the discharge tube It has yet to be proved conclusively that the neutrons so far observed are the products of thermonuclear fusion There is no doubt that each neutron is generated by the union of two deuterons to form a helium-3 nucleus plus a neutron, but the deuterons may conceivably have acquired the energy necessary for fusion by processes other than heating (such as acceleration by magnetic fields in the discharge) It should not be long, however, before this point is settled, and in Sir John Cockcroft's view it is 90% certain that ZETA's neutrons are true thermonuclear neutrons—in other words, that a thermonuclear reaction has been controlled and a great scientific milestone passed

USE AND ABUSE OF DRUGS BY ATHLETES

OF drug addiction of any kind by athletes there is no evidence whatever in this country, and very little if any in the rest of the world, said Sir Adolphe Abrahams in opening a discussion, in London on Jan 21, by the Society for the Study of Addiction He was referring to a manifesto by the American Medical Association, at its convention last June, which denounced as shocking and vicious the use by athletes of the powerful drug amphetamine Described as by far the most dangerous drug existing today, it can, said the Association, produce violent, rapacious, and criminal behaviour, by converting the ordinary athlete temporarily into the super-type, "pep-up pills" have accounted for the striking athletic records of recent years Athletes, coaches, trainers, and officials indignantly repudiated this charge as ridiculous and without foundation American drug manufacturers issued a declaration claiming that more than twenty years' clinical experience had demonstrated that amphetamine was one of the safest drugs in medical practice

Amphetamine, although previously in use, came into prominence in the 1939–45 war as "energy tablets" given to the Armed Forces Its recognisable effects were to postpone sleep, and to prolong the will to hang on and continue beyond the point at which fatigue would otherwise be overwhelming It elevates the mood and often permits a disregard of physical danger It creates euphoria—a feeling of exhilaration, an increase of confidence, and, as a result, an increased capacity for work, but, as R A F investigators found, the quality of the work is not enhanced, and is in fact a little impaired In saying that, save in the excitable or exceptionally intolerant, no ill effects have been recorded, Sir Adolphe was presumably speaking of single doses, not of the consequences of addiction

He went on to remark that there will always be an ineradicable belief in the existence or discovery of some substance—food or drug—that has the property of increasing muscular efficiency and preventing or delaying fatigue These potentialities have been accorded on the one hand to the simplest materials to be found on kitchen shelves, and on the other to secret concoctions reminiscent of the black magic of witch doctors That effects can be produced is undeniable That these effects result from any active properties in the material administered is a very different question An athlete on the eve of competition is in a highly suggestible state, prepared to confide his well-being to the hands of anybody in whom he has confidence Anything given with sufficient ceremony may be credited with remarkable capabilities, provided that the administrator has the right personality

The Amateur Athletic Association have issued a rule that "drugs may not be used to produce better athletic performances", but their request to the British Association of Sport and Medicine to make clear what is a drug demonstrates the difficulty of drawing a line where legitimate measures end and reprehensible practices—so-called "doping"—begin No reasonable person would object to tea and coffee, although they contain caffeine Alcohol has medicinal properties, and only convinced abstainers would forbid beer, brandy, and wine, which occasionally are of distinct benefit to athletes Are we, asked Sir Adolphe, to refrain from the use of drugs that sharpen the appetite, improve digestion, and so contribute to physical wellbeing? Or from a simple sedative to ensure a good night's rest to an overanxious youngster on the eve of a contest?

It is a common experience that, in moments of stress or emergency, hidden reserves are called on to produce exceptional physical strength through the removal of inhibitions that Nature imposes as a protective mechanism—an index of the margin with which the human machine works Are there drugs that can act in a similar fashion by diminishing sensitiveness, paralysing the consciousness of fatigue, the inhibitions that preserve us from over-exertion, eliminating the functions of judgment and self-protection, while increasing the physical output? It is, doubtless, such drugs that alarmists have in mind when they condemn "doping"

Finally, said Sir Adolphe, if amphetamine and cortisone can directly release another reserve of energy, are they not to be accepted as contributing to normal physiological wellbeing? No criticism was heard of the use of oxygen in ascending Everest, if it were practicable to construct a tunnel with an oxygen-enriched atmosphere (66%) in which runners competed, record performances would be accomplished If drugs can be isolated with a certain stimulating or inhibitory effect of advantage to athletes, with the guarantee that no immediate or ultimate harm is suffered, and fulfilling the ethical requirement that they be free from secrecy and universally available, what objection would there be to their employment? An uncomfortable feeling that it would be unsporting to employ an advantage that the giants of the past lacked?

SERVO MECHANISMS IN GENERAL ANÆSTHESIA

IN ether anæsthesia the blood-level of ether is constantly related to the electroencephalographic pattern[1] Thus the depth of anæsthesia can be measured, and narcosis maintained by means of a servo device arranged to administer further doses of ether in response to changing cortical activity Similar mechanisms can be used for other inhalational agents, and even for intravenous thiopentone[2] Such machines operate intermittently, responding when the level of anæsthesia lightens sufficiently to trigger the mechanism But Bellville and Attura[3] have now designed a servo system in which the "on-and-off" oscillation is eliminated Their servo provides a continuous action which constantly readjusts itself and therefore maintains the patient as nearly as possible at an unchanging depth of anæsthesia With such an apparatus the level of anæsthesia can be more accurately and more quickly determined than by clinical judgment, and the interval between appraisal and correction can be considerably reduced Bellville and Attura consider that servo mechanisms will be of value to the pharmacologist, enabling him to study drug action at or near equilibrium conditions The anæsthetist, however, is often concerned with the action of several drugs in one patient, and, as a human servo, must correlate many different responses from varying parts of the patient. The popularity of servo mechanisms is unlikely to mature in clinical practice, at least until they are complex enough to respond to several variables besides the electroencephalogram

WATER

IN Britain the system of water-supply has been built up in fragmentary fashion by local initiative, and there are now in all 1250 water undertakings The Metropolitan Water Board (probably the largest such organisation in the world) and the undertakings of Birmingham, Manchester, and Liverpool supply nearly a quarter of the population of England and Wales, and at the other extreme some very small undertakings supply only a few thousand people Since 1945 Governments have been committed to a policy of re-grouping, but hitherto progress has been slow, since it has depended on voluntary schemes, and undertakings are, perhaps understandably, reluctant to negotiate for their own demise The Water Act of 1945 gives the Minister of Housing and Local Government compulsory powers, but if these were widely applied progress would be even slower, since an order, if opposed, has to go through a special, very long procedure

These facts are discussed in an analysis by P E P,[1] which concludes that there should be comprehensive rationalisation and also greater coordination in all matters concerning water-supply, including pollution, drainage, and fisheries Looking to the future P E.P finds a striking paucity of published information on water resources and likely demands The total rainfall in Britain is, on average, about 130,000 million gallons a day About half of this has to be allowed for evaporation and transpiration, leaving about 65,000 million gallons a day Some of this must be left in rivers to provide a minimum flow, some may not be capable of economic development, and some may be polluted beyond reach of economic treatment. At present the public supply system makes available some 2500 million gallons a day, of which about 1600–1700 million gallons is taken by domestic and commercial users and about 900 million gallons by industry and agriculture In addition industry uses amounts far exceeding those obtained from public supplies, but much of this is not consumed (e g, cooling at electricity generating stations) probably, in all, some 2500–3000 million gallons a day is consumed, and well over 20,000 million gallons a day used

In a forecast based on admittedly incomplete data P.E P estimates that the total of water supplied may be increasing by some 2% a year, without allowing for the increase inevitably resulting from slum clearance The country has water enough "The problem for the water industry is primarily an economic one of the capital costs of carrying water from areas of surplus to those of shortage, and of the costs of treating water which is available but in too polluted a state for normal methods of treatment." The water industry has resp[illegible] increasing gross capital expenditure from an [illegible] £17 million in 1948–49 to an average of £39[illegible] 1955–56, but "If the demand for water [illegible] increase, further investment will be necessary [illegible] in public supplies are to be avoided" Other [illegible] possible In the first place, economy in the [illegible] would help, and industry should not draw [illegible] of pure water for purposes where water of [illegible] will serve Secondly, improved measures [illegible] water are allowing it to be taken nearer the [illegible] rivers, rather than by using impounding res[illegible] unpolluted reaches Thirdly, in some parts [illegible] possible to divert winter excess water into [illegible] ground strata

In this country, P E.P concludes, wate[illegible] likely to suffice for foreseeable demand[illegible] rationalisation and extended capital exp[illegible] needed to make sure that it shall be a[illegible] necessary amount and quality

Public Health

THE PLACE OF THE HOME-HELP SERVICE IN THE CARE OF THE AGED

CATHERINE H WRIGHT
M B Glasg, D P H
ASSISTANT MATERNITY AND CHILD-WELFARE MEDICAL OFFICER

LLYWELYN ROBERTS
M D Lond, M R C P, D P H
MEDICAL OFFICER OF HEALTH, SHEFFIELD

MOST old people look after themselves, perhaps with some supervision and interest from relatives and a variable amount of help from voluntary bodies When all else fails, however, the local-authority services must accept responsibility for them, and nowadays the old are making ever-increasing calls on these services The home-help organisation, in particular, has been strained by their demands This scheme was introduced to assist domiciliary maternity cases and cases of emergency sickness in the home, and these two groups of patients must still be helped The service is also used for educating problem-family mothers But over the past few years in Sheffield it has become virtually a monopoly of the aged infirm

Our efforts to help old people to remain in their own homes, or to return there as soon as possible from hospital, have resulted in making them increasingly dependent on the home-help service They become unwilling to relinquish it, with the result that the number of new calls is greater than the number that can be removed from the list and the load continues to grow What began as an emergency and temporary support has become the main prop for the care of the aged In consequence the other functions of the service are being curtailed Between 1952 and 1955 the number of chronic-sick cases more than doubled (rising from 737 to 1861), but the number of acute emergencies helped fell from 292 to 109 and the number of maternity cases from 187 to 132 It was therefore decided to review the organisation of the service, and assess its value to old people

Results of Survey

In September, 1956, health visitors visited all the 732 households in a representative sector of the city, where old people were being assisted by the home helps They inquired into the circumstances, environment, and health of the old people no medical examinations were carried out

Marital Status and Age

There were in the group 174 married couples, 84 widowers, 421 widows, 13 single men, and 40 single women (table I) In households where the husband is ill the wife usually manages to look after the home and her husband until she, too, is overwhelmed, and in these households our findings relate to the wife Almost five times as many old women as old men were living alone—an expected result in view of women's longer expectation of life, old men left living alone are more likely to be admitted to hospitals and homes, or taken to live with relatives Solitary men who wish to retain their freedom no matter what the cost in comfort are often found in common lodging-houses In a recent survey in Sheffield * it was found that 86 of the 309 men living in common lodging-houses were over sixty-five The number of women in common lodging-houses is negligible

TABLE I—MARITAL STATUS AND AGE

Age	Married couples	Widows	Single women	Widowers	Single men
90 years and over	1	6	—	—	—
80 to 89 years	38	136	4	33	1
70 to 79 years	88	221	25	46	3
Under 70 years	47	58	11	5	9
Total	174	421	40	84	13

498 of the old people were living alone and of these 160 were over eighty

Disabilities

All but a handful of those interviewed were seeing their doctor regularly, but only 14% were regularly visited by a home nurse Since, in 1955, 54% of the visits of the home nurses were to patients over sixty-five, it was surprising that more of those using the home-help service did not use the nursing service too

TABLE II

Incapacity	No of cases		% of total 732 cases
Immobility due to			
arthritic conditions and joint involvements	194	255	34 8
blindness	39		
gangrene, varicose, ulcers, phlebitis, amputations, &c	22		
Debility due to			
weakness, breathlessness, &c , related to cardiac disease	127	221	30 2
chest conditions	49		
postoperative—e g , cancer	30		
anæmia	15		
Feebleness, dizziness, tremor, unsteadiness, &c , due to ageing of the cerebral arteries	189	189	25 8
Incapacity due to			
depression, psychoneurosis, epilepsy	4	67	9 2
other diseases	63		

229 old people had poor vision and found reading difficult or impossible Some were registered as blind or partially-sighted 117 were very hard of hearing Deafness is perhaps as distressing an affliction as blindness, but it does not interfere with the ability to do housework Their other main disabilities were a compound of those degenerative changes and diseases which make up the syndrome of ill health so restricting to the activities and mobility of the ageing (table II)

Help from Relatives and Neighbours

Independence presumes ability to perform simple, multifarious, everyday tasks of the home Half the old people did no shopping and two-thirds no laundering Some sent their washing to the laundry, and any deficiency was made up by relatives, neighbours, and domestic helps Duties undertaken by relatives and neighbours included washing and the heavier jobs such as carrying coal, decorating, and spring-cleaning For 79 households cooking was done by relatives and neighbours Only 38 were entirely without relatives, 514 had sons and daughters, but 185 had only brothers, sisters, nieces, or nephews Regular visits and help from relatives were given in about half the cases Neighbours in many cases provide help or lessen the loneliness of these old people almost as much as their relatives There was a residue, however, who for one reason or another had to try to stand by themselves—one in three never saw any relatives, one in four had no help from relatives and neighbours, and one in six had no visits from them (table III)

TABLE III—HELP AVAILABLE FROM RELATIVES AND NEIGHBOURS

—	Help and/or regular visits received from				Cases receiving	
	Relatives		Neighbours			
	Help	Visits	Help	Visits	No help	No visits
Married couples	83	115	51	80	68	36
Widows	219	290	204	257	90	51
Single women	13	18	19	22	12	10
Widowers	45	55	45	45	16	10
Single men	7	8	5	4	3	2
	367 (50%)	486 (66 3%)	324 (44 2%)	408 (55 7%)	*189* (25 5%)	*109* (14 9%)

---

*Annual report on the health of Sheffield, 1955

Hygiene

We found 48 old people who were living in dirty houses, 77 who were inadequately fed, and 89 showed marked lack of care Some who had obviously lived on a poor diet for a long time professed to a poor appetite and no interest in food, growing disability, inadequate help, and loneliness had resulted in a general deterioration and loss of standards A few were frail and confused and were in need of supervision and help, but we did not find much evidence of obvious mental deterioration Probably this type of case is generally recognised as needing more regular care than can be given by a home-help or home nurse, and relatives assume responsibility or the patient is admitted to hospital

The health visitors thought that 198 cases needed more help, that for 137 cases shorter and more frequent visits would be more useful, and that for 126 cases an evening visit was desirable

Some Difficulties

Though it may seem at first sight that the old people get little help from those who might be expected to give it, there are many mitigating factors In grouped dwellings neighbours themselves are old and dependent on outside help Sons and daughters do not always live near by and may themselves be getting on in years Daughters and daughters-in-law, who carry most of the burden, sometimes have considerable family responsibilities, may be working or be in poor health Too often their task is a thankless one, for many old people become difficult and ungracious There are thus ample reasons why the local authority is obliged to help

Many difficulties are encountered in providing a domiciliary service Sheffield employs about 300 home helps, full- or part-time, yet we are failing to meet all the needs of old people

It is tempting to suggest setting up a register of people over sixty-five, who would be under regular supervision, so that wherever need existed it could be met Apart from the fact that such a procedure would be resisted by many vigorous old people who are in no way disposed to have intimations of mortality thrust upon them prematurely, the cost of the labour force required would be difficult to justify

Old people can all have medical care as a right, and home nursing at the request of their general practitioner enough domestic help, a more general and nebulous commodity, cannot always be found for them, yet this is the king-pin of the care for the aged

Kind of Help

The help needed by the elderly infirm in their own homes ranges from someone who will regularly spend a few hours doing the type of housework which necessitates kneeling or stretching, to someone who will pay daily visits and run through the gamut of duties such as would be undertaken by a solicitous relative This will include washing, shopping, cooking, help with bodily cleanliness and simple nursing services It may include advice on personal business matters, such as pension arrangement or payment of bills in short, the home-help service must provide a comprehensive type of social service Often the provision of help may be nothing but a form of delaying tactics against the day when an elderly person, who wishes to remain independent as long as possible, is taken to live with a married son or daughter, is obliged to ask for a place in an old persons' home, or when infirmity demands removal to hospital Provided the help given is sufficient, the aim of promoting and prolonging an old person's independence is socially and ethically desirable from every point of view

Recruitment

Home helps are largely drawn from the 12 million women in England and Wales between the ages of twenty-five and sixty-five Many of the women in this pool are fully occupied looking after children and husband Old people's homes, hospitals for the elderly chronic sick, canteens, light industry, and the distributive trades all compete for the type of woman suitable for the home-help service This has been recognised by some authorities, who have given their home helps a status and conditions of service that attract the right type of women to take up the work, to some extent at least, as a vocation. Unless a home-help service sets out to be something more than a service of domestic charring, it will not only fail to meet all the needs of old people but will also be in constant competition with private households and hospitals which employ domestic help A home-help service, if it is to become a real social service, must be able to attract women who are balanced and mature enough to handle the elderly with patience, who have enough intelligence and understanding to relate their behaviour to the process of ageing, and who can provide comfort and security as well as competent help

Cost

According to the report of the National Corporation for the Care of Old People for 1956, to keep an old person at home when it is necessary to provide a home nurse, a full-time home help, and night service, will cost more than a hospital bed Superficially it might seem uneconomic to provide a service for one old person in this way, but there is an analogy between the home help given on this scale for a limited period and the case of the seriously ill person who requires to be " specialled " in hospital To provide a costly service indefinitely for an old person at home is, of course, another matter and would be economically impossible

When comparing the cost of looking after an old person at home with hospital care, the average cost per patient must be used and not the cost for the exceptional case In a sample of 200 of the 732 people in this survey only 18 were found to have home-nursing visits as well as a home help The highest total weekly cost of providing home help and home nurse when both were visiting was £2 14*s* 10*d* —for an old person who had daily general nursing and a home help one full day per week. The lowest figure of 15*s* 6*d* was for a patient who had a weekly injection and the aid of a home help for one half-day per week. In the first example a bedridden person is being kept out of a hospital bed with the help of a home nurse, relatives, or friends, supplemented by a home help, and in the second the small amount of help given to an ambulant patient may well be the alternative to removal to an old persons' home

The difficulty arises where the service is stretched too far in an attempt to cover all who have asked for help It becomes inadequate with the result that the old person who is left without relatives and friends must inevitably be removed to hospital almost as soon as she becomes confined to bed Thus of the 732 people in the survey only 30 were confined to bed or wheelchair, and it is obvious that a further number might have been kept in their own homes if the help had sufficed

The cost of keeping an ambulant old person in a home for the aged is about £4 10*s* per week, but the minimum sum of £1 12*s* 6*d* (under review at present) of this is recoverable from the old-age pension It would therefore be economic to spend up to £2 10*s* per week on domiciliary services to enable the old person to stay at home Where the alternative is the more costly hospital bed, it would be economic to spend considerably more than this

A Choice of Priorities

The question we are faced with is that of translating into reality our ideals regarding the care of the elderly in their own homes The problem is not only one of reservations as to the cost but also the more serious difficulty of finding enough home helps of the right type, and it is not easy, when help is limited, to judge priorities accurately

How far are we justified in diluting the time given to those who need it badly so that those whose need is less may share in a service to which they consider themselves entitled? On the one hand we have long waiting-lists of old people who need home helps, and on the other the difficulty of recruiting home helps, a balance must be struck so that a reasonable, though perhaps inadequate, system of care can be provided There must be a good cadre of well-trained home helps, since, even under supervision, they have to work out of direct control but, owing to difficulties of recruitment, some less skilled workers must supplement the regulars The original conception of the home-help service has had to be changed, and conditions and standards of training and remuneration must be improved so that the work is given a better standing, for, as we have pointed out, much is needed from the home help beyond the capacity to clean a room The service can certainly no longer be haphazard in its organisation, nor can it hope to fulfil the needs of old people unless intelligent care and thought is given to each case and its work is supplemented by enlisting every possible source of help from relatives, friends, neighbours, and voluntary organisations

Since the number of aged is increasing and the younger people who must look after them are slowly getting fewer in proportion, there is a strong argument for the assumption by the medical officer of health of the overall supervision of the aged as a group The services and supervision which he is empowered to provide must match his awareness of the extent and nature of the need—in other words, it must be part of a social service and not merely a Domestic Help Scheme It is already realised that all the efforts which can be made on behalf of the aged by voluntary bodies will be required, and the function of these groups cannot be taken over by the local authority Nevertheless, preventive medicine in devising an intelligently conceived domiciliary service for the aged will have a chance of transforming their outlook in the years which must be lived on the debit side of life

The views expressed are personal and not necessarily those held by the Sheffield City Council

Food-poisoning

A new edition has appeared of the Ministry of Health's memorandum on food-poisoning[1] The only major change since the previous edition[2] is that provision is now made for the reporting of cases ascertained by medical officers of health besides those notified by other doctors

Vital Statistics for 1957

The Registrar General has issued provisional figures for England and Wales for 1957[3] The birth-rate (16 1 per 1000) was the highest since 1949, but the death-rate (11 5) was not much different from that in the previous two years The infant-mortality rate (23 0 per 1000 live births) and the stillbirth-rate (22 4 per 1000 live and still births) were the lowest ever recorded in this country

CARE OF THE MONGOL BABY

The First Phase

Alfred White Franklin
M B Cantab, F R C P
PÆDIATRICIAN TO QUEEN CHARLOTTE'S MATERNITY HOSPITAL, LONDON

The birth of a mongol baby presents one of the most difficult and delicate management problems in family medical care Mongolism is, it is true, only one of the many forms of "congenital defect", and the parents' reaction involves no new or different quality What singles out this problem is, first, that it concerns mental defect, and, secondly, that if the presentation is vertex, the first look at the head and the face, before the whole baby is born, can reveal diagnosis and prognosis—the sadder because medicine cannot help

Mongol babies are not all the same, but they are similar, they share appearance, stature, colouring, a happy character, a love of music and rhythm, and the ability to give and to inspire deep affection While intelligence varies widely, and occasionally reaches the standard of the educationally subnormal, the range is as nothing beside the immense potentialities of the normal newborn babe, and full maturity falls short of independence in the complex of modern society

Parents of congenitally defective children can usually accept at birth such internal disease as involves the gut or the heart Anxiety there is, but compassion also, and the saving hopefulness that the doctor can generally give External defects are harder to bear, because the child will be perhaps crippled or unsightly, but if the parents are given honestly and without delay the whole picture of what can be done and what cannot, after their grief they usually adjust themselves and rise to the occasion Feelings of shame and guilt, or of retribution and punishment, are present in small degree, but where there is mental defect these feelings may well swamp compassion and substitute self-pity and a self-protective aggressiveness—understandable, forgivable, but making it hard for anyone outside to help

These attitudes are usually modified by the quality of the particular parents—strength of character, emotional stability, insight—and by their experience of life Intellectuality is, alas! a hindrance rather than a help The mother is bound after her pregnancy and delivery to be not her usual self, nor is she expected to acquire her normal emotional tone for six or eight weeks at least And no-one is likely to know really what hopes, joys, fears, or regrets have swayed her mind from the moment of conception, or whether the bonds of the family circle are such as will be strengthened or weakened by a family tragedy The community assumes that parents welcome the knowledge of a pregnancy, want babies, and love and cherish them from birth That some parents use contraceptives, successfully terminate pregnancies, or reject normal babies, is viewed with sympathy by society, which condemns infanticide and physical neglect, but recognises the instinct for rejection of parenthood in normal human nature

* * *

Faced with the certainty that the new baby is a mongol, what is the doctor to do? Although there is no way of altering the baby's condition, the doctor should work towards securing for the baby the care and protection which will allow him to develop to the limits of his capacity His needs in infancy are exactly the needs of the mentally normal baby physical care and satisfaction in an atmosphere of love and security To say that the mother at home and in her own family circle can provide these best, is to state an ideal It is not always the truth, and the ideal cannot always be achieved The mother and the father must be helped to accept the facts, helped to face them and their implications for the future, and helped to think out their plan for the care of the baby. The doctor must watch, so as to avoid, or at least lessen, the dangers to the family structure that arise while the parents are adjusting themselves to their experience. It is not the duty of the doctor, any more than it is the duty of the grandmother, to impose the solution. Nothing can alter the fact that the parents have a mongol baby. Whatever the fate of the baby, this fact will remain a fact for the rest of time, and the parents must make their plan with a sense of this perspective, leaving no place for regrets.

Once the diagnosis has been made, the possible lines of action are limited. The extremes are to keep the baby at home as a normal baby and to await developments, or to dismiss and reject him, to write him off as a "dead loss" and to find someone else to look after him—in a foster home, a nursery, or an institution. What is politely called euthanasia has no place in the care of the mongol baby and his family. Fostering, with a view to a later return home, or home care, with a view to admission to institution or residential school at some selected age, form intermediate compromises.

If the parents fail to notice that the baby is not normal (and this is usual even when parents include a doctor or a nurse) it falls to the lot of someone at some time to break the news. That person ought in the first instance to be a doctor, but whether he is family doctor, obstetrician, pædiatrician, or mental-health specialist depends upon who is available at the appropriate time, and is less important than the sort of person that he is. Let him be one who feels deeply about this problem, deeply enough even to pray before the interview and to weep afterwards. But the more deeply he feels, the more need is there for him to have thought deeply too. Whatever words are spoken, however many the talks, there are two moments in time to be bridged—the last in which the parents look with joy at their new baby and his future and the first when they know his tragedy in their hearts. The doctor who tells the parents that their baby is a mongol is performing a surgical operation without an anæsthetic. Only in the spirit induced by this sort of realisation should the doctor proceed with his hurtful and dangerous revelation. Upon his wisdom, upon his ability to see the situation as a whole, and upon the acceptability of his approach to the parents, may depend the future happiness and integrity of the affected family. That he imparts a bias of his own to the course of events is inevitable, but there is no place in all this for the doctor who always recommends the same solution, whether it be immediate separation or its opposite, or for the outpatient teaching session or a three minutes' chat in the doctor's surgery or the welfare clinic, nor for those to whom the consultation is no more than a rapid exercise in clinical diagnosis.

* * *

The parents should be encouraged to return for further talks at leisure, and in many cases a trained social worker or a sympathetic ward-sister, midwife, or health visitor can help. The list of things that the parents want to know varies little. Firstly, they need to believe the diagnosis and to accept the accomplished fact. "What will the child be like, will he live, how does it happen, why did it happen to us, can it or will it happen again, is there anything that we can do, is there anything that anyone can do?"

Acceptance and grieving form the first two stages of the healing process, and several expert opinions may be needed. Even then parents may appear not to accept the diagnosis. In some this is "putting a brave face on things", in others it is a dangerous delusion. The doctor who has made his point need not keep driving it home, and patients cannot be compelled to be cured of this or indeed of any delusion that does not lead to crime. Attempts to alter facts through quackery or spiritual healing under whatever banner are reasons more for pity than for interference.

A description of the life-history of the mongol baby and child is most important. Parents who lack direct experience of mental defect imagine what they do not know, and their own picture may be grotesque and terrifying. On the other hand, a visit to a home where there are many mongols is seldom wise. The suggestion to see some affected babies or children should be left to the parents to make, and tea with a high-grade case will show the best that can be hoped. About a quarter die in the first two years but many live on, especially when there is no complicating congenital disease. Resistance to simple infection is less than normal, but the parents should not be led to believe that their child will die young.

The ætiology of mongolism remains unknown. The great similarity between cases in different families, stocks and races, suggests that this is a human variant arising in between one and three of every thousand live births, commonest when the mother is over 40 years, but seen throughout the childbearing period. There is no known factor in the medical history or habits of the parents, and bad luck alone accounts for why this, which is a common risk to all humanity, should happen to one family rather than to another. Nothing in the parents' lives could produce it, nothing could have prevented it. Second cases do occur apart from twin births, and the parents must be so informed. The risk is not altered by the birth of a mongol, and is neither greater nor less at the next pregnancy. Nevertheless, with parents under 40 years the remark should be added that in real life second cases are exceptionally rare and the risk is well worth taking, especially when the mongol baby is the firstborn.

That there is no specific treatment must be admitted, but it is wrong to tell the parents that they can do nothing. Recent study of mentally defective children has shown the important part played in their lives by emotional disturbance. The emotional stability, the happiness and the general progress of the mongol baby is observably better when the family has accepted and loved the baby. This is no reflection on nursing care in foster homes and institutions, but simply means that the well-known fact that in the first five years home life is best for children applies to mongols as much as to their mentally normal siblings. When parents neither accept nor love the mongol, home care is not the best.

Certain other problems should be raised. The effect on the siblings of the addition of a mongol baby to the family has to be watched. The rest of the family usually takes the lead given by the parents, and if they adjust well to the situation little trouble results. From time to time the progress and behaviour of the siblings should be considered, and in some families the best interests of the normals may lead to a change of plan. This is the more likely if the mother gets into the habit of fostering her mongol at the expense of the siblings, and parents should be warned of the danger of the mother's neglecting her husband, her other children, or her home by concentrating too much on the mongol. It is wise for the parents to let near relations and close friends know that the baby is a mongol, that they have taken advice, and that the matter need not be referred to again'

* * *

The certainty of diagnosis that may follow the first look at the head of the part-delivered baby, referred to above, is responsible for the difficulty which surrounds the choice of time for revealing the fact to the parents There is room for difference of opinion and of practice If the baby is born at home, there is not the urgency that exists in hospital where the mother and baby normally go home on the tenth or the fourteenth day A routine method of handling is to be avoided, but on the whole I prefer to do no more than sow a seed of doubt in the parents' minds before they go home In this way the mother is given the chance to regain her emotional balance and to get really to know her baby I arrange to see them again at four or six weeks on the ground that the baby's general condition and progress is not absolutely satisfactory This conversation probably is wise, although at times it leads to a fuller revelation of the nature of the anxiety than was intended The parents must never be told positively that a mongol baby is normal, or confidence between doctor and patient is lost for ever Both parents must be seen at the second consultation, and at this or at the next, after a further one or two months, the full story should be told Unfortunately during these intervals a kind friend, neighbour, or relation, or another doctor or health visitor, may have alarmed the parents by some ill-advised remark, and it is wise for at least the medical and social workers to agree their plan

For the doctor to tell the father in the neonatal period with an injunction not to tell his wife is to put a dreadful strain on him, and reflects a singular idea of relations between husband and wife during their enjoyment of the new baby Often, however, the father is prepared to break the news to his wife and then to let the doctor explain the meaning of the diagnosis To tell the mother in the neonatal period before she has got to know her baby is again adding to the burden, unless the family situation is such that rejection of the baby seems likely to be the best solution When the parents have realised the diagnosis themselves, the decision is out of the doctor's hands One mother may utterly reject the baby in hospital and when the diagnosis is revealed in the first few days, she refuses to discuss it, seeming able to cut herself off successfully, though grieving privately Another, out of the fullness of her maternal spirit, cannot even for a moment consider a parting Such strong instinctive decisions are best left unchallenged

When the mother decides to keep the baby and to see how he gets on, she should be advised not to close her mind against his ever going away If he is very slow and limited the needs of the rest of the family may make it advisable, training and such schooling as is suitable may be possible only away from home, though this is less likely now that more occupation centres are opening Multiplication of instances is not the purpose of this article, each situation has its own characters and the best solution has to be worked out afresh each time The doctor can only help the parents to react well and try to persuade them that the birth of a mongol baby is not a defeat but a challenge to battle

Medicine and the Law

An Unstable Piano

A SCHOOL music-teacher employed by a local education authority had her foot crushed by a piano while moving it in the course of her teaching duties at a special school for crippled children, carried on at the Ascot Orthopædic Hospital under sections 62 and 63 of the National Health Service Act, 1946

The education authority provided teachers and the hospital provided accommodation and equipment, including the piano in question It had originally been fitted with four one-inch-diameter brass castors at each corner and two wheels in the centre which made it easy to move from ward to veranda and back again Some time before the accident the two centre wheels had been taken off and it became difficult to move The school headmaster repeatedly asked the hospital to replace the wheels On the date of the accident two hospital employees replaced the brass castors by four 3-inch-diameter wheel-castors in the hospital workshop, and took it back to the ward for the music lesson While the teacher was moving it back to its proper place in the ward it tipped over and injured her

She brought an action both against her employers (the education authority) and against the hospital management committee Mr Justice Stable awarded her £1013 against the hospital and dismissed her claim against her employers The hospital committee appealed

Lord Justice JENKINS said that this piano had had a long and blameless if somewhat nomadic career until its centre of gravity was raised by substitution of wheel-type castors for the old brass ones, thus making it top-heavy It was highly significant that this accident happened on the very day of the alteration If that was the cause of the accident, was there any breach of the duty owed by the hospital to the teacher? For the hospital it was argued that though the standard of care they owed her was higher than that of the donor of a gift to a donee, it was not so high as that of a manufacturer of goods who made and distributed them for reward His Lordship did not agree that this was like a case where the work was done gratuitously It was true that the piano belonged to the hospital and was lent without any payment to the education authority, but it was lent as part of the reciprocal arrangement between these two public bodies who together fulfilled the aims of education and medical treatment, and the duty of the hospital committee was to take reasonable care to see that the piano when fitted with the new castors should be reasonably safe No-one who had heard this case could fail to appreciate that upright pianos were liable to tip over, and the higher their centre of gravity the greater the propensity to tip over That was something which the hospital employees using reasonable care ought to have known and guarded against, and because they had not done so the hospital committee were vicariously liable Their appeal must be dismissed

As to whether the education authority was liable, this was not a case in which the employers provided plant in the shape of pianos or delegated their provision These were simply pianos which the authority's employees were permitted to use, and it could not be said that when the piano owners caused new wheels to be put on they were altering plant on behalf of the education authority True, the headmaster had asked for new wheels to be put on, but the education authority was not in control of the situation when it was done The accident happened before the employers even knew that the new wheels had been put on They could not in those circumstances be held liable The claim against them must be dismissed and the hospital committee should pay all the costs involved

Lord Justice HODSON and Lord Justice MORRIS agreed

JOHNSON *v* BERKSHIRE COUNTY COUNCIL AND THE WINDSOR GROUP HOSPITAL MANAGEMENT COMMITTEE *Court of Appeal* (Jenkins Hodson and Morris *L.JJ*) Dec 5 1957 Counsel and solicitors —F Beney Q C, and John Perrett (Gamlen, Bowerman and Forward for Lovegrove & Durant Windsor), E S Fay, Q C, and P M Blomefield (K Wormald), Montague Berryman, Q C, and E W Eveleigh (Berrymans)

In England Now

A Running Commentary by Peripatetic Correspondents

"IT is just like a sort of outpatient department" said my learned colleague. The juvenile court was in session and we were observing from the rear. The longer I watched, the more I saw his point. There had been those dreary queues for a start, in a large dim hall complete down to the small wooden table in one corner serving warm tea. Even the stray coppers weren't out of place. The chief consultants were pretty obvious behind the Bench, and their juniors presented clinical problems to them in a competent manner; the conclusions were probably not much more didactic than those at most teaching hospitals. Once the three chiefs even withdrew for a private consultation on a problem case. Most cases were appropriately returned home for domiciliary care under the direction of the, as it were, court general practitioner—the probation officer. Some were declared fit and discharged, and a few, after some headshaking and study of specialist reports (including, happily, psychiatric opinions), were sent for special inpatient care at a specified place.

These parallels seemed for the most part happy ones; a therapeutic approach is making some inroads on our punitive judicial system. But there were differences too. The Press isn't admitted to our ward rounds yet, and the magistrate still has a very strict set of rules to follow. We haven't had these since Ancient Egyptian times. No, it's not for nothing that we talk colloquially of beaks "dispensing justice", but with due humility I would like to suggest that the legal eagles tear one more leaf from our book and initiate a series of carefully controlled trials. Where prognosis is so obscure, how can one have much confidence in the treatment?

* * *

In our industrial part of the world, one of the interesting sights of road travel are the chemical tank wagons, bearing in large red letters such exciting notices as DANGER, *HIGHLY INFLAMMABLE*, STRONG CORROSIVE. As one follows them it is interesting to revive one's rusty chemistry and think out what first-aid treatment would be needed if an accident occurred. But in fact their presence seems to have a good effect on road manners. It is striking to watch how the motorist who has been trying to pass everyone suddenly slows down when he reads the red letters which say DANGER. EXPLOSIVE.

* * *

She was rushed into hospital as an emergency and spent an hour and a half on the operating-table that same night. Thirty-six hours later she was asking me if there was anything new in the headlines of the morning paper. Then for a week or more she was very weak, and behaved like an old, old lady. She soon picked up again and discussed with great interest her curious adventures in the half-world where she had searched in vain for death's door. Today I took her an offering of *Penguins*, ranging from D. H. Lawrence to the Venerable Bede, and she seized on them with delight. She handed me in exchange an article she had just written about Irish nurses, and asked me to get it typed and sent off to a Dublin paper. I looked through it later. The writing was shaky but the style was as lively as ever. There was only one slip; meaning to mention her birthday in 1958 she had put, "This has been written on my 158th birthday." If bodily wear and tear had not taken such a toll, it would be hard to find any logical reason why she should not still be writing on that anniversary. Mentally she's still in her forties, for all that she's turned ninety-five.

* * *

Since the man from the Ministry fell through the seat of our Senior Lecturer's chair some time ago the University has been turning over in its mind the desirability of allowing us to purchase some new chairs. The green light came last month and we have all been breathlessly awaiting the arrival of our new Professorial Chair. Our Professor is not a man to throw away an opportunity of getting a decent seat for the first time in his medical career, and he has been happily studying the form in several highly coloured catalogues. On sordid financial grounds he was regretfully forced to leave out of consideration the 'Floating-Eez' (at the touch of a button instantly assumes any angle desired, the business man's dream, guaranteed for a lifetime), and the Executive's Chair (padded arm-rests and stout swivel mechanism, a solid job) seemed lacking in dignity. The Director's Chair (with foam-rubber seat and adjustable back, in blue, red, or green) was rather better, but our efficient administrator, who rules us in æsthetic matters, maintained that in her opinion the rest of the furnishings were not suited to admixture with primary colours. There was accordingly little choice in the matter, and our accommodating Professor was driven to turn his mind to those chairs which were obtainable in pastel shades.

Fortunately the *Chairman's Chair* (with foam-rubber seat, stout swivel mechanism, *and* patent adjustable tilting mechanism) came in grey or black, and this morning a grey one arrived in the hall, swathed in paper padding and secured at all points with string. We tiptoed cautiously round it, exploring the foam rubber, and examining the tilting mechanism, rather enviously we watched it borne away into the professorial sanctum. But mark the sequel.

It appears that our Professor was hospitably entertaining the Vice-Chancellor at morning tea when he conceived the injudicious notion of putting the Chairman's Chair through its paces for the benefit of his guest. The first tentative circuit of the stout swivel caused him to crack his patella viciously on a totally unexpected corner of his desk, and while expressing himself with some force on this occurrence he unwisely leant backwards, thereby bringing into play the patent adjustable tilting mechanism to such effect that the whole chair, complete with Professor, overbalanced backwards, causing him to strike his head a savage blow on the corner of the bookcase. The Vice-Chancellor's tea spilled all over the desk and overflowed on to his trousers, and our gallant administrator, roused by the clatter, tripped over the mat on the way to the rescue and joined the chaos on the floor.

The Chairman's Chair is now in the possession of our stolid Senior Lecturer, and our Professor has taken over a wooden affair which used to stand in the room where the cleaners make their tea.

* * *

George has just returned from an important conference on burns, and is full of the missionary spirit. How not to get burned is the answer to the problem, and we have all been deprived of our nighties and given 'Proban' pyjamas. Every fireplace has its own particular fireguard, and at last I think we are going to get central heating. So far so good.

Grandpa had a stroke about four years ago, and is unsteady on his pins. We have had no trouble with him about nighties, because he was "modernised" in this respect many years ago. But he says he hopes we won't get rid of the coal fire before he "goes"—in his more pessimistic moments he hopes he "goes" before we get rid of the coal fire. Although the new fireguard is an elegant affair tastefully decorated with ivy leaves, he regards it with distaste, and says it keeps the heat away.

Yesterday when I came in the fireguard was in front of the piano and Grandpa was standing on the hearthstone, swaying gently, holding his cold left hand well into the chimney. We hope George's next conference will teach him not only how to handle burns, but how to handle Grandpa.

* * *

He is a short, hardy, unwashed Eskimo. When he came to England he could not give up entirely his former way of life. He sleeps in as cold a room as possible, in a truncated bed with a mattress that would produce bedsores on a rhinoceros. It is the nearest approach to the sleeping bench in his igloo. He needs hardly any blankets, even in the middle of the winter. He seldom baths and when he does he dries himself with a minute square, of towelling, for cloth is almost unobtainable in the Arctic. He never uses soap. Unfortunately, I have never met him and no-one in the university seems to know him, but I am sure of his existence. I stayed for two nights in his room while attending a meeting during the vacation.

Letters to the Editor

ANTIBIOTIC PROPHYLAXIS

SIR,—I am perturbed by your annotation of Jan 4 I have not had the opportunity to read the papers on which it is based, but nevertheless I wish to make a few comments

No formal definition of prophylaxis is given, but your meaning may be thought to be implicit in the second sentence "More often than not, the belief that antibiotics will prevent bacterial infections is unjustified" This is a view with which there can be no quarrel if the word "infections" implies, as I believe it should, invasion of patients, after they have started antibiotic treatment, by bacteria new to them or at least absent from them at the time when the treatment began Theoretically, however, it is surely possible that such invasion might be by organisms sensitive to the drug being used, and thus infection would not become clinically manifest and so might be said, in a sense, to have been prevented Hence it might be maintained that the statement "To use antibiotics for clean operations with the object of escaping wound sepsis or respiratory complications is a vain hope" is logically indefensible even if one cannot commend the practice it condemns But what is a clean operation? And does not prophylaxis in this context refer not to pure aseptic cleanliness, since that is unattainable, but rather to the control of those ineradicable organisms which lurk subclinically, waiting the opportunity afforded by operative trauma to spread and multiply?

From the remark "Among patients undergoing operations (for) resection of the colon with anastomosis, postoperative complications were as common in those who received antibiotics as in those who did not" it might be thought legitimate to infer that modern methods of preoperative preparation of the bowel by appropriate sulphonamide or antibiotic drugs are ineffective, this is contrary, I believe, to the majority opinion Equally, from the remark that "the incidence of wound infections after appendicectomy for acute-suppurative and acute gangrenous appendicitis was not reduced by parenteral tetracycline therapy" it might be assumed that there is no place in even the severest forms of acute appendicitis for antibiotic treatment, this too I believe to be at least debatable The evidence cited from the work of Petersdorf et al [1] appears to be unbalanced, for example, "No benefit was derived from the chemotherapy, on the contrary, patients given antibiotics were more susceptible to pneumonia, cutaneous staphylococcal infections, and bacteræmia due to gram-negative bacilli", and again "Routine administration of antibiotics did not prevent infection but often resulted in the infecting organism being a highly resistant proteus or pseudomonas", these statements seem to me to savour of special pleading, even of propaganda If this is so it might appear that you have spoiled an excellent case by biased overstatement and so failed to carry conviction in the entirely laudable aim of reducing the indiscriminate use of antibiotics

Falkirk RONALD G HENDERSON

*** Mr Henderson seems to disregard a danger which has long caused us concern—namely, that the widespread use of antibiotics will, by suppressing susceptible organisms, enable resistant strains to become dominant in an individual or in a community Even when there appears to be a good case for the use of antibiotics in prophylaxis—as in operations on the bowel—there still seems to be some doubt whether clear evidence of benefit can be produced We are impressed by the reports to which Pulaski [2] refers, and by the findings of Petersdorf et al [1], and we do not think we overemphasised their implications —ED L

SIR,—Dr Warren Crowe (Jan 18) wishes to express his full agreement with your conclusion (Jan 4) that antibiotics should not be used to prevent sepsis, but he still recommends the use of sulphonamides as prophylaxis Are sulphonamides in effective dose not more toxic and hazardous than penicillin? The question is not what one uses as a prophylactic agent but whether "chemoprophylaxis" is beneficial and safe There are certain clinical conditions, such as rheumatic fever, disabling chronic bronchial infection, and valvular heart-disease in a patient undergoing dental extraction, where chemoprophylaxis and antibiotic prophylaxis have proved their value To withhold prophylaxis is, at times, more dangerous, but I would certainly reiterate that the antibiotics should not be used indiscriminately to prevent sepsis, especially in the conditions mentioned in your annotation

Victoria Hospital,
Accrington, Lancs
S S JHAVERI

SIR,—I was interested to read Dr Warren Crowe's letter (Jan 18) and to learn that he had been using sulphonamides prophylactically in the treatment of arthritis accompanied by focal sepsis He mentions that he has had some success with a new form of sulphonamide drug, and in this connection I thought it might be of interest to record my experiences with sulphaethylthiadiazole ('Sethadil')

Although recently introduced to this country, it has been in regular use since 1940, first on the Continent and then in the United States A long-acting sulphonamide, it is of great value in the treatment of lobar pneumonia, bronchopneumonia, and similar infections, as it has a potency and antibacterial spectrum which is almost identical with that of sulphadiazine or sulphafurazole [3]

I have used a great number of sulphonamides, but have always been conscious of the risk that they might lead to renal complications However, the risks of this with sethadil seem to be fairly small According to Frisk [4] and Terrell [5] only 5–10% of the drug appearing in the blood or urine is acetylated Terrell also states that the free drug has a solubility of 300 mg per 100 ml in urine as acid as pH 5 3–5 6

Three doses in twenty-four hours completely controls the majority of infections for which I prescribe it, and after the initial three doses a day I find that often only two doses daily is sufficient

In my hands sethadil is as efficacious as the best of the currently available sulphonamides, and to my mind it can be used with far less worry about harmful renal effects As it is not necessary to insist on the patients taking more than the normal amount of fluid per day, I find this drug particularly useful in cardiac cases and also in children where it is always difficult to give large amounts of fluids

Although this drug is rather more expensive than most sulphonamides, by using it in an increasing proportion of patients, some of whom I would normally have treated with very much more expensive antibiotic preparations, I am quite sure that I have effected an appreciable reduction in my prescribing costs

PROBLEM FAMILIES

SIR,—Dr Scott reports in his "London survey" (Jan 25) that the incidence of problem families among the homeless is slightly more than four times as high as that ascertained by the public-health department among families living in their own homes In the television programme "Panorama" (Jan 6) the B B C showed briefly, but poignantly, the plight of families becoming homeless, and Lady Allen of Hurtwood writes [1] of her concern for the children who suffer with their parents in this way These reports are very disturbing

Dr Scott's survey demonstrates clearly that the "potential problem parent" does, by his own insufficiency, tend to become and remain homeless Careful consideration, however, of the many unavoidable reasons for which families become homeless points inescapably to the conclusion that the consequent suffering and degradation are sufficient to force even self-respecting families down into the "problem" group

The National Assistance Act, 1948, places a duty on the welfare department of the local authority to help any family whose homelessness can be said to be due to any circumstances which "could not reasonably have been foreseen"—fire, flood, and gale damage, for example, but not necessarily eviction in all its cruel and varied circumstance In contrast to the National Assistance Act, the Children Act, 1948, places a duty on the local authority, through the children's officer, never to refuse to receive into care any child destitute of shelter A cruel choice for parents separation and good material care for their child, or continuing a shared ordeal that only too often makes the child ill

Some brave and intelligent parents part temporarily with their children, and, competing with many other families in a similar plight, do find a new home, but, to quote Dr Scott again, "there seems to be a limit to the difficulties with which a stable but dull parent can compete, after which one further adversity will produce a complete breakdown in domestic management" Such parents give up their children and move into lodgings which, as childless people, they can find without difficulty Both may go out to work Why not? What hope have they of resuming normal home life? Probably they have another baby, and probably in consequence they are evicted from lodgings where they were accepted only because they were childless Meanwhile, the cost to national funds of maintaining their other children would be sufficient to pay the rent of an expensive family flat Some children thus grown up "in care" are placed in work with the help of the local authority Probably, by reason of parental deprivation, they are inadequate citizens. The cycle of problem families starts again

Some parents postpone the separation of their children from their mother by taking leave of each other The father goes into lodgings and has to pay for a landlady to look after him He has to pay also towards his wife and children's maintenance in either a homeless-family unit or short-stay accommodation The father must search for accommodation after the day's work and the mother during the day, taking with her in any weather whatever children they have, however young

It is at this point that I so often meet these families, referred from the casualty department, hungry and unwashed, the mother undeservedly drab, with broken shoes, and one or more of the children ill Usually with the children's illness the family's courage breaks, and they accept separation from their children for an indefinite time London is deservedly famous for its progressive and compassionate care of its children Dr Scott's survey shows again how wisely and how comprehensively London's children are known Nevertheless, in London and all up and down the country, these pitiful families move about without a plan, and by reason of just this aimless drifting they remain, for the ordinary citizen, out of sight Public concern, if informed, would surely give such support to the authorities which represent them that some way to surmount these almost insurmountable difficulties would be found

I must be one of very many people who would welcome such a public inquiry as Lady Allen suggests

Paddington Green Children's Hospital,
London, W 2 EILEEN SUMPTER

A FUNCTIONAL NECESSITY

SIR,—My letter of Jan 18 was concerned with the difficulties of securing the facts about consultant appointments and potential consultant vacancies I was not, therefore, as Lord Cottesloe suggests (Jan 25), "more concerned with attacking the Regional Board and its officers than attempting to deal with the extremely difficult problem of medical staffing" Indeed I have made considerable effort to get this problem fully ventilated, and I thought it helpful to your readers to quote the difficulty I had experienced in one regional-board area

I deliberately abbreviated my letter to you, Sir, and quoted only an extract from the written reply, because I am conscious of your need to economise in space I am, however, grateful to Lord Cottesloe for giving publicity to the questions I asked, but I must point out that he is in error in suggesting that he is quoting my request in full Nor would I wish to burden your readers with details of my efforts, commencing in 1956, to have this subject discussed in the duly appointed medical committee of the North West Metropolitan Regional Hospital Board

Without quoting the correspondence in full, perhaps I may be permitted to explain that I prefaced my nine questions with the words—"may the committee members please be furnished with the following information—or as much of it as can be made available —" Immediately following the questions my letter continued

> "I appreciate the fact that I am asking for a very large amount of information, some of which may not be readily available However, if we are to ensure proper staffing of our hospitals and also to solve the thorny senior registrar problem, I am quite sure that such details should be made available"

One is very glad to hear that a deputation visited the Ministry on Oct 16, 1957 Would it be too much to hope that the general purport of that deputation and its recommendations will be reported to the medical committee of the Board? Better still had the help and cooperation of that committee been sought first of all

I do most seriously submit that if regional boards do not make proper use of their medical advisory machinery it is virtually impossible for their professional staff to offer any concrete suggestions I feel sure that Lord Cottesloe will not be disappointed if he asks the help of his own medical committee, and his group medical advisory committees, in solving this otherwise intractable problem

Radlett, Herts R S MURLEY

SIR,—The whole consultant structure of the health service needs re-thinking Why is it not possible to have a pyramid of promotion in other hospitals similar to that in teaching hospitals? What is wanted is more jobs in the middle, not more jobs at the top It is not surprising that people fall off a ladder which has no rungs between the third and the sixth As long as the profession opposes the insertion of more rungs the senior registrars' present plight will remain

---

[1] *Times*, Jan 25

In a system of more gradual promotion, although full consultant status would be reached at a much later stage of their careers, there would be a much larger number of jobs to which senior registrars could progress In this hierarchy people could be paid according to the position they occupy and possibly according to their skill and experience, so that there would be no need for separate merit awards

It is improbable that those who initiated the system of merit awards for consultants ever imagined that private consultant practice would continue to the extent it has Merit awards, if such a system is justified at all, should only be paid to full-time consultants Private practice brings its own merit awards to those who deserve them

A system of awards for years of experience would be more appropriate to general practice, where payment is by a fixed capitation-rate Few general practitioners engaged in N H S work can devote much time to private practice, so that the only way they can improve their position is by taking on more patients This is of doubtful advantage to both doctor and patient If a system of awards could be coupled with a reduction in the maximum permitted number of patients, more young doctors would be enabled to enter practice and fewer middle-aged doctors would be killing themselves

Hatfield, Herts KENNETH C HUTCHIN

SIR,—As a newly appointed senior registrar I have followed the recent correspondence with interest

I am working in pathology because this is the job I want to do I would far rather be an assistant pathologist than a principal in general practice, and by temperament and training I would be better employed in my chosen specialty A point that deserves wider recognition is that the career structure most appropriate to general medicine and surgery is not necessarily ideal for other branches, and should not be imposed merely for uniformity

The essential feature of such a grade as you advocate is that it must be from here that promotions to consultant are made Having this vital safeguard, I should regard such a post not as another obstacle but as a welcome milestone I am only sorry that those who claim to represent me do not share my views

TRAINEE PATHOLOGIST

A NEW FORM OF CHLORAL HYDRATE

SIR,—Chloral hydrate is still regarded as one of the safest and most satisfactory hypnotics, but its wider use has been limited by its disagreeable taste and odour, and the absence of any tablet presentation of the drug

Recently we have investigated a new product, dichloralphenazone ('Welldorm') This substance is a loose molecular complex of chloral hydrate and phenazone, which breaks down readily in the gastric juices to release chloral hydrate Dichloralphenazone is available in tablet form and, in effect, provides a readily acceptable means of administering chloral hydrate

We have given it as a hypnotic to a wide variety of medical and surgical cases (over a hundred) Its effects have been a satisfactory sleep with no hangover In particular the elderly patients in the sixth and seventh decade did better with it than with barbiturates

Its toxicity appears to be comparable to that of chloral hydrate No gastric or intestinal irritation has been observed from its use, and it appears to be very safe compared with the barbiturates

A THEORY OF NERVE DEAFNESS

SIR,—Dr Fisch (Jan 18) points out that we have used the term "presbyacusia" to denote any loss of high-tone sensitivity, without restricting its use to loss associated with ageing I apologise if this should produce confusion, and it is certainly etymologically wrong Whether or not non-conductive deafness in the young should be regarded as essentially different from old-age non-conductive deafness seems to be an open question, many workers—for example, Wever—seem to regard old-age deafness as being due to a series of minor injuries of various kinds, having cumulative effects with time They would make no theoretical distinction Perhaps our use might be excused, as one does sometimes talk about premature ageing

We are very grateful for any data provided by clinicians, and especially cases of neural damage which do not produce primarily high-tone loss In our paper (Jan 11) we did not suggest that the supposed increase in neural "noise" would be the *sole* cause of high-tone deafness, indeed, we cited three references giving evidence of partial sectioning of the nerve producing this effect We did suggest that loss of channel capacity, due either to increased "noise" or to loss of functional fibres, seems to give primarily high-tone loss On the other hand, we do submit that perhaps *recruitment* may be found only in the presence of noise, be this neural or external in origin Any data bearing on this would be most welcome

The finding of Dr Fisch that some lesions in the organ of Corti improve sensitivity for high tones is extremely interesting If the lesions were restricted to the low-tone end, then we should not be surprised to find low-tone loss, and primarily low frequency impairment may be produced experimentally in the normal ear by masking with a narrow band of low-frequency noise If the low-frequency end of the organ of Corti were entirely destroyed, then the normal residual neural noise from this region should be eliminated This could reduce the total noise-masking, and thus conceivably improve high-tone discrimination Could this be a possible explanation? Clearly, to test this, data are needed concerning the locus of the lesions

It seems worth adding that the change in the slope of the curves given by our experiment seem to indicate recruitment By including points representing lower background intensities more information about the slope of these curves can be obtained This differential intensity threshold technique might perhaps be used to estimate degree of recruitment where loudness balance cannot be used, and this might be clinically useful where both ears are impaired

Psychological Laboratory,
Cambridge R L GREGORY

SIR,—I have read with interest the article by Mr Gregory and Miss Wallace (Jan 11)

They say that peak clipping has been tried in nerve deafness but with only slight improvement, and suggest that it may be necessary to filter out those frequencies where impairment is greatest to reduce stimulation

Dr Harvey Fletcher in his book *Speech and Hearing in Communication* had advocated that in cases of high-note loss the frequency response of a hearing-aid should have a slope equal to one-third of that caused by the nerve-deafness factor, and this in most cases means greatly increasing the amplification in the high notes Hearing-aid manufacturers have successfully fitted aids in many thousands of cases of nerve deafness, using automatic volume compression and tone control along the lines recommended by Dr Harvey Fletcher In our experience it is essential, in those cases where the audiogram shows little loss in the low frequencies, to cut out these low frequencies below about 1000 c.p s almost entirely This produces in many cases a striking increase in tolerance and intelligibility

There is a school of thought that believes that distortion may be introduced by high-frequency sound and that this may vitiate the improvement of the hearing given by the lower frequencies

In some of the current hearing-aids manufacturers have fitted a "high-note cut" to take care of this factor, if it exists Experience indicates that while this switch is helpful in reducing rubbing noise it has not so far been possible to detect any improvement in hearing or comfort following its use It may be that the factors of stimulation and distortion arise above the highest effective frequency of the hearing-aid—about 3500 c.p s

I think we may fairly claim to be able to help 90% of the nerve-deafness cases referred to us, but I feel that we are going to require much more information before we can help the remaining 10% if, in fact, they will ever be helped at all by hearing-aids

ENZYME TESTS FOR GLUCOSE

SIR,—The 'Clinistix' test has recently[1] been found to be highly specific for glucose in urine, none of a number of other sugars, when freed from glucose, giving a positive result at concentrations below 20%

The first comprehensive investigation[2] of the specificity of glucose oxidase (notatin) showed that modifications to C6 of the glucose molecule reduced the rate of oxidation to 2% or less of that of glucose Within the past year 2-deoxyglucose has been reported[3] to be a fairly good substrate for this enzyme, Sols has also demonstrated that glucosamine is slowly oxidised at pH 8 0 Another substrate, which is oxidised at about the same rate as 2-deoxyglucose is glucosone (2-oxo- or 2-hydroxy-glucose)

Although glucosone and 2-deoxyglucose react readily with clinistix and "Testape" under the conditions employed in urine testing there is no evidence that either sugar ever appears in urine 2-Deoxyglucose has not, to my knowledge, been reported as a natural product, the possible biological role of glucosone as a metabolic product of certain moulds, and as an intermediate in sugar interconversions, has been reviewed recently[4]

Both sugars are, however, being used increasingly in metabolic studies, and the limitation of manometric and colorimetric glucose assay using glucose oxidase should be kept in mind

STEPHEN BAYNE

SURGERY OR RADIUM FOR CANCER?

SIR,—We write to refute the suggestion made by Dr Lederman and his colleagues (Jan 18) that we in Birmingham wish to revive the old conflict between radiotherapy and surgery In the United Birmingham Hospitals patients with carcinoma of the cervix are seen at clinics at which both radiotherapy and gynæcology are represented Furthermore, many gynæcologists working in the area have actively participated in the formation of our treatment pattern

There may be little to choose between the results of radiotherapy alone, surgery alone, or the judicious combination of both methods when comparable series of clinically and technically operable cases are reviewed We agree that radiotherapy is the treatment of choice in all stage-2 cases where the parametrium is obviously involved with growth, in addition to stage-3 and stage-4 cases In many of the remaining stage-1 and stage-2 cases with gross obesity or other serious medical contra-indications, radiotherapy is clearly preferable In the residual group (stage 1 and stage 2) the lower morbidity from irradiation treatment must be weighed against the possible advantages which operation affords of the dissection of pelvic nodes and concealment of the diagnosis[1 2]

MANIPULATION FOR BACKACHE

SIR,—Knowing how successful manipulation can be, I admire Mr Bremner's efforts (Jan 4) Considering his cases were not chosen according to any definite diagnosis, his 10% success was good If a careful history of the onset of pain had been taken and manipulation had been carried out on those patients who had a sudden onset, the 10% might easily have risen to 50%

I do not agree with his using an anæsthetic, as, without the cooperation of the patient and a re-examination after each manœuvre, it is difficult, if not impossible, to tell whether an improvement has been obtained

Mr Thomas's reason (Jan 25) for manipulation shocks me To manipulate the spine as a "placebo", I hope will be deprecated by all his orthopædic colleagues

Mr Thomas mentions that he has never seen at operation a disc protrusion that could be reduced by manipulation That, of course, is as it should be Operation should be carried out only when the protrusion is irreducible by manipulation or traction, or if epidural local anæsthesia fails to bring relief

London, W 1

R BARBOR.

SIR,—Mr Thomas (Jan 25) has asked that very awkward question "What precisely do you attempt when you manipulate?" I agree with him that the glib answer about breaking down adhesions is improbable in this instance Personally I try to separate the joint surfaces to restore "joint play", and, if I am lucky, I break the vicious circle of pain—spasm—pain Treatment by rest, support, or the injection of a local anæsthetic may achieve the same result, but I have the "clinical impression" that manipulation is more effective

Is Mr Thomas convinced that the relief of pain which can follow manipulation of a hip is due to the breaking of adhesions?

London, W 1

W HARGRAVE-WILSON

SIR,—It has been said that there is no useful research without hypothesis Equally, no progress can be made unless one is prepared to revise the theoretical basis if the hypothesis does not fit the observed facts Nowhere does this seem more applicable at present than the prolapsed disc

The facts of the case appear to me that the disease commonly called prolapsed disc begins suddenly when the erector spinæ muscles are in tension and the spine is curved both forwards and laterally—for example, when the patient, with a bent back and straight legs, moves some heavy object (such as a shovelful of coal *or a* trunk) and passes it to one side

Another significant fact is that scores of unrecognised manipulators are making a laughing-stock of those orthopædic surgeons who believe in six weeks' rest or plaster jackets as a first ploy for conditions which lay manipulators, in spite of

---

[1] Bonney V *J Obstet Gynæc, Brit Emp* 1941, 48, 421
[2] Currie D *ibid* 1958, 64, 871

little medical knowledge and no radiographic control, can cure in a matter of minutes—using " cure " in the sense that the patient's complaint of pain and disability is removed completely

In the simple manipulation which appears to be used by some of these operators, and which I was shown by an orthopædic surgeon two years ago, one rotates the spine by gently persuading the bended knee down to the floor or bed on the opposite side, while the patient is lying relaxed, face upwards In many cases this produces an audible crack, similar in quality to the noise emitted by a forty-plus doing a knees-bend, suggesting tense tendon or muscle slipping over a bony prominence I do not see how this noise can be produced by a protrusion and restoration of the intervertebral disc This noise is accompanied by a sudden relaxation of tension in whatever muscle is being stretched (presumably the erector spinæ group), which can be felt quite distinctly with the guiding hand This is followed immediately by improved mobility and decrease in pain in most cases

Putting these two facts together, I would therefore suggest that the primary condition in a so-called " slipped disc " is a displacement of a muscle bundle or tendon in the erector spinæ, which, because of its displacement and discomfort, goes into spasm This spasm may result in the nearby vertebræ being pulled tightly together and thus mechanically producing disc protrusion I suggest that if this disc protrusion involves irreversible trauma to its retaining ligaments, then the protrusion can become permanent and can indeed be the chief source of further muscle spasm and disability—irreducible by manipulation and requiring spinal support or operation or both

By means of this simple manipulation (to be done afterwards as exercise by the patient along with the more usual hyperextension exercises), I find that my rate for referral to hospital of these unfortunate patients is reduced to about a tenth

Perhaps I may quote a typical case illustrating these points

A commercial traveller, aged 51, was driving one day to Glasgow and missed his footing when getting out of the car He felt the usual knife-like stab in the back and found getting about extremely painful and difficult At one of our larger teaching hospitals he was very thoroughly examined and investigated, but no very concrete effort at therapy was made, and, after spending all day in various departments of the hospital, he decided to come home After an agonising night, he came to my surgery, where, by this simple manipulation, he was greatly relieved, his only comment was " Why didn't somebody do that in Glasgow ? " He has had only minor trouble since, from slight recurrences, which he has been able to control and manage himself along the lines indicated

I strongly support, therefore, those who urge early manipulation for " slipped disc ", and hope that those in a position to do so will be able soon to put this on a sound theoretical basis

Workington, Cumberland R N R GRANT

TREATMENT OF MYXŒDEMA

SIR,—We were much interested in the article by Dr Gibson (Jan 18) on the control of the treatment of myxœdema by electrocardiography His statement that only patients " with a significantly lowered basal metabolic rate (B M R) are included " is however a little puzzling, since three of his patients, nos 3, 6, and 7, had B M R s of −6%, −3%, and −11% respectively

Dr Gibson does not tell us the standards or method used for determining the B M R , and we should be much interested to have this information Robertson and Reid [1] have shown that when the standards of Aub and DuBois [2] are used, the range of normal variation in Britain is 0 to −20%, and Robertson (personal communication) accepts as normal a variation of +15% to −15% for the British standards of Robertson and Reid [1]

Dr Gibson gives detailed information about two of these patients (nos 3 and 6) Both of these had undergone thyroidectomy In case 6, the B M R was found to be −3% seventy days after a *complete* thyroidectomy Means [3] says that complete athyreosis develops in about eighty days after acute withdrawal of thyroid hormone It is therefore rather surprising that this patient's B M R was as high as the value given by Dr Gibson

Case 3 had a subtotal thyroidectomy The clinical findings, apart from tiredness, do not suggest hypothyroidism, the B M R was −6% and the serum-cholesterol 235 mg per 100 ml The only clear support for the diagnosis in this case appears to be the electrocardiographic changes, presumed to be due to thyroid therapy These changes are of limited diagnostic use, Means [4] found that 7 out of 24 athyreotic patients retained their T-wave abnormality after specific treatment

M J SEAMAN

SYRINGES CLEAN OR STERILE ?

SIR,—Dr Morton (Jan 18) draws attention to the danger of a mass-inoculation technique in which one syringe is employed to inoculate many different people using a separate sterile needle for each patient It would be interesting to know whether the Medical Research Council is considering re-writing its official memorandum [5] which advocated this type of technique when mass inoculations have to be made, because most doctors who are giving subcutaneous and intramuscular inoculations ensure that the needle is not in a vein by pulling back the piston of the syringe after the needle has been inserted into the tissues It is curious that although nearly everyone is taught to do this it is not mentioned by the M R C and very few textbooks describe the technique

I have now read the leaflets issued with the poliomyelitis vaccine made by the Connaught Laboratories of Canada and Glaxo Laboratories and Messrs Burroughs, Wellcome of England The first two makers state that the vaccine should be given by intramuscular injections and the last intramuscularly or subcutaneously The Connaught Laboratories write " to avoid possible intravenous injection, pull back the plunger to make certain that no blood is withdrawn and then slowly inject the desired dose " This habit of preventing an intravenous injection, which I think any good doctor develops, and the use of the intramuscular route which Salaman et al [6] showed was liable to transmit virus hepatitis, indicate how unsafe a mass-inoculation technique, like those advocated by the M R C , could be The method of oil sterilisation [7] [8] would be very much safer as sterile syringes and needles are easily provided for every patient Very many children and some adults are now to receive poliomyelitis-vaccine inoculations, and I hope that a sterile syringe as well as a sterile needle will be provided for each patient

Children s Hospital,
Birmingham, 16

K B ROGERS,
Clinical Pathologist

SIR,—I am grateful to your correspondents for drawing my attention to the mistake in my letter of Jan 18 should have said that the syringes I described are sterilised in a hot-air oven

---

A local colleague, who uses similar syringe equipment, bought a second-hand electric oven, with a thermostat which maintains the temperature at 160°C, for about £12 This makes the cost of this technique of sterilisation comparable to the less efficient methods using water sterilisers

London, S.E.26 R N JACKSON

SPUTUM IN CHRONIC BRONCHITIS

SIR,—I was most interested to read the papers on this subject by Dr Brumfitt and his colleagues (Dec 28 and Jan 18), and it is gratifying to learn that conclusions based on sputum cultures are in general confirmed by their more elegant bronchoscopic swabbing technique I think, however, that two points require comment

The first concerns the site of infection in "bronchitis" In spite of the name, most of the inflammation, and presumably therefore the infection, is situated in the bronchioli and smallest bronchi, into which no swab can possibly penetrate[1] Bronchial swabbing, in the absence of infection of the larger bronchi, will only detect organisms deposited at the site by the passage over it of infected bronchiolar secretions, and consequently the recovery-rate of pathogens by this technique may well be *lower* than the actual incidence of these organisms in the bronchioles

Secondly, and more important from the practical standpoint, I feel that some qualification is required for Dr Brumfitt and Dr Willoughby's statement that "... the presence of pus was a poor guide to the presence of infective lesions of the bronchi" Presumably "infective lesions of the bronchi" in this context is synonymous with the presence of pathogens in the sputum This, however, is extremely variable from specimen to specimen in the individual patient, even when pus is present, and a true conclusion as to the pathogenic flora of any patient's sputum can only be drawn from examination of many specimens[2] Dr Brumfitt and his colleagues apparently obtained their results from the study of single specimens, and in these circumstances I would agree that the presence of pus does not necessarily indicate the presence of a pathogen. The correlation is much closer, however, if multiple specimens are examined, and our experience has been that in these circumstances the purulence of the sputum provides an excellent index of the presence of pathogens

Brompton London S W3 J ROBERT MAY

SUBURBAN NEUROSIS UP TO DATE

SIR,—In your leading article of Jan 18 you cite the results of a recent survey illustrating the much higher incidence of psychoneurotic illness among the rehoused population of a newly developed "out-county" housing estate to the north of London, compared with the "expected estate figure on a national basis" obtained by the Social Survey of Sickness

In discussing this higher incidence you point out that rehousing on such estates is partly determined by medical certification, but it can account for only a small part of the excessive neurotic illness encountered From this it is deduced that the determining factor is the absence of social amenities and the degree of social isolation engendered thereby It is true that many housing estates in this country, private as well as municipal, are without adequate social amenities, and many rehoused families on municipal estates must indeed find it difficult to accommodate themselves to the new and unfamiliar surroundings, so different from the more sociable atmosphere of their former environment. In the process of adaptation, casualties undoubtedly occur

It should be remembered, however, that a rehoused population on a municipal housing estate is a highly selected population. The criteria of selection may vary in detail with different authorities, but, in general, priority is given to families who are either without accommodation of their own or are living under socially or hygienically undesirable conditions It is among this section of the community, which is least successful in obtaining decent housing conditions by its own efforts, that one would expect a higher incidence of and tendency to psychoneurosis than among the community at large. I consider that this selective factor is important—no less perhaps than that of the paucity of social facilities on the estates to which these people have been moved

It would be interesting to compare the incidence of psychoneurosis among the population of municipal estates on the one hand and of comparable private-enterprise estates on the other There might well be a significant difference

DEATH FROM POSTMATURITY OR INDUCTION OF LABOUR?

SIR,—Mr Gibberd (Jan 11) accepts the dangers of postmaturity but wishes to convince us that the dangers of induction of labour are of the same order I should like to comment respectfully on two points in his article which I find unconvincing

If I understand his figures correctly, 1219 out of 8503 women (14 3%) at Queen Charlotte's Hospital reached forty-two weeks' gestation undelivered He therefore suggests that if forty-two weeks is taken as a reasonable "deadline", it would be necessary to induce labour in this number (1219) in order to avoid the hazards of postmaturity But he must surely agree that the label "forty-two weeks" in the hospital records often fails to stand scrutiny In a similar group of women reckoned overdue by the usual calculations, McKeown and Gibson[1] had to reject 172 out of 247 because of uncertainty concerning dates, bleeding in the early months, and a long or irregular cycle Further, it is generally believed that the multigravida is notably less liable to fœtal loss from postmaturity, though she is equally liable to be overdue Thus I think that many a clinician might induce labour in only a quarter of the total number suggested by Mr Gibberd, but out of that quarter he might hope to salvage (say) three-quarters of the possible loss from postmaturity

My second point of disagreement concerns that small hard core of primigravidæ who have been correctly assessed as postmature but, when induction has been tried, refuse stubbornly to budge Whether it be failure to start or an inert or disordered action after starting, I believe forty-eight hours to be the maximum safe period to allow following surgical induction in confirmed postmaturity I found this to be true in a previous series[2] and the 4 cases of stillbirth quoted in Mr Gibberd's article seem to emphasise this

No-one would dispute his point that the perfectly safe method of induction has not yet been described One could wish, too, to have some cast-iron test (e g, by paracentesis) to confirm one's clinical impression of postmaturity But even without these things, I think that better results can be obtained than those which follow a policy of strict non-interference, provided the clinician adopts a policy of selection and not routine induction, and provided he is prepared to undertake a number of cæsarean sections in the fœtal interest in a group with a high fœtal risk

Birmingham R B PARKER

SIR,—In discussing the management of established postmaturity Mr Gibberd has made a critical analysis of surgical induction of labour as a method of dealing with this undoubted problem

In table II of his article 4 stillbirths are recorded in 68 surgical inductions for postmaturity at Queen Charlotte's Hospital From these figures he concludes that induction is too dangerous to use in an attempt to reduce stillbirths due to postmaturity That this hazard need not be so great is, I think, shown by the accompanying table which I have compiled for surgical inductions of labour carried out at this hospital during the 3-year period 1955–57 when there were 1882 deliveries of viable infants The indication in each case was postmaturity alone

INDUCTION OF LABOUR BY ARTIFICIAL RUPTURE OF THE MEMBRANES FOR POSTMATURITY WITHOUT OTHER ABNORMALITY

Completed weeks of pregnancy	41	42	43	44 or more	Total
No of inductions	3	35	8	1	47
No of cæsarean sections after failure of induction	1	3	1	1	6
No of stillbirths	0	0	0	0	0

There were no stillbirths in these 47 inductions, but cæsarean section was resorted to more frequently than in Mr Gibberd's series This is presumably justifiable in view of his comments on the 4 stillbirths in his series

During the same period 1955–57 there were 5 stillbirths in this hospital attributed to postmaturity alone in patients who were not induced (fœtal loss 0 26%) These occurred despite the general policy to induce labour soon after 42 weeks where postmaturity seemed established It appears that induction with early resort to cæsarean section if the induction is unsuccessful can be safely used to save more babies but is not the complete answer to the problem

I wish to thank Mr Leslie Williams for permission to include in this letter the figures used above

UNUSUAL URINE PROTEIN IN MYELOMATOSIS

SIR,—We were interested in Mr Cummings' letter of Sept 21

Fifteen cases of myelomatosis were studied by paper electrophoresis of serum at the 2nd Clinic of Internal Medicine of Athens University (under the direction of Prof A Gouttas) In two cases, two pathological fractions were found instead of one

In the first case no pathological fractions were found in urine In the second case the only pathological fraction in urine corresponded to the slower and smaller pathological fraction of the serum

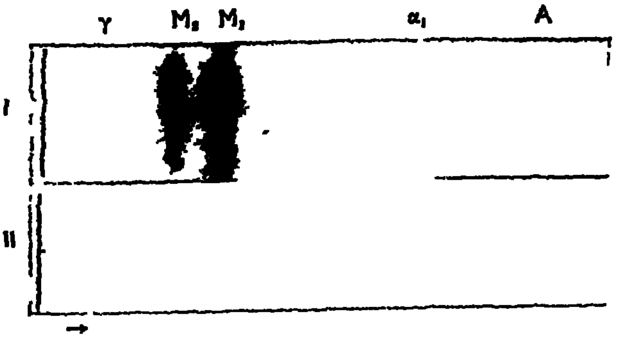

Fig 1—First case Electrophoretic patterns of serum (I) and urine (II). Buffer: veronal, pH 8·6. Paper Whatman no 1 Stain: Bromophenol blue.

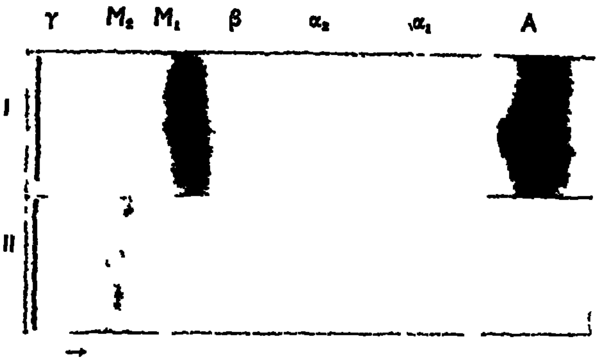

Fig 2—Second case Electrophoretic patterns of serum (I) and urine (II)

The existence in the serum of two pathological fractions, in some cases, may perhaps explain the presence in the urine of two pathological fractions It is strange that, in our two cases, electrophoresis of urine did not show the existence of the two pathological fractions

The pathological serum fraction in Mr Cummings' case may possibly have consisted of two fractions in close contact, which could be separated by the urine electrophoresis Perhaps electrophoresis of a highly diluted specimen of serum could demonstrate the existence of two fractions

WHERE DOES MEDICINE FIT IN ?

SIR,—Dr Manning[1] says that "the ever-increasing insecurity and instability of our world brings us, as doctors, face to face with people cracking and creaking under the strain"

As "the true answer" to this situation he suggests

> "It is only by putting man in his right place—by viewing him in perspective—that we shall realise just how small and insignificant his troubles are We have somehow to learn that we are not the centre of the Universe, that we are not different from other forms of life, and that we have not even full conscious control of our minds We have existed for only a very short time in a very small part of the Universe Though we happen to be the leading current form of life on our planet we are neither the biggest nor the most long-lived, and there is nothing except our pride to suggest that we are the ultimate in Evolution "

So this is what we are to tell those of our generation who are cracking under the strain of the insecurity and instability of Life "Fear not You are of no importance We live on a mere speck of the Universe We have been here a very short time compared with the amœbæ The elephants are far bigger than we are and live longer Please do not take yourself too seriously"

Is this sort of thing going to ease the pain of people racked by fears? Is it even rational? Is the significance of human life to be measured by the space and time in which it has been lived? If human life is the highest point in evolution, how can it have any but the shortest history?

To say that human life does not differ from any other form of life is a mere gratuitous pronouncement If we take into consideration the extent to which humans have outstripped other species, we are compelled (apart from religious faith) at least to reserve judgment on a question such as this If the Earth is but a tiny part of the Universe, is there any evidence whatever of life like ours in any other part of the Universe? If there is life like ours elsewhere, how does this make ours any less significant? Even if this sort of thinking were unassailable, how can it be considered helpful to a fear-ridden generation?

I quote the well-known statement of Jung

> "Among all my patients in the end half of life, that is to say over 35, there has not been one whose problem in the last resort was not one of finding a religious outlook on life It is safe to say that every one of

---

[1] *Lancet*, 1957, ii, 1274

them fell because he had lost that which the living religions of every age have given to their followers."

Would people haunted by fear and insecurity in the present age not be likely to benefit more from the Christian faith than from the "cosmology" suggested by Dr Manning? Surely, the claims of Christian teaching should be eagerly appraised. But Dr Manning does not give a moment's consideration to religious faith. He says that our generation has thrown it overboard and prescribes for the world's ills as if religion did not exist.

If Dr Manning and those who think like him have abandoned the Christian view of life, I hope that before doing so they gave to its credentials the consideration they demand. However, if after doing so they fail to accept the Christian faith, they should remember that there are very many who are deeply convinced that it represents the truth.

EARLY ADMISSION TO HOSPITAL OF MENTALLY DEFECTIVE BABIES

SIR,—Miss Adams' views[1] about the care of the mongol child are of interest, but we must remember that the life-span of a mongol can extend up to 72 years.

Formerly, I thought that the mongol child's best interests in early childhood were secured by keeping him at home. It is hard to realise that the infant mongol, with his healthy appearance and almost normal early development, will so deteriorate physically and mentally that at the age of 10 and afterwards he will have a mental age of 3–4. The decision must be made on the exclusive fact that the infant mongol can never become an independent person, mentally or economically. The female mongol is better adapted to home care than the male, and exceptions may be made to the general rule of institutional care in her case. As long as the home is intact all is well, but inevitably the parents die. At this late date in life custodial care in some form must be provided, involving a difficult adjustment period to a mode of life which she is not adapted to but which must be endured henceforth. Her greatest task is coping with her memories, which in the mongol are maintained at a high level.

The initial decision about the care of the mongol should not be influenced by emotional factors, theories, or personal prejudices. The mongol infant should not be used to satisfy a temporary intense maternal instinct provoked by the birth of a child. My opinion is that the normal-minded mother can use her reason if she unfortunately gives birth to a mongol child. She should not permit the development of a selfish frustration. Her husband should not be censured because he arranges for his mentally deficient baby to be admitted to an institution which can give him, as he develops, a happiness, a state of wellbeing, and a life with opportunities and an environment which no amount of wealth can give.

One of the major advantages which the mongol has in an institution is that he is living in an environment of equality of abilities, he has physical freedom and competitive opportunities in sports where handicaps are equalised, and is not frustrated by exhibitions of physical dexterity and mental normality. Individual and small-team competitive spirit is at a high level of enthusiasm. In a good institution he will not lose his family membership, because a competent social-service worker maintains and promotes family membership. This type of function by a social-service system is in direct contrast to the role which Miss Adams plays in the care of the mongol. I do not feel she is contributing anything constructive by increasing the frustration of the mother when she criticises the obstetrician and pædiatrician and condemns the husband for acting on the wisdom and long-term outlook of his competent advisers.

For over fifteen years I have treated in an endocrine clinic young mongol children from a hospital for the mentally retarded—but not on the premise that a hormonal deficiency is a primary ætiological factor. Thyroid is administered in the presence of clinical hypothyroidism, I find the mongol child more prone than the normal to the hypothyroid state.

I gave stilbœstrol to the males with sexual disturbances, and in a few patients who were strong-willed and would flee from protective observation, I insisted on protective institutional care.

Later I began early stilbœstrol therapy to inhibit gonad development. This prevented trouble when the patient found that the heavy dose of stilbœstrol required to suppress erections also produced breast development and deep pigmentation of the areola.

When I assumed my duties as consulting endocrinologist at the hospital for the mentally retarded in late 1955, I had my first opportunity of observing and studying 50 mongols whose ages ranged from infancy to 72 years, and some 25 patients who were receiving endocrine therapy at home. I had little doubt that the survey of 75 mongols showed that the endocrine-treated mongol from the institution was the happiest and best-established individual, because socially, mentally, physically, and occupationally he was the most advanced and accomplished, this applied to both sexes.

Philadelphia,
Pennsylvania.

CONGENITAL GALACTOSÆMIA AND MENTAL HEALTH

SIR,—Current textbooks of medicine and pædiatrics discuss congenital galactosæmia only briefly.[1 2] The incidence of congenital galactosæmia has not been established for lack of simple screening methods, but there is reason to suspect that the disease is not as rare as hitherto assumed. Awareness of the disease is essential for early diagnosis and treatment so that serious consequences may be prevented. Two illustrative cases are here reported.

A white boy, aged 13 weeks, was admitted to the Children's Hospital of Los Angeles with a diagnosis of galactosæmia made in another hospital by history and by the presence of reducing substance and albumin in the urine. At the age of 14 days the formula had been changed to one containing no milk. Subsequently, the infant ate well and gained steadily. The original diagnosis was confirmed by a galactose-tolerance test and by assay of red blood-cells for PGal uridyl transferase,[3] by newly developed specific methods.[4–6]

An older brother had been in an institution for feeble-minded children for several years. His I.Q. at 12 years of age was estimated at 11, and he could neither talk nor understand words addressed to him. Galactosæmia had never been suspected, though he had been examined at several clinics. His feeble-mindedness had been ascribed to erythroblastosis. It was known that he had bilateral cataracts. Blood was made available for study through the cooperation of the staff of the institution (Dixon State School, Dixon, Ill.), and we are especially grateful to Dr Abraham Gelperin. It revealed a striking defect of PGal uridyl transferase. The galactose-tolerance curve was also abnormal.

It seems highly probable that similar cases of unsuspected galactosæmia are present in mental institutions. Dr Robert Cooke, of Johns Hopkins University, has found three cases of galactosæmia in training-camps for retarded children (personal communication).

To clarify the incidence of the disease and to detect unknown cases for possible therapeutic benefit to them and certainly to their newborn siblings, large-scale screening seems advisable in institutions for mentally retarded children. The clinical indications for further screening might be based on the following

[5] Maxwell, E. S., Kalckar, H. M., Bynum, E. *ibid.* p. 478.
[6] Schwarz, V., Holzel, A., Komrower, G. M. *Lancet*, Jan. 4, 1958, p. 24.

(1) A family history of galactosæmia
(2) *A history of unexplained neonatal jaundice*
(3) Lenticular cataracts
(4) Enlarged liver
(5) Reducing substance in the urine which gives negative test on glucose test paper *

Confirmatory laboratory tests, such as the PGal uridyl transferase assay, could be used in suspicious cases Classical methods for identification of urinary reducing substances by chemical or chromatographic methods, and the galactose-tolerance test, might also be used

The method of enzyme assay may supplement or replace the galactose-tolerance test for several reasons Active indicator enzymes and coenzymes for testing have just recently become *commercially available* † *The enzyme assay is specific for* inherited galactosæmia [4] Moreover, galactose-tolerance testing may be contraindicated with neonatal jaundice, or with dehydration or hypoglycæmia Further, the task of investigating large numbers of cases by galactose-tolerance tests is formidable On the other hand, multiple enzyme assays may be done relatively rapidly by experienced technicians Four samples, including the internal standards, can readily be analysed in 2 hours The volume of blood required is small Blood from the umbilical cord can be used When necessary, arrangements should be made for collaboration with a laboratory doing the PGal uridyl transferase assay Red blood-cells can be obtained from centrifuged heparinised blood and stored *frozen until ready for shipment* [4]

If the transferase system is absent, complete investigation of the patient and his family is essential This should include slitlamp examination for cataracts, galactose-tolerance test, and PGal uridyl transferase assay of blood samples from other members of the family

It is not suggested that established brain damage can be improved This is a problem of the future Studies are at present under way of the effects of blocked galactose metabolism on the cells of microorganisms [7] Studies on cell and tissue cultures may shed further light on these problems

THE FALLACY OF THE FRACTURED CLAVICLE

SIR,—Mr Hicks (Jan 18) attempts to disprove what he considers to be a fallacy—namely, that the clavicle unites quickly and that this is promoted by incomplete immobilisation—by using another fallacy to do so It has long been recognised that clinical union of fractures often precedes radiographic union by a considerable period To use radiographic union as a standard is in itself a fallacy

ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH

DR DOUGLAS GUTHRIE, 21, Clarendon Crescent, Edinburgh, 4, writes

"I have been requested to collect material for a short history of the Royal Hospital for Sick Children, Edinburgh, to mark the centenary of the hospital which will be celebrated in 1960 If any of your readers have letters, documents, or photographs relating particularly to the earlier years of the hospital which they would allow me to utilise, I should be most grateful"

Parliament

Multiple Packs

IN an adjournment debate on Jan 23 Dr J DICKSON MABON reminded the House that when the new National Health Service charge of 1*s* for each item on an E C 10 form was discussed, the Health Ministers had agreed to consider introducing multiple packs for some chronic patients, including diabetic, tuberculous, colostomy, and cardiac cases The new charge had been in force since Dec 1, 1956, and so far only one new pack, for the treatment of boils and carbuncles, had been introduced If the Government was finding it difficult to get professional agreement on the contents of possible new packs, and Dr Mabon himself did not think that they were a good idea, should not other ways of helping the chronic sick be considered? Would it, for instance, be possible to allow a doctor to prepare his own multiple packs from an approved list of variants? Or could a doctor issue numbered registration cards to his chronic patients, so that prescriptions bearing these numbers could be freed of charges?

Mr J NIXON BROWNE, *the joint under-secretary of State for* Scotland, said that when the new charges were introduced ten multiple packs were already on the market Examples of these were the syringe and spare needles for diabetics, the vaporiser set for bronchitic patients, and the multiple pack dressings for minor wounds Since then the Health Departments had been trying to devise further packs for chronic patients, and in this they had had the help of the British Medical Association But the only new pack that they had been able to devise that seemed likely to benefit enough patients to make its production useful was a *larger pack of dressings for general* use This proposal was at present before the manufacturers, who were considering the production arrangements It was hoped that it would be in chemists' shops in 8–12 weeks' time

Everyone was disappointed that it had not proved possible to devise new packs The main difficulty was the varied needs of *different* patients Before a pack could usefully be manufactured and marketed, it must be established that the standard contents would be suitable for a reasonably large number of patients, otherwise it would be impossible for the manufacturers to support its production *Mr Nixon Browne also* thought that the patient would prefer to have the items he needed precisely prescribed for him separately, rather than be given a standard pack *which did not* really meet his particular needs

Health of Office-workers

ON Jan 24 Mr VICTOR YATES *introduced as a private* member's measure the Offices Regulation Bill, which followed many of the recommendations of the Gowers report Besides empowering the *Home Secretary* to lay down minimum standards in every office for "structure, arrangement and operation" for the protection of the health, safety, and welfare of employees, the Bill also made special provisions for the fencing of dangerous machinery, the prevention of injury from electrical equipment, protection against the lifting of excessive weights, and the prohibition of the employment of women before and after childbirth

Mr DAVID RENTON, joint under-secretary of State for the Home Department, said that the Government supported the objects of the Bill But a measure to organise *conditions* in all offices was bound to be a major administrative and legislative exercise which could only follow consultation between Government departments, local and other public authorities, and

† Obtainable from Sigma Chemical Company, St. Louis, Missouri

7 Kurahashi, K., Wahba, A. Unpublished studies

representatives of trades unions and employers' organisations Decisions would have to be taken at the highest level on methods of enforcement, administration, and cost It was therefore doubtful whether a private member's Bill would ever be suitable for this purpose. He agreed that private members' Bills had sometimes been successfully taken over by the Government, but such a procedure would not be suitable for this Bill because the necessary preliminary consultations had not taken place and because it left too many important questions unresolved But he wished to leave the House in no doubt that the Government accepted the need for the Bill and the principles which it covered A heavy programme had been announced for this session and it would be unwise to rush into legislation of this kind without adequate preparation and consultations

QUESTION TIME

Whitley Claim

Mr R J **Mellish** asked the Prime Minister if he would make a statement on his meeting with staff side Whitley Council (Hospital Staffs) held on Dec 23

Mr R A **Butler** I have been asked to reply Having heard the considerations put forward by the deputation from the staff side of the General Council of the Whitley Councils for the Health Services (Great Britain), on which the National and Local Government Officers Association was represented, the Prime Minister explained that the decision announced by the Health Ministers in relation to the pay of the administrative and clerical staff had been taken in the light of the need to maintain the position and purchasing power of the pound, and that the 3% increase could not be granted at the present time He agreed that the Whitley machinery in the health services needed to be reviewed, and said that in this context the points made by the deputation would be borne closely in mind

Mr **Aneurin Bevan** When the National Health Service was established and the Whitley machinery itself formed part of it, it was obvious that final responsibility must rest with the House of Commons because these were very large sums of money Is it not a fact that it was then hoped that the Whitley machinery would stand as a shield between the House of Commons and the workers involved? Would it not be wholly undesirable that large bodies of workers should be brought into conflict with the House of Commons and that wage-rates should be discussed on the floor of the House? If the Government persist in their attitude, would it not be necessary for us to have debates on wage-rates and to compare conditions with other conditions enjoyed by other members of the community, in which case, could it not easily happen that large bodies of workers in the country would come into conflict with the House of Commons and strike against the House of Commons?

Mr **Butler** One has to strike a balance between the sovereign power of the House of Commons and Parliament, the desire of hon Members to discuss matters of vital importance here, and the importance of preserving what the right hon Gentleman described as the shield of the Whitley machinery As I understand it, since the beginning of the National Health Service it has always been accepted that Whitley agreements must be in the form of recommendations to Ministers As Ministers are responsible to Parliament it is impossible to keep Parliament away from these problems I would add that the Minister of Health has deliberately said that he has undertaken to look at the Whitley aspect of this problem

Mr W W **Hamilton** asked the Secretary of State for Scotland if he had any further statement to make on the proposed pay increase for clerical staff within the National Health Service Mr J N **Browne** replied The staff side of the Administrative and Clerical Staffs Whitley Council lodged a claim on Jan 3 for a 5% increase to staffs on salaries up to £1200 per annum The council has agreed to defer consideration of the claim until Feb 12

Obituary

JOHN HUMPHREY THORNTON CHALLIS

M.R.C.S., F.F.A.R.C.S., D.A

Dr John Challis, senior anæsthetist to the London Hospital, died on Jan 21

Born in 1896, he was the son of the late Dr H T Challis He was educated at the City of London School and entered the London Hospital in 1913 As a lieutenant in the Royal Field Artillery (T.A) he left the hospital at the outbreak of the first world war and served in France and in many parts of the Middle East. Later he went with the British Forces to Russia, and afterwards to Ireland where he remained until 1922 Then, after 8 years of very varied and active service as a combatant, he re-entered The London and qualified in 1925 He spent the next 2 years in general house-appointments, alternating with periods in his father's general practice, before he began his career in anæsthetics In 1927 he became resident anæsthetist at The London and in 1931 was elected assistant anæsthetist to the hospital

His ability and capacity for work quickly won him a high reputation in his specialty, and his services were greatly in demand. In the '30s he visited America to study the new procedures, especially tracheal intubation, which he was introducing into this country He was elected also to the staff of many other hospitals, including the Southend-on-Sea General, King George V Hospital at Ilford, the Royal National Throat, Nose and Ear Hospital, Plaistow Maternity, Thorpe Coombe Maternity, and the Jubilee Hospital at Woodford Green.

In 1939, despite his many appointments, his age, and his long previous service, he transferred the commission he still retained in the Royal Artillery to the R A.M C , and following the outbreak of war went to France again. With the rank of major he was in command of a mobile neurosurgical unit. With this he retreated towards Dunkirk and with its many hundreds of wounded he was taken prisoner

The privations of the succeeding years undermined his health and though repatriated in 1943 he never fully recovered Debarred from most of the active pursuits, such as riding, which he had previously enjoyed, he never allowed disability to interfere with his work. He continued to contribute to medical literature and in 1947–48 was president of the anæsthetics section of the Royal Society of Medicine

Ten years ago he became senior anæsthetist to the London Hospital Of his work there J R E writes

Perhaps Challis's greatest achievement lies in his building up his department to meet the advances and increased demands of the last decade This he did with the efficiency and quietness that were so characteristic Always maintaining the highest standard of work, always cheerful, always kind and courteous, he was universally liked and respected His influence reached well beyond his own department, and his students rightly felt that from him they learned "doctoring" as well as anæsthetics He was an extremely modest man and spoke very little of his remarkably wide experience, but in his daily work and life he set an example of integrity and selflessness which could not be hidden Above all he set an example of courage Not even to those who knew him most closely did he ever complain about the cruel legacy of the last war, the disability of which inexorably increased His triumph over this affliction was not the least of his many achievements, but it was one he shared with his wonderfully happy and united family, his wife Dr Margaret Challis and their three daughters

His memory will last long in his hospital and will challenge and inspire many to aim at the high standard of service which he himself both set and bravely reached.

DOROTHY KIRBY PATERSON

M B Lond , D P H

Dr Dorothy Paterson, school medical officer and assistant medical officer for Southend-on-Sea, died at her home in Thorpe Bay on Jan 9 at the age of 43 From the Ilford County Girls' High School she won scholarships to the London School of Medicine for Women, and she qualified from the Royal Free Hospital in 1939 In 1948 she took the D P H and in the same year took up her appointment at Southend

J S L writes

Dr Paterson's duties were mainly connected with schools and schoolchildren, but she was also medical officer to the council's residential institutions for children and medical officer to the infant-welfare centre Her association with the nursery and children's homes was probably the most completely satisfying of all her professional activities , but her concern for the children went beyond their medical care, for she came to know some of them very well and interested her friends in the activities of the Homes To a wide clinical experience and excellent judgment there was added an instinctive and sympathetic understanding of children, who quickly gave her their trust As a colleague she was always helpful, self-effacing, and utterly reliable In recent months her friends noted with pleasure some lessening of her shy reserve and an enhancement of her natural serenity

Sir THOMAS DUNHILL

J W L writes

No account of the career of the late *Sir Thomas Dunhill* would be complete without mention of the fact that it was he who in 1932 founded the New End Hospital thyroid unit which, from small beginnings, has through the years increased out of all knowledge, not only in the number of patients treated, the size of its premises, its equipment, and the scope of its activities, but also in its reputation, which is nowadays not confined to the British Isles When in 1955 he watched the Duke of Edinburgh open a self-contained, readapted wing of the hospital, to be devoted entirely to the work of the thyroid clinic and department of endocrinology, he must, one thinks, have experienced a feeling of intense satisfaction in the knowledge that here, too, he had not laboured in vain

Notes and News

A NEW AFRICAN MEDICAL SCHOOL ?

EIGHTEEN months ago a committee, with Mr Leslie Farrer-Brown as chairman, was formed to advise the University College of Rhodesia and Nyasaland on whether it should set up a medical school Last April the committee visited the three territories of the Federation, and now they have presented their first report, which the college is considering

They think that " the Federation will fall behind other communities comparable in area, population and growth unless it includes a medical school in its plans ", and they recommend that such a school should be established soon, because of the need for the local training of doctors and of the need and opportunity for research They regard it as axiomatic that the school should provide " a course of a university standard leading to a qualification which is registrable by the General Medical Council " Believing that a medical school should be integrated as closely as possible with the university of which it is part, they reject the claims of Bulawayo to be the most suitable place for the main teaching hospital, and propose instead that it should be formed round the nucleus of the new African hospital 7 miles from Salisbury Except when doing their medical or surgical clerking, the students should " live and study and play alongside the students of other faculties " The estimated cost of creating a medical school of the type recommended, with an intake of 25 students a year, is £1 million, and the annual expenditure would be £250,000

Besides the chairman, the committee consists of Prof W Melville Arnott, Prof T H Davey, Prof P B Medawar, Prof R Milnes Walker, Prof A D M Greenfield, and Dr Honor Smith

MAKERERE COLLEGE

FOR the University College of East Africa an important event of the last academic year[1] was that the General Medical Council recognised its licentiateship in medicine and surgery—the only African qualification so far recognised by the Council except those granted in the Union of South Africa

In the medical faculty much of the teaching is done by members of the Government Medical Service who are on the staff of the Mulago Hospital and act as part-time lecturers and collaborators in research, and sit on the faculty board Besides their teaching and heavy clinical work, the staff have found time for a great deal of research Some idea of the hard conditions in which this sometimes has to be done is given in the report of the department of obstetrics and gynæcology

> " The maternity department has been greatly overcrowded this past year, making teaching difficult, as mothers and babies often have to be discharged 24 hours after delivery through lack of beds Patients are often nursed and sometimes delivered on the floor "

An echoing theme in accounts of African medicine is the want of doctors The department of surgery organised no postgraduate course because the lack of doctors prevented the Government from releasing enough from duty to warrant a formal course In the department of obstetrics, " leave periods mean very heavy work for the staff left behind it makes it very difficult to find time for adequate research " The department of pathology was forced to reduce the number of formal laboratory classes because " Government pathologists have simply not got the time to assist in teaching large laboratory classes " It is indeed heartening that, for all these handicaps, Makerere College is successfully training the African doctors who will eventually fill these great gaps

WORLD HEALTH ORGANISATION

THE Executive Board, meeting in Geneva, has decided to ask the Director-General to study the possibility of including sports medicine in the programme of W H O Proposing this, the four Scandinavian countries pointed out that our way of life, as machines are used more and more, leads to a lessening of physical activity, and coronary-artery disease, for instance, is commoner in those whose occupations involve less physical work. Sports are increasingly practised, " as they satisfy man's apparently instinctive urge for motion", in turn they invite consideration of their effects on health and longevity, the prevention of accidents, and their mental-health aspects The proposal urges W H.O to take the lead in sports medicine

---

[1] Makerere College the University College of East Africa Report for the year 1956–57 Obtainable from P O Box 262, Kampala Uganda

In the yaws eradication campaign, half the 200 million people exposed to the disease will have been examined, and 25 million treated with penicillin, by the end of this year Most of the remaining 100 million live in Africa, where populations are scattered and there is not much money, the campaign is expected to take about ten years What can be done is shown by the fall in the prevalence of yaws, since the campaign began, in Western Samoa (from 11% to 0 04%) and Haiti (from 36 5% to 0 57%)

APPROVED NAMES FOR DRUGS

THE British Pharmacopœia Commission has issued the following new supplementary list of approved names

Approved name	*Other names*
*Alphacetylmethadol	α-3-Acetoxy-6-dimethylamino-4 4-diphenylheptane *O*-Acetate of α-6-dimethylamino-4 4-diphenylheptan-3-ol
*Alphamethadol	α-6-Dimethylamino-4 4-diphenylheptan-3-ol
Azacyclonol	Diphenyl-(4-piperidyl)methanol Frenquel is the hydrochloride
*Betacetylmethadol	β-3-Acetoxy-6-dimethylamino-4 4-diphenylheptane *O*-Acetate of β-6-dimethylamino-4 4-diphenylheptan-3-ol
*Betamethadol	β-6-Dimethylamino-4 4-diphenylheptan-3-ol
†Bromodiphenhydramine	2-(4-Bromodiphenylmethoxy) ethyldimethylamine 4-Bromo-α-phenylbenzyl 2-dimethylaminoethyl ether Ambodryl
Chlorothiazide	6-Chloro-7-sulphamoylbenzo-1 2 4-thiadiazine 1 1-dioxide Chlotride, Diuril, Saluric
Choline Theophyllinate	Choline salt of theophylline Choledyl
Cyclopregnol	6β-Hydroxy-3 5-*cyclo*pregnan-20-one Neurosterone
Cycloserine	*D*-4-Aminoisoxazolid-3-one Seromycin
Deserpidine	11-Demethoxyreserpine Harmonyl
*Desomorphine	Dihydrodeoxymorphine
*‡Dimepheptanol	6-Dimethylamino-4 4-diphenylheptan-3-ol Methadol
Diphenylpyraline	Diphenylmethyl 1-methyl-4-piperidyl ether Histryl is the hydrochloride
*Etoxeridine	Ethyl 1-[2-(2-hydroxyethoxy)ethyl]-4-phenylpiperidine-4-carboxylate
Hexocyclium Methylsulphate	1-(2-*cyclo*Hexyl-2-hydroxyphenethyl)-4 4-dimethylpiperazinium methylsulphate Tral
Hydromorphone	Dihydromorphinone Dilaudid is the hydrochloride
Mannomustine	1 6-Di-(2-chloroethylamino)-1 6-dideoxy-*D*-mannitol Degranol is the dihydrochloride
*Methyldesorphine	6-Methyl-Δ^6-deoxymorphine
*Metopon	Dihydromethylmorphinone
*Myrophine	Myristyl ester of benzylmorphine
Nandrolone	17β-Hydroxy-19-norandrost-4-en-3-one 19-Norandrostenolone 17β-Hydroxyoestr-4-en-3-one Durabolin is the phenylpropionate
Oxycodone	Dihydrohydroxycodeinone Eucodal is the hydrochloride
*Oxymorphone	Dihydrohydroxymorphinone
Promazine	10-(3-Dimethylaminopropyl)phenothiazine Sparine is the hydrochloride
Proquamezine	10-(2 3-Bisdimethylaminopropyl)phenothiazine
Thalidomide	α-Phthalimidoglutarimide Distaval
Thebacon	Acetyldihydrocodeinone
*Trimeperidine	1 2 5-Trimethyl-4-phenyl-4-propionyloxypiperidine

University of Aberdeen

Dr E Maurice Backett, senior lecturer in social medicine at Guy's Hospital and at the London School of Hygiene and Tropical Medicine, has been appointed to the new chair of social medicine at Aberdeen. He is expected to take up his appointment in October

Dr Backett, who is a bachelor of medicine and science of the University of London, qualified from Westminster Hospital in 1944 After working on the research staff of the Air Ministry, he held a Nuffield fellowship in social medicine and later joined the Medical Research Council's social medicine research unit. Before taking up his present post he was lecturer in social medicine in the Queen's University, Belfast. He took the M.R.C.P. in 1950 and the D.P.H. in 1955 His published work includes studies of general practice, of the social care of deaf mutes, and of the social pattern associated with the spread of infection by poliovirus More recently, with other members of the unit, he has been inquiring into the incidence of road accidents among children and of coronary disease in doctors

University of Edinburgh

Dr W L M Perry, director of the Department of Biological Standards at the National Institute for Medical Research, London, has been appointed to the chair of materia medica in succession to Prof J H Gaddum who is retiring

Dr Perry qualified from the University of St. Andrews in 1943 and took the degree of M.D five years later After holding house-appointments at the Royal Infirmary, Dundee, he became a medical officer in the Colonial Medical Service, and was stationed in Nigeria. He joined the scientific staff of the Medical Research Council in 1947 His research has been mainly concerned with the autonomic nervous system. In 1952 he was appointed to his present post, in which he has of late years been closely concerned with controlling and testing the British poliomyelitis vaccines He was appointed O.B.E. in 1957

The university court has announced that Sir Stanley Davidson will retire from the chair of medicine at the end of March, 1959

Dr A. A Shivas has been appointed lecturer in the department of pathology, and Dr J F Lamb lecturer, and Dr M Jacobsen assistant, in the department of veterinary physiology

National Institute for Medical Research, London

Dr D G Evans has been appointed director of the Department of Biological Standards at the institute in succession to Dr W L M. Perry, whose appointment to a university chair is announced above. At present Dr Evans is head of the control laboratory of the department.

University of Adelaide

Mr R. P Jepson, professor of surgery in the University of Sheffield, has been appointed to the chair of surgery

Royal College of Physicians of London

On Thursday, Feb 13, at 5 P.M at the college, Pall Mall East, S W 1, Dr A. L Cochrane will give the Marc Daniels lecture. His subject will be the meaning of the X-ray classification of coalworkers' pneumoconiosis

Reticuloendothelial Society

The second symposium of this society will be held in Rapallo, Italy, from Aug 29 to 31

It is intended to discuss the subject under three main headings the reticuloendothelial system and steroids, the reticuloendothelial system and immunity, including antibody immunity and properdin, and tumour immunity, and the reticuloendothelial system and radiation. Proposed titles of papers should be sent, with a brief summary in English, before March 15, to Dr Alberto Marmont (Clinica Medica Universitaria, Viale Benedetto XV, Genoa, Italy), who will notify accepted speakers

---

* Narcotic substances which fall under International Conventions and are not available as therapeutic agents

† Replaces the approved name bromazine from May 1, 1958

‡ Replaces the approved name methadol.

Royal College of Obstetricians and Gynæcologists

At the meeting of council held on Jan 25, with Prof Andrew Claye, the president, in the chair, the following were elected to the membership

Vijayaratnam Balachandran, Bholanath Banerji, S K Basu, F X Bencini, Olga Bolitho, R T Booth, Carolina A Braga, A F Bushby, A S F Butcher, D P Das, F J De Maria, R E F Devitt, P H Drake, I MacD Duthie Mary G Eldridge, Denys V I Fairweather, F G Feinstein, N K Ghose, P R G Gordon, H M Gough, J L Hanington, G H Harris, J C Hartgill, C. H Hodge, Helena E Hughes, T R Hunt, A H John, Satyadev Khanna, Herbert Kramer, Dorothy K C Kwan, D J Mackay, Patricia C Mackay, Sheila A Martyn, Gillian G Matthews, R J Mitchell, A K Mukherjee, Jean M North, Joan North, O K Ogan, W H Patterson, P A Rachow, Krishna Sankari, Bernard Shieff, Ma Khin Si, Margaret L Smith, I H F Swain, Mary A T Tolley, R D Upton, Beoin Cleote Uys, A J Van Amerongen, J A Verzin, D W Warrell, James Willocks

The Human Brain

On Feb 6, 12, and 18 at 5 15 P M lectures on this subject will be given at Bedford College, Regent's Park, London, N W 1 The speakers will be Prof J Z Young, Dr D M. MacKay, and Dr W Grey Walter

Faculty of Homœopathy

At a meeting of this faculty to be held at the Royal London Homœopathic Hospital, Great Ormond Street, W C 1, on Thursday, Feb 6, at 5 P M, Dr Alva Benjamin will speak on the medical profession's responsibility for the health of the community

North of England Obstetrical and Gynæcological Society

The following officers have been elected for this society for 1958

President, Dr E A Gerrard, vice-presidents, Miss M Evans, Mr C J K Hamilton, Mr G W Theobald, Prof C S Russell, and Mr F J Burke, hon treasurer, Mr C H Walsh, hon general secretary, Miss E Mills, hon reporting secretary, Miss U M Lister

Child and Family Psychiatry

The department of child and family psychiatry of the Ipswich and East Suffolk Hospital is holding a course on this subject from March 24 to 28

The course is open to doctors and places will be allocated in order of application to 11, Fore Street, Ipswich

Work in Compressed Air

The Work in Compressed Air Regulations, published last August in draft form (see *Lancet*, 1957, ii, 333), are to come into operation on April 21

Liverpool University Medical Students' Society

The annual dinner for past and present members of this society will be held at the Mecca Sefton House, Liverpool, on Feb 6 Dr E T Baker-Bates will be in the chair and the guest of honour will be Dr T Leslie Dowell Tickets (25*s*) may be had from the medical dinner secretary, Medical School, University, Liverpool, 3

Medical Art Society

This society will hold its annual exhibition at Walker's Galleries, 118, New Bond Street, London, W 1, from Thursday, Feb 13, to Wednesday, March 5

International Collegium for Neuro-Psychopharmacology

The first of these international symposia will be held in Rome from Sept 9 to 12 Those interested in presenting papers are asked to send a 250-word abstract before March 31 to Dr P B Bradley, department of experimental psychiatry, Medical School, Birmingham, 15

The Hurt Mind

Four of the B B C television programmes on mental health which were transmitted under this general title last year, are now available in 16 mm film form (*Put Away*, 5 reels, £1 5*s* 46 minutes, *Break-down*, 3 reels, 15*s* 29 minutes, *Psychological Treatment*, 3 reels, 15*s* 30 minutes, and *Physical Treatment*, 3 reels, 15*s* 33 minutes) They can be hired from the Central Film Library, Government Building, Bromyard Avenue, Acton, London, W 3

Dr J C. M Matheson, principal medical officer at Brixton Prison is retiring after 28 years in the Prison Service

Diary of the Week

FEB 2 TO 8

Monday, 3rd

CORRIGENDUM *Research on Schistosomians in China*—In the second paragraph of a note describing the work of Prof C P Mao (*Lancet*, 1957, ii, 498) lines 5, 6, and 7 up to "fertiliser" should have been omitted, and the following words should have appeared at the end of the paragraph "Schistosome eggs contained in the night-soil are destroyed either by composting or by storage, especially when calcium cyanamide (which is a useful fertiliser) or urine (which produces ammonia) is mixed with the fæces"

The Lancet · Saturday 8 February 1958

RESULTS OF NYLON-DARN REPAIRS OF HERNIÆ

G E MOLONEY
M.B N.Z., F.R.C.S.E., M.R.C.P
ASSISTANT SURGEON, RADCLIFFE INFIRMARY, OXFORD

EVERY medical-school boy knows what to do to cure rupture, even though he may become a medical statistician or a member of parliament. We had hints on sacs and their coverings in our pregestational preclinical period, we were weaned into clinical surgery by the study of lumps in the groins, a part of every surgical childhood is assisting at a hernia operation, and much of the puberty of an operating surgeon is passed in attempts to contain the results of Nature's foibles and caprices in the inguinal region. Yet, in spite of this universal familiarity, few realise that operations for rupture, though among the most ancient of operations, still usually produce results far from the ideal of a complete and permanent cure. Though most of this tale is stale, the subject merits repeated review, because operations for hernia are among those most commonly performed.

Surveys and pronouncements of results are chiefly of value where long-term results are assessed. MacLeod (1955) has shown the fallacy of relying, in adults, on simple herniotomy and repair of the fascia transversalis at the internal ring. He claims that his own results with these simple methods were so poor that he has published them as a warning to others—a most magnanimous gesture. The results of different repairs done by various surgeons are shown in table I and speak for themselves. One notable point is the scarcity of reviews made more than 2 years after operation. Douglas (1953), with a report on tantalum mesh at 5 years, and Shouldice (1953), with a review of recurrent herniæ at 4 years, are the only ones to give clearly defined long-term figures.

Another point appearing from table I is that the use of the patient's own tissues for repair did not appear to give so high a percentage of permanent results as when either silk or metal was incorporated in the repair. The concrete of fibrosis does not seem to be so good at withstanding strains as does the reinforced concrete of a permanent mesh embedded in fibrous tissue.

Gupta (1954) boldly proclaims that the figures for recurrent inguinal hernia are 15–30%, and table I confirms that some salvos fall within that range, though others appear to be distinctly nearer the target of no recurrence.

Hagan and Rhoads (1953), to find out how long after the initial operation recurrences may be expected, analysed the histories of 75 patients presenting with recurrent herniæ. They found that 55% of recurrences had occurred in 2 years, 75% in 5 years, and 85% in 10 years, and they depressingly noted that recurrences may appear as late as 40 years after operation. One is tempted to believe that a further survey might break this record by revealing a recurrence after half a century. Since at 40 or 50 years both the surgeon and the patient may defy record-breaking attempts by dying, I am among those neither ambitious nor patient enough for that attempt and am prepared to settle for the simple solution of finding the true recurrence-rate by multiplying a 5-year result by 4·3.

Moloney et al (1948) advocated the use of a darn of monofilamentous nylon for the repair of herniæ, agreement being expressed with the views of other workers who said that five years should elapse before it is worth while reviewing the recurrence-rate. Accordingly I now review 253 nylon-darn repairs for inguinal herniæ (222 in males in whom 22 were recurrent, and 31 in females) all done by me more than 5 years previously.

Moloney et al (1948) claimed that monofilamentous nylon stood up to the misfortune of sepsis better than did anything previously used, and was therefore particularly valuable for strangulated herniæ because of the potential infection of these wounds. This view has been substantiated by this present study, which includes a survey of the effect of nylon sutures on the healing of 2181 repairs of different varieties of hernia done by the general surgeons and their assistants at the Radcliffe Infirmary and the Churchill Hospital in the 9 years of 1946–54.

TABLE I—RESULTS OF REPAIR OF INGUINAL AND FEMORAL HERNIÆ BY VARIOUS SURGEONS

Reference	No	Type of hernia	Type of repair	% traced	Length of follow-up after last operation	Recurrence-rate (%)	Remarks
MacLeod (1955)	255	Primary inguinal	Various	90	2 yr	12·8	Males aged more than 17
	34	Recurrent inguinal	Various	90	2 yr	36·7	
	161	Primary inguinal	Simple herniotomy	83	2 yr	14·3	
	92	Inguinal	Posterior silk-lattice repair	92	2 yr	8·2	
Mair (1946)	113	Inguinal	Whole skin	76	1 yr	1	
citing 4 authors	320	Indirect inguinal	McArthur fascial	?	1–3 yr	3·0–9·3

citing 9 authors	More than 1000	Direct inguinal	Bassini	?	?	5–30	Including Page (1943) operations on London Police 25·8%
Rose (1953)	50	Inguinal	Full thickness skin-graft	?	2 yr	6	
Palumbo and Mighell (1954)	867	Primary indirect inguinal	Cotton or silk Halsted-Bassini	87·7	1 yr	1	
Hagan and Rhoads (1953	74	Primary femoral	? Imbrication in layers of various suture materials	71	2 yr	2·9	
	219	Primary direct inguinal		?	2 yr	5·1	Mortality 0·29%
	714	Primary indirect inguinal		?	2 yr	4·1	
	75	Recurrent inguinal		?	2 yr	21	
Koontz (1951)	[illegible]	Inguinal	Tantalum mesh		1–30 mos	1·3	Herniæ with large defects and poor tissues
Douglas (1953)	32	Various large recurrent	Tantalum mesh	100	5 yr	6·3	Recurrences both inguinal
Abel and Hunt (1948)	300	Various	Steel-wire darn	No follow-up	0–? yr	See text	General report on 10 years experience of wire in abdominal wall
Shouldice (1953)	8317	Inguinal and femoral mostly	Silk or steel wire	60	10 mos – 10 yr	1·03	
	111	Recurrent inguinal or femoral	Steel wire (? some silk)	58·5	4 yr	3·1	
Ryan (1953)	150	Recurrent inguinal and femoral	Steel wire (? some silk)	100	2 yr	1·3	

TABLE II—ANALYSIS OF WOUND DISTURBANCES AFTER HERNIÆ
(2181 repairs in 1973 patients [235 with strangulation, 1738 without strangulation])

Type of hernia	No	Stitch and superficial sepsis	Hæmatoma without discharge	Deep sepsis (immediate and delayed) or discharging hæmatoma	Resulting sinuses needing removal of nylon	Nature of sutures		Resulting sinuses not needing removal of nylon	Nature of sutures	
						Braided	Monofilamentous		Braided	Monofilamentous
Inguinal										
Strnagulated	118	0	0	5	3	3	0	2	0	2
Non-strangulated	1671	15	15	19	11	7	4	8	3	5
Femoral										
Strangulated	88	1	0	3	0	0	0	3	0	3
Non-strangulated	108	0	2	2	2	2	0	0	0	0
Incisional										
Strangulated	13	0	See text	0	0	0	0	0	0	0
Non-strangulated	80	0	"	7	3	3	0	4	1	3
Umbilical										
Strangulated	16	0	See text	2	1	1	0	1	0	1
Non-strangulated	87	0	"	2	0	0	0	2	1	1
Total	2181	16 (*0 7%*)	17 (*0 7%*)	40 (*1 9%*)	20 (*0 9%*)	16 (*0 6%*)	4 (*0 4%*)	20 (*1%*)	*5*	15

Of 21 sinuses containing braided nylon 16 needed removal of sutures (in 1000 repairs)
Of 19 sinuses containing monofilamentous nylon 4 needed removal of sutures (in 1000 repairs)

Both varieties of nylon, braided and monofilamentous, were used in these two hospitals, and various surgeons, myself included, used both varieties at different times The number of times that each variety was used was estimated by a survey of the operation notes (which do not always state this detail) and in other ways For the general assessment of results it can be assumed that, of about *2000* nylon darns, about *1000* were repaired with braided nylon and 1000 with monofilamentous nylon

Analysis of Wound Disturbances in 2181 Repairs

Strangulated and non-strangulated herniæ are separately analysed (table II), but the results for both and for the various varieties of abdominal herniæ are totalled

Stitch and Superficial Sepsis, and Hæmatoma, without Discharge

Stitch and superficial sepsis occurred in 0 7% and hæmatoma without a discharge from the wound also in 0 7%

Because of the large size of many incisional and umbilical herniæ there often remains in the superficial fat, after the aponeurosis has been repaired, a large cavity which is at times difficult to obliterate completely Therefore the incidence of hæmatoma after these repairs is higher than that following repairs in the inguinal and femoral regions, where the closure is easier The exact incidence after the repair of large ventral herniæ was very difficult to ascertain from the postoperative notes, which did not state clearly whether or not a hæmatoma had formed and what was primarily a hæmatoma and what sepsis In consequence there was no attempt with ventral herniæ to separate the categories of hæmatoma, immediate sepsis, and delayed sepsis, but hæmatomata following inguinal and femoral repairs were analysed and are shown in table III The only conclusion, from such small figures, is that, in a wound showing a large hæmatoma, healing can sometimes take place without the need for removal of nylon sutures, but sometimes removal may be necessary to promote healing

Deep Sepsis (Immediate and Delayed) and Discharging Hæmatoma

This occurred in *1 9%* of *2181* repairs (table IV)

Immediate deep sepsis was considered as sepsis developing within two weeks of operation, and, for reasons already given, deep sepsis was assessed for inguinal and femoral herniæ only In *1985* inguinal and femoral repairs (strangulated and non-strangulated) immediate deep sepsis developed in 13 cases (0 7%) Out of all the many instances of potential infection, especially with strangulated herniæ, and the 13 instances of freely discharging wounds it was necessary to remove nylon from

TABLE III—ANALYSIS OF WOUNDS SHOWING HÆMATOMA
(Inguinal and femoral herniæ only)

Type of hernia	No	With unbroken wound	With temporary sinus healing	Type of suture		Sinus needing removal of nylon	Type of suture

Total	1985	13 (*0 7%*)	2 (*0 1%*)	1	1	11 (*0 6%*)	3	8	11 (*0 6%*)	11 (*0 6%*)	10	1	0

B braided *M*, monofilamentous

the wound to heal sinus formation in only 2 instances (1 monofilamentous and 1 braided). This is clear enough evidence that herniæ repaired with nylon stand up well to the misfortunes of both potential infection and immediate frank sepsis, and generally heal without the need for removal of the nylon.

Delayed deep sepsis is a different matter. It was analysed in detail only for inguinal and femoral herniæ (strangulated and non-strangulated), and a striking result was found. Monofilamentous nylon is seen to be almost completely innocent as a trouble-maker, whereas braided nylon compares very badly, being found to be no better than silk and thread in its inability to stay in the tissues in a high proportion of instances. Delayed sepsis developed in 11 cases (0·6%), of which 10 were with braided nylon, and the only time that it developed with monofilamentous nylon a layer of thread had also been used in the repair.

TABLE V—COMPARISON OF HEALING OF INFECTED WOUNDS SUTURED WITH NYLON OR WITH CATGUT AFTER APPENDICECTOMY

—		Severity			
		1	2	3	4*
Catgut	Number of cases	336	208	83	64
	Percentage with wound sepsis	8	28	37	50
	Percentage with late discharge of suture	2	5	8	9
Nylon	Number of cases	119	70	49	35
	Percentage with wound sepsis	3	6	10	10
	Percentage with late discharge of suture	1	3	2	5

(Modified from a table in *British Journal of Surgery*.)
* General peritonitis

This delayed reaction appears to be due either to sepsis or to a foreign-body reaction, and it has been noted before, especially by Edwards (1943) in his review of recurrent hernia in soldiers, when he called attention to the reaction with silk and in consequence made a plea for abandoning the use of floss silk as a material for repair. In this reaction the wound appears to heal well, and then, at a variable interval after operation, a swelling develops which eventually discharges on to the surface. The times of onset of this development in those instances after inguinal repairs were 1, 3, 3, 5, 18, and 18 months after non-strangulated cases and 2, 3, and 3 months after strangulated cases. This series under analysis was completed in 1954, and there was no trace of this delayed reaction developing later than 18 months after operation.

Nylon has been given a bad name for sinuses in some quarters, and this appears to be justified for braided nylon. This tendency for a high rate of sinus formation after the use of braided nylon has been noted in the closure of abdominal wounds, and for this reason, after trying it for a time, I completely abandoned its use in favour of monofilamentous nylon.

TABLE VI—BOWEL RESECTIONS AND DEATHS

Type of hernia	Bowel resections (strangulation only)	Deaths (all causes)
Inguinal

Total	28 (*12%*)	17 (15 strangulated) S 6·3% Non S 0·01%

TABLE VII—PERSONAL SERIES OF INGUINAL REPAIRS
(219 patients repaired more than 5 years, 76% contacted)

Total sides	Superficial sepsis	Deep sepsis		Discharging hæmatoma	Recurrence	Died
		Immediate	Delayed			
253	1	1 monofilamentous (sutures removed)	1 braided (sutures removed)	1 monofilamentous (sutures removed) 2 scrotal (monofilamentous) incised and healed	2 (1 braided after enormous recurrent defect 1 monofilamentous after hæmatoma)	1 (acute retention, prostatectomy)

Monofilamentous nylon appears to be a reliable suture. In this series, when it was used in 1000 repairs of all variety of herniæ, sutures had to be removed on only four occasions to heal sinuses. Should the removal of monofilamentous nylon be necessary, this is a simple matter owing to the ease with which it slides through the tissues compared with the great difficulty of excising a braided suture, which does not readily move along its track when pulled on. There was one recurrence associated with the removal of the sutures, an instance of hæmatoma following one of my own operations and leading to sinus formation in a wound which would not settle until the sutures were removed.

Over 100 strangulated inguinal and femoral herniæ were repaired with an immediate darn of monofilamentous nylon with no instance of nylon removal. Table II shows that monofilamentous nylon stood up well to sepsis after strangulation. Braided nylon produced 3% of sinuses in the strangulated inguinal repairs.

TABLE VIII—RETURNED RECURRENCES
(In 2181 repairs in 1973 patients by general surgical staff)

Type of hernia	No	Recurrences	After wound sepsis	After hæmatoma	After primary healing
Inguinal					
Strangulated	118	3 (*3·0%*)	0	1	2
Non-strangulated	1671	6 (*0·4%*)	0	1	5
Femoral					
Strangulated	88	1 (*1·0%*)	1	0	0
Non-strangulated	108	0	0	0	0
Incisional					
Strangulated	13	0	0	0	0
Non strangulated	80	7 (*9·0%*)	4	0	3
Umbilical					
Strangulated	16	2 (*13·0%*)	2	0	0
Non-strangulated	87	1 (*1·0%*)	1	0	0
Total	2181	20 (*1·0%*)	8	2	10

There is no justification for the method of "repairing" strangulated cases with catgut initially and repairing the recurrences by sounder means, because wound troubles are more likely if catgut is used. This was shown in an analysis made by Moloney et al. (1950) of the comparative sepsis-rate in wounds contaminated with septic material in operations for acute appendicitis and sutured either with nylon or with catgut and shown in table V. The table apparently shows that infected wounds sutured with nylon heal better and discharge the sutures less frequently than do those sutured with catgut. Every substance used for suture can cause a sinus, steel and tantalum included, but other comparative figures are not available to match those for monofilamentous nylon, which in this series of herniæ was responsible for 0·4% of sinuses.

Comments on Patients with Strangulated Herniæ and on Deaths

The number (12%) of necessary resections of bowel in strangulated herniæ (table VI) shows that delay is as dangerous as ever, and the absence of bowel resections in the elective group confirms again that the best time to treat a hernia is before it strangulates The low incidence (6·3%) of deaths in the strangulated group is an index of satisfactory treatment but still re-emphasises the great danger of strangulation In the elective group there were 2 deaths, one pointing to the constant need for care in assessing the urinary system before attempting the repair of hernia in the elderly patient, and the other emphasising the danger inherent in the treatment of a large incisional hernia, this patient developing intestinal obstruction after the operation

Recurrence Rate

5-Year Follow-up of Personal Series of Inguinal Herniæ

For the purpose of studying the incidence of recurrence I made a study of my own patients operated on in 1946–51 (table VII), all patients being operated on more than 5 years previously All types of herniæ were studied, but only the numbers for inguinal herniæ were large enough to be profitable for conclusions

As is usual in such searches, it was found that several patients had emigrated overseas and others had died from causes unconnected with their hernia Still other patients could not be traced

At the end of the search about 76% of 219 patients who had submitted to about 253 inguinal repairs were found and replied to the questions All the patients had been seen at the hospital outpatient clinic 6 months after the operation, and from this source and from their replies there was nothing to suggest that any testicular atrophy or hydrocele had resulted from the operation The only recurrent herniæ which were traced by this survey and from a study of the patient's notes after further visits to the hospital for follow-up for herniæ or other causes were 2 patients who were returned because of further trouble

(1) A man, aged 51, had both a direct inguinal hernia and a femoral hernia on the one side, and the repair did not settle well after the operation, the wound having the appearance of a deep hæmatoma The hardness was replaced by a mass which did not settle, and after a year a recurrence was evident A bunched-up mass of monofilamentous nylon was excised at the site of the old hæmatoma, and a direct weakness was repaired with a further darn of monofilamentous nylon, and there has been no further trouble in the past 4 years

(2) A man, aged 83, had been operated on previously by one of my assistants for a massive inguinal hernia which had strangulated Because of the poor state of the patient the repair was not thorough, and the hernia had recurred within 3 months The defect was huge, the contents of the sac being half the contents of the abdominal cavity, and the tissues were poor, the problems being more those of a large incisional hernia than of the usual inguinal hernia Because of the recurring attacks of pain I decided to try to repair the defect, again braided nylon being used All the ligamentous tissue below had shorn away, and the only remaining soft tissue below was muscle and fascia, into which I darned the nylon Within 5 months the patient had returned again with a huge defect While we were wondering how to stem the bulge, the patient freed us of further anxiety on his account by rupturing his aorta

These two cases are the only traceable recurrences (0·8%) from the 253 inguinal repairs after 5 years

" Return " Recurrences in General

In the total series of 2181 repairs done in the 9 years from 1946–54 by the general surgeons and their staff in the United Oxford Hospitals—the recurrence-rate was studied by a search of follow-up notes and subsequent admissions because with such large numbers, an approach to each patient was impracticable This incomplete assessment of the recurrence-rate was therefore made only on " returned " recurrences, but the figures are included for what they are worth (table VIII) They do at least suggest that the low rate of " returns " after nylon-darn repairs in strangulated cases is a strong pointer to its potential usefulness in strangulation Since patients are usually fairly sympathetic towards a surgeon who has initially saved their lives, if those patients develop recurrences they are less likely to go outside their own district for subsequent treatment, and, since the two hospitals concerned in this survey are the only ones serving the area, " return " and true recurrence-rates are therefore likely to coincide closely in this instance

Inguinal Repairs

Of 1789 inguinal repairs 6 recurrences returned to us, including the 2 of my own Of the 4 others, 2 were after repairs by one of my house-surgeons, and, when I reoperated on both herniæ, it was quite clear from the sites of the recurrence that the darns had been incompletely done at the medial ends of the inguinal canal—a common cause of recurrence The same remarks apply to the other 2 instances of recurrence, which were not under my care

Strangulated Inguinal Herniæ

There were 3 recurrences in 118 repairs, 1 being the recurrence already mentioned of the large hernia in the patient who finally ruptured his aorta The 2nd recurrence followed a repair by a house-surgeon who had clearly not darned the canal adequately The 3rd was that which followed a bloc-excision of a mass of tissue in the inguinal canal for removal of braided nylon and an accompanying sinus

Femoral Herniæ

From 108 repairs of non-strangulated femoral herniæ there were no " return " cases, and from 88 repairs of strangulated herniæ there was only 1 " return " recurrence, which was consequent on sepsis

Incisional Herniæ

There was no " return " case after 13 repairs of strangulated herniæ, but in 80 non-strangulated cases there were 7% " return " recurrences, in which the usual factors of sepsis, hæmatoma, obesity, and distension played a part It was not always clear in what manner the nylon was used in these repairs

Umbilical Herniæ (Adults Only)

There were 13% " returns " in 16 patients after strangulation and 1% in 8 patients after non-strangulation Perhaps the stretching of the years will show more returns

Discussion

MacLeod (1955) has clearly shown that excision of the sac either alone or with the addition of repair of the fascia transversalis is insufficient to give a lasting repair Most operators who have analysed their results, or studied those of others, are convinced that some form of repair is necessary

The Bassini and the overlapping repairs with catgut which hope to unit the muscle to aponeuroses often succeed because the sac has been excised and the muscles of the canal are fairly satisfactory But in too many the repair lasts only as long as the initial fibrosis induced by the catgut, and, when Nature removes in time most of the fibrosis, the thin remaining area of fibrous tissue and the muscles, which were stretched to allow approximation, give way

Tanner (1942) says that an aid to any such repair is the relaxing of the muscle by an incision in the rectus sheath When such repairs, either alone or with relaxing incisions, are accompanied by wide-biting and loosely applied unabsorbable sutures they become virtually a darn of interrupted stitches, and what virtue has been largely attributed to the relaxing incision may really be due to the presence of the unabsorbable sutures

The inclusion of some additional substance, be it heterogeneous or homogeneous, seems to aid a repair Most substances have been used to stem insistent bulging of the peritoneal cavity fabric materials, including silk, cotton, and linen, metals, including silver, gold, steel, and tantalum, and plastics, including nylon, polyethylene, and 'Terylene' The homogeneous tissues of skin, fascia, peritoneal sac, and even bone have been included in the repairs, but the repair should be possible without resort to bone-grafts or, as recently reported, diced costal-cartilage graft

Douglas (1949) has shown that silk, cotton, and linen are all mostly absorbed by the tissues and lose their tensile strength to a great extent or completely after a stay in the tissues of 6 months Of the metals, gold adds to the expense but, if properly tested, might prove just the thing for those who can afford it, and silver effects a good repair, as Cole (1941) has shown, though it irritates the tissues and does not always stand up well to sepsis Tantalum as a braided metal is difficult to use and becomes fragmented, as Ascroft (1952) has shown Stainless steel is undoubtedly the best and least irritating of the metals, and has been advocated by Abel and Hunt (1948) It may cause a sinus when used in abdominal-wall incisions and may give trouble occasionally from broken ends Mr Abel, who has used it in the repair of abdominal wounds and herniæ for 10 years, tells me he has occasionally had "broken-end" trouble in the repair of ventral incisions but has not had a sinus or "broken-end" trouble in the repair of an inguinal hernia In his careful and capable hands the darn with steel has shown only 1 "return" case. Shouldice (1953) and Ryan (1953) have latterly used steel but have not yet produced a long-term study of cases in which steel alone has been used

All available homogeneous tissues have been used Skin gives occasional dermoid-cystic troubles, is tedious to handle, and is not especially notable in producing a low recurrence-rate Most surgeons have stopped damaging the thigh to secure fascia to repair the abdominal wall The McArthur operation will provide, some have argued, enough fascia for a repair in those patients in whom no repair is necessary, and, for the repair of large herniæ in the inguinal region and for ventral and femoral herniæ, the external oblique fascia does not provide a sufficiency of strips Some doubt the permanency of fascia, and a study of the results with fascia has not shown an outstandingly low recurrence-rate

My general impression about the repair of herniæ is much the same as is the engineer's about the problem of containing stresses—that the concrete of fibrosis is more liable to fracture and give way under stress than is a reinforced concrete of fibrosis plus an included permanent framework

So long as the sutures of a darn are laid loosely they will act as a reinforcement in this way The tissues stand up well to short-acting intermittent stresses and pressures, as the soles of the feet illustrate, and the untaut sutures of a darn will not cut out of their fibrous tunnels so long as the strains are not continuous, which is not more likely to happen to the inguinal region than to the palms and soles

After comparing these present results with others published I believe that the non-porous, pliant, and permanent plastic is better than the porous and impermanent silk, and is equal to, and may be better than, the more tedious, rigid, and fragmenting steel

The persistent sinus calling for suture-removal needs comment. It may occur with any substance introduced into the tissues, even with the patient's own tissues after sepsis But a persistent sinus must be regarded as only one complication after a hernia operation and as something less than the complete failure of recurrence In the case of a repair with monofilamentous nylon it is a complication easily put right, sometimes in the outpatient department with a hook or forceps Since granulation and healing can go on around nylon sutures, any sinus should not be disturbed for at least 2 months

Of the 4 instances of persistent sinuses from which it was necessary to remove monofilamentous nylon the cause in 2 was that the layer used to suture the external oblique had worked free owing to sepsis and lay in an abscess cavity, the underlying darns being intact, wherefore they were not disturbed, in the 3rd instance a hæmatoma of the wound had caused the whole darn to become loose and lie in an abscess cavity (a case described earlier), and in the 4th instance thread as well as nylon had been used in the darn, and which suture was chiefly responsible was not clear, because the whole of the disturbed tissue was excised in one block These sources of trouble were countered as follows since the external oblique aponeurosis does not add any strength to a repair except in an overlapping procedure, shown by the way in which interstitial herniæ bulge freely beneath an intact external oblique, I now suture this layer with catgut which, if it causes a sinus, usually comes away sooner than does nylon, a large hæmatoma, which can destroy any repair, calls for no further comment, and it is probably preferable to darn with one material at a time

In my total experience over 12 years with monofilamentous nylon in the repair of herniæ, in public and in private patients, I have found it necessary to remove the whole darn, in addition to the case of hæmatoma cited above, once for an inguinal hernia and once for a femoral hernia Neither of the latter recurred.

If the recurrence-rate in my own series of inguinal repairs by a nylon darn (0 8%) is added to the rate of sinuses after monofilamentous repairs for the general series (0 4%), the total failure-rate is 1 2%, which is as good, if not better, for a 5-year figure as any result by any other material or method that I can trace

Brief Technical Details

Shaving of the hair but no other preparation until the time of operation. Iodine skin antiseptic, removed by spirit to stop a rash Skin-crease incision, one medially placed crease incision for bilateral repairs After sac excision the cremaster muscle is not sutured Plication only of the bulge in the lesser direct herniæ. Repair of the fascia transversalis at the neck of the cord in direct and indirect herniæ and at the orifice of a direct hernia

The darn is made with no 7 in two layers, either in parallel lines or in stay-lacing fashion or any pattern desired, so long as no large gaps remain. Details are given by Moloney et al (1948), who set out the requirements for any darn or lattice.

The external oblique, for reasons given earlier, and because it plays no part in the strength of the repair, and because nylon in the external oblique aponeurosis is readily palpable in the tissues though not in the darn beneath the external oblique, is closed with catgut The fat is closed with fine nylon or with fine catgut, and the skin by your own favoured method, my own being clips

Femoral herniæ are repaired from below where possible by a J-shaped needle carrying no 7 nylon, 3 or 4 sutures being inserted through Cooper's and Poupart's ligaments The medial sutures are tied firmly, but the lateral ones are tied loosely because the femoral vein must not be occluded When the darning is done from above, the inguinal canal is also darned

Ventral herniæ are repaired by cutting away all the fibrous tissues of the sac until one reaches the sound edges of the aponeurosis These are approximated in the usual way with over-and-over stitches, and a darn is laid on top of the first layer, the sutures being carried out wide of the main suture line

My usual practice after operation is to get the patient up on the same day if the operation is done early that day, otherwise the next day The patient may go home from the 3rd day onwards, depending on personal needs, but the usual time for discharge is 5–7 days, the " hospice " aspect of " hospital " not being entirely overlooked I do not order routine physiotherapy, using it mostly where special needs dictate, though many of my patients are included in the mass ward-drill for postoperative patients

The patient may do light work as soon as he feels like it, usually 2 weeks after operation, and 1 month after operation he may do any work or join a weight-lifting club

Summary

A personal series of 253 inguinal herniæ repaired with a nylon darn and surveyed more than 5 years after the last operation, with a 76% follow-up, revealed 2 recurrences (0 8%)

A series of 2181 abdominal herniæ repaired with nylon sutures by the general surgeons and their staff in the Radcliffe Infirmary and Churchill Hospital in Oxford have been reviewed from the aspects of sepsis (immediate and delayed), sinuses, hæmatomata, and " returns " with recurrence

Both monofilamentous and braided nylon were used, each in about 1000 instances, with no apparent difference in the soundness of the resulting repairs

Both varieties of nylon reacted well to immediate sepsis and needed removal for that reason in only 1 in 1000 repairs, for each variety

Both varieties showed about the same number of sinuses after sepsis and hæmatomata (21 braided, 19 monofilamentous), but the subsequent healing differed considerably With braided nylon the 21 sinuses required removal of the nylon in 17 instances, whereas with the monofilamentous nylon 19 sinuses required removal of sutures in only 4 instances

The cause of many of the sinuses and of the need for removal of the nylon was a delayed reaction seen almost entirely with the braided variety (in inguinal and femoral herniæ only, 10 braided to 1 (?) monofilamentous), which comes on 1–18 months after the insertion of the sutures and may be more of a foreign-body reaction than sepsis

" Return " recurrences for the different varieties of abdominal herniæ are analysed

A darn of monofilamentous nylon is easy to insert at operation, reacts well to primary sepsis, has a negligible " delayed " reaction, provides a sounder and more permanent repair than most, being bettered by none, and is recommended as a good method for all varieties of herniæ whether strangulated, non-strangulated, or recurrent

I am grateful to my general surgical colleagues, Mr D A Abernethy, Mr D C Corry, Mr A E Elliot Smith, and Mr A S Till, for allowing me to study the notes of patients who were under their care, and to the registrars and house-surgeons who did many of the 2000 repairs This study would not have been possibl without the secretarial help granted by Prof T P Kilner and paid for by the University of Oxford, and to Mrs J Piper, who gave thi invaluable secretarial aid, I am especially grateful

From the Departments of Medicine, Pharmacology and Therapeutics, University of St Andrews, Queen's College, Dundee

The hypoglycæmic action of the sulphonylureas is well established and much experience has been gained in their clinical application, but, so long as there is doubt about their mechanism of action, there will be hesitation in recommending their widespread or uncontrolled use

In the study of the action of any hypoglycæmic agent it is important to know (1) the effective range of blood levels, (2) how long an adequate level is maintained, and (3) the proportion of the body volume in which the drug is distributed

Pharmacological Studies

The blood-level of carbutamide stated to be effective is 6–8 mg per 100 ml (Quattrin et al 1956) and of tolbutamide 8–18 mg per 100 ml (Baird and Duncan

TABLE I—RATES OF FALL OF LEVELS OF CARBUTAMIDE IN BLOOD AND OF TOLBUTAMIDE IN PLASMA IN NORMAL SUBJECTS AND DIABETICS

Hours after 3 g of drug by mouth	Blood carbutamide (8 subjects) (Mg per 100 ml)	Plasma tolbutamide (6 subjects) (Mg per 100 ml)
4	14 5* (12 0–16 5)†	30 5 (20 9–33 4)
12	—	5 2 (2 2–11·0)
24	10·4 (8 8–11 6)	1·4 (0 7–3 6)
48	6 9 (5 8–9 4)	0 2 (0 0–0 9)
72	4 8 (6 6–3 6)	Nil
96	3 1 (2·0–4 7)	
Mean half life (hr)	40 0	3 5

* Mean † Range

1957) Our clinical data are in agreement with these statements The times for which adequate levels of these two sulphonylureas are maintained are shown in table I It is apparent that within 12 hours the level of tolbutamide has already passed its peak and becomes barely effective, whereas an effective level of carbutamide persists more than four times as long If such data are plotted on a semi-log scale for individual patients, the biological half-life of each drug can be estimated (fig 1) In this example the half-life of tolbutamide was about 4 hours and that of carbutamide about 33 hours

By extrapolating the straight lines shown in fig 1 to zero time the theoretical initial levels of these drugs can be derived Since the dose of each drug was 3 g, it was calculated that carbutamide and tolbutamide were diluted in 23 8 and 13 1 litres respectively at zero time This corresponds to 32% and 17 5% of the bodyweight These calculations were made on the assumption that the drugs were completely absorbed the amounts excreted during the process of absorption have been disregarded A similar volume of distribution was calculated when sodium carbutamide 0 5 g was administered intravenously to an anuric patient

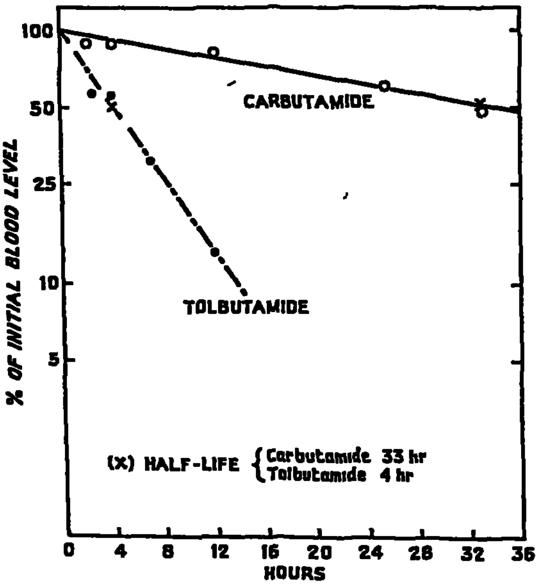

Fig 1—Rate of disposal of carbutamide and of tolbutamide from the blood

The theoretical initial level of each drug in the blood was obtained by extrapolation of the line representing the rate of decrease of the blood levels on a log scale Here the blood levels are recorded on a log percentage scale, so that the half-life can be readily assessed

Similar studies of blood-tolbutamide levels in twelve other patients showed that tolbutamide could be regarded as being distributed in a volume representing 15–25% of the bodyweight, which corresponds well to the volume of the extracellular fluid These results are in good agreement with those of Wick et al (1956) using radioactive-labelled tolbutamide in nephrectomised eviscerated rabbits and with those obtained by Quattrin et al (1956) for carbutamide

The restriction of tolbutamide to the extracellular compartment in man has been confirmed in this study by separate measurements of its levels in whole blood and plasma (table II) These results did not exclude the possibility that the drugs were preferentially concentrated in certain body tissues, such as the liver Accordingly the levels of these sulphonylureas (tolbutamide and carbutamide) in the liver and the plasma of rats were compared (table II)

TABLE II—RATIO OF TISSUE TO PLASMA LEVELS OF SULPHONYLUREAS

Sulphonylurea	Ratio $\frac{\text{Level in tissues or C.S.F. (mg. per 100 g.)}}{\text{Level in plasma (mg. per 100 ml.)}}$				
	Human erythrocytes		Rat liver		Cerebrospinal fluid
	In vivo	In vitro	In vivo	In vitro	
Tolbutamide	0 08	0 02	0 32	0 23	0 00
Carbutamide	0 02	0 02	0 27	0 12	

If the sulphonylurea had been concentrated within the liver, the ratio of the level in this tissue to that in plasma would have been greater than 1 In fact the ratios were considerably less than 1 Incubation of surviving cells (rat liver, human erythrocytes) with the drugs in vitro yielded similar results (table II)

Although tolbutamide appeared to be distributed in the extracellular fluid, the results of a single trial indicated the existence of a blood-brain barrier In this study no tolbutamide was detected in normal cerebrospinal fluid 2 hours after the administration of 2 g by mouth, when the level in the plasma was 24 mg per 100 ml

Estimations of Plasma-tolbutamide

When plasma levels of the sulphonylureas are measured, it cannot be assumed that only the therapeutically active form is being estimated In fact Quattrin et al (1956) found that up to 20% of carbutamide in human blood was in the inactive acetylated form, and, using the method described below, we have shown that 24 hours after a single oral dose of the active drug 10–28% of tolbutamide occurs in plasma as the inactive carboxylic ester

Measurement of Ratio of Carboxytolbutamide to Tolbutamide

A sample of carboxytolbutamide was prepared from several 24-hour collections of urine passed by patients receiving large doses of tolbutamide This compound was precipitated by acidifying the urine to pH 1 and allowing it to stand for 12 hours The white crystalline precipitate was filtered off and then purified by redissolving in ethanol, concentrating at room temperature, and then precipitating by seeding This was repeated twice The melting-point of the product was 215°C, which is that of carboxytolbutamide (Louis et al 1956)

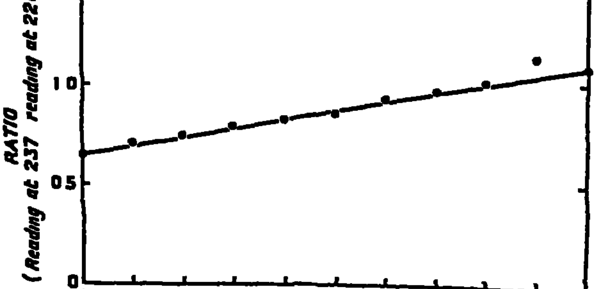

Fig 2—Proportions of tolbutamide and carboxytolbutamide in mixtures of these compounds

Ratio of readings on ultraviolet spectrophotometer at 237 mμ to those at 228 mμ are given on the ordinate, and the corresponding proportions of tolbutamide and carboxytolbutamide on the abscissæ

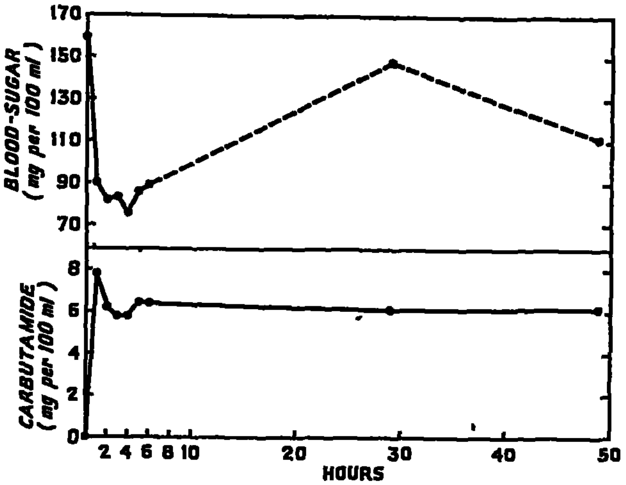

Fig 3—Levels of carbutamide and sugar in the blood of the anuric patient given sodium carbutamide 0 5 g intravenously at time 0

The maximum absorption of tolbutamide in alcohol took place at 228 mμ (measured with a 'Unicam SP 500' spectrophotometer), and that of carboxytolbutamide in alcohol at 237 mμ Equal weights of tolbutamide and of carboxytolbutamide were dissolved in identical volumes of ethanol Mixtures of these two solutions were then made in nine different proportions The spectrophotometric absorption of the mixtures and of the two pure solutions was then read at 228 and 237 mμ, and the ratio $\frac{\text{absorption at 237}}{\text{absorption at 228}}$ was then calculated for each of them

When this ratio was plotted against the proportional levels of carboxytolbutamide and of tolbutamide, a straight line was obtained (fig 2) In the case of tolbutamide alone the ratio was 0 656 and in the case of carboxytolbutamide alone it was 1 08 Intermediate ratios correspond to proportions of these two compounds which can be read off the figure In this way the proportion of carboxytolbutamide in blood and urine specimens was determined

Excretion of Tolbutamide

The plasma level of sulphonylurea depends not only on the rate of its metabolic change in the body but also on its excretion The route of excretion is probably entirely renal

This was illustrated by some observations on an anuric patient, in whom the blood level of carbutamide remained practically constant during the 50-hour observation period following intravenous injection of sodium carbutamide 0 5 g (fig 3) It proved impracticable to calculate the renal clearance of tolbutamide because of the variable blank values obtained in separate specimens of urine, the high proportion of the carboxy derivative in the urine, and an unknown proportion of tolbutamide bound to plasma-proteins Nevertheless an indirect assessment of the kidney's action on tolbutamide was obtained by following the rate of its disappearance from the plasma under a variety of circumstances affecting the kidney (table III)

In two non-diabetic patients with considerable impairment of glomerular filtration, estimated by the clearance of endogenous creatinine, there was only a small reduction in the rate of disappearance of tolbutamide from the plasma compared with the mean rate in six normal subjects On the other hand, probenecid ('Benemid'), which affects tubular transport mechanisms, slowed the rate of disappearance considerably Sodium bicarbonate 20 g did not appreciably accelerate the rate of disappearance of tolbutamide from the plasma in a single normal subject

We conclude that renal tubular transport is important in the excretion of tolbutamide, as might indeed be inferred from the fact that the proportion of tolbutamide to carboxytolbutamide is several times greater in the plasma than it is in the urine

Mode of Action

On reviewing the published work of others, there remain two plausible explanations of the mode of action of the hypoglycæmic sulphonylureas

(1) The first is that they stimulate the release of insulin from the pancreas This hypothesis accords with the fact that in pancreatectomised patients the sulphonylureas do not have a hypoglycæmic effect In fact the type of diabetic that responds best is precisely the type that does not lack insulin—as shown by plasma-insulin assays and extraction of insulin from the pancreas post mortem (Wrenshall and Best 1956) The work of Ashworth and Haist (1956), on beta-cell hyperplasia induced by the sulphonylureas, and of Loubatières (1955) and Colwell et al (1957), showing the increased efficacy of these compounds when infused into the pancreaticoduodenal artery of dogs, support this explanation Pozza et al (1956) demonstrated an increase of hypoglycæmic activity in blood containing tolbutamide perfused through the pancreas of dogs

A hypothesis with similar implications is that the main action of the hypoglycæmic agent is the inhibition of insulinase (Mirsky et al 1956), but more recent work has indicated that the blood-tolbutamide concentrations obtained in clinical practice have no anti-insulinase action (Vaughan 1956), and no effect has been noted on the rate of destruction of insulin labelled with ^{131}I (Wick et al 1957, Volk et al 1957)

(2) The second main explanation is that hypoglycæmia results from a decreased glucose output from the liver Much work supports this theory, including studies in man of the reduced conversion of fructose and galactose to glucose (Renold et al 1956), which normally takes place in the liver and direct measurements of the hepatic output of glucose by catheterisation of the hepatic vein in dogs (Anderson et al 1956, Purnell et al 1956) and man (Recant and Fischer 1957a)

The explanation offered at one time by German workers that tolbutamide inhibits the production of glucagon by the alpha-cells of the islets of Langerhans is now no longer supported by the Germans themselves (von Holt et al 1956, Ferner and Runge 1956), and it certainly does not account for the refractoriness of alloxan diabetes to the hypoglycæmic action of the sulphonylureas Most workers agree that glucagon and adrenaline still produce their typical hyperglycæmic action in the presence of these hypoglycæmic agents (Franke and Fuchs 1955)

Other hypotheses, such as those involving actions on the pituitary, adrenal, or thyroid glands (Mortimore et al 1956) or on absorption of food from the intestine (Friedlich et al 1956), or on the renal threshold for

TABLE III—RATE OF DISAPPEARANCE OF TOLBUTAMIDE FROM PLASMA IN VARIOUS CIRCUMSTANCES

	Plasma-tolbutamide (mg per 100 ml)

glucose, have failed to explain the main hypoglycæmic effect

As well as the supporting papers cited, the large literature on this subject contains much to counter each of the two main theories of the mode of action For instance, many studies have failed to produce evidence of increased utilisation of glucose (Recant and Fischer 1957b), such as would be expected from a stimulus to the production of insulin, and, on the other hand, tolbutamide has been shown to lower the blood-glucose in hepatectomised rats and dogs (Dulin and Johnston 1957)

In the absence of any single generally acceptable theory we thought it probable that more than one type of hypoglycæmic action may occur in one person The assessment of the relative importance of such hypoglycæmic mechanisms was then our main task In this it was critical to obtain evidence that the sulphonylureas have an insulin-like action which would favour the view that insulin is potentiated or its production stimulated, and it was important to try to separate an effect on the production of glucose by the liver in the fasting state from an effect on the metabolic processes of absorbed carbohydrate Studies of our clinical material, which consisted of two contrasting types of diabetics, helped to provide information on both these aspects

TABLE IV—RESULTS OF GLUCOSE-TOLERANCE TESTS WITH AND WITHOUT TOLBUTAMIDE IN STABLE DIABETES

—	Control G-T T without tolbutamide	G-T T 3 hours after administration of tolbutamide 3 g
%Fall in fasting venous blood-sugar		25 6 (15)
Mean capillary/venous blood-sugar difference (mg per 100 ml)	12 8 (13)	14 0 (15)
%Fall in serum-phosphorus	9 9 (13)	12 7 (14) p=0 4
%Fall in serum-potassium	9 6 (9)	8 1 (7)

Numerals in parentheses indicate number of persons from whom the mean was derived

Clinical Studies

GROUP 1

The first group consisted of thirteen diabetics selected because they were likely to show a good hypoglycæmic response to the sulphonylureas, and in the event each did They were older stable diabetics with no tendency to ketosis, of whom none was grossly overweight, and some were under average weight The investigation of this group was planned to seek evidence of any hypoglycæmic action attributable to the release of insulin following the administration of the initial dose of tolbutamide We, like Goetz et al (1956) and Mirsky et al (1957), considered that the initial action of tolbutamide might be mediated mainly by the release of insulin, but that, after long-continued administration, the hypoglycæmic effect was less likely to be attributable to increased production of insulin We therefore repeated the study of the effects of a test dose of tolbutamide after it had been administered continuously for several weeks or months in 4 of the patients

Method of Investigation

The trial was planned to use the diabetic patient for bioassay of insulin by measuring changes which could be regarded as typical of the known actions of the hormone (1) an increased difference between capillary and venous blood sugar levels (method of Nelson 1944, Somogyi 1945), (2) a fall in the level of inorganic phosphorus in the serum (method of Fiske and Subbarow 1925), and (3) a fall in the serum potassium level (Internal Standard flame photometer) during an oral glucose-tolerance test Control data were obtained by measuring these changes in the patient while on no treatment during a glucose-tolerance test lasting 2½ hours after the administration of glucose 50 g by mouth The test data were obtained by repeating the procedure 3 hours after tolbutamide 3 g had been given by mouth The six samples of venous blood obtained in each case were collected, when feasible, without using a tourniquet, and both venous and capillary blood-sugar levels were estimated in duplicate Care was taken to avoid hæmolysis in the specimens used for estimating inorganic phosphorus and potassium

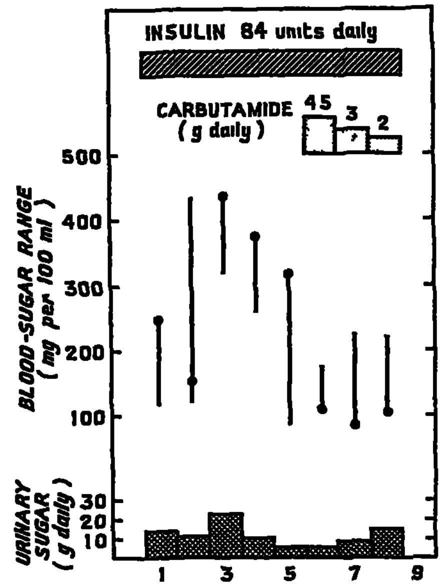

Fig 4—Response of blood-sugar, measured at three different times of the day, to carbutamide in a "brittle" diabetic

Blood-sugar levels were measured fasting (●), 3 hr after lunch, and 2 hr after supper On treatment with carbutamide the fasting blood-sugar, previously the highest in the daily range, became the lowest Patient was a man, aged 25 and weighing 55 kg, on a 2000-calorie diet

Results

The results are shown in table IV The mean fall in the

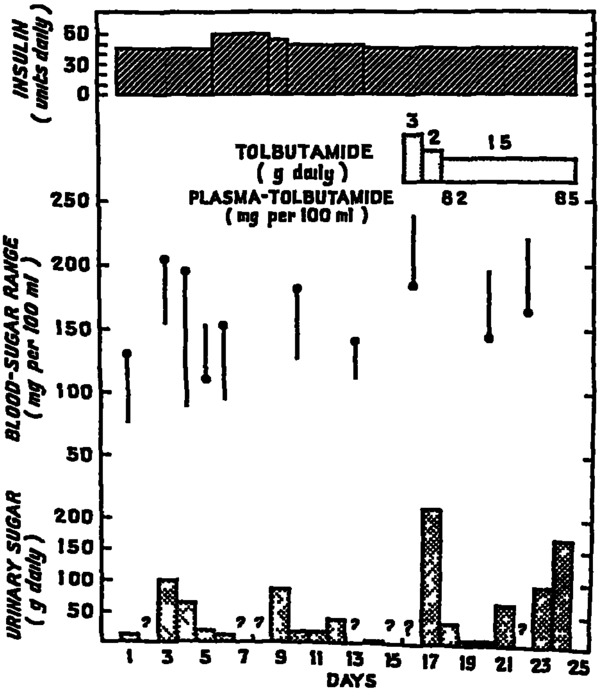

Fig 5—Response of another "brittle" diabetic to tolbutamide

Here too the fasting blood-sugar (●) became the lowest in the daily range during the administration of tolbutamide, although previously the fasting blood-sugar level was usually highest in the daily range Patient was a man, aged 43 and weighing 54 5 kg, on a 2000-calorie diet.

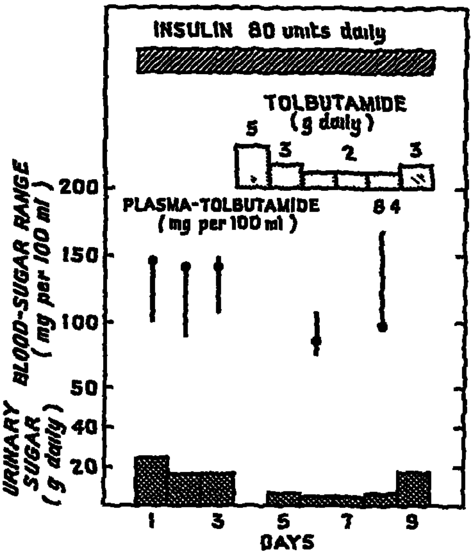

Fig 6—Response of "brittle" diabetes to tolbutamide shown by fasting blood-sugar level (●) in a woman, aged 31 and weighing 43 8 kg, on a 2200-calorie diet

fasting venous blood-sugar level 3 hours after administration of tolbutamide 3 g, compared with that on the day of the control glucose-tolerance test, was 25 6% The remaining data can be used to indicate whether this fall was due to the action of endogenous insulin Thus the mean difference between capillary and venous blood-sugar levels in specimens drawn on six occasions in each glucose-tolerance test was 12 8 mg per 100 ml in the control glucose-tolerance tests and 14 mg per 100 ml in the tolbutamide glucose-tolerance tests The capillary/venous difference in the control test suggests that these diabetics did not totally lack insulin, but tolbutamide did not significantly increase the difference between capillary and venous blood-sugar levels as would have been expected with increased action of insulin at the periphery The lack of any significant increase in the fall of serum-inorganic-phosphorus after administration of tolbutamide (12 7% compared with 9 9% in the control, $p=0\ 4$) also shows no evidence of any increased action of insulin at the periphery The failure to find any significant increase in the fall of serum-potassium after administration of tolbutamide is in keeping with the other data indicating no increase of insulin effect

Studies on these stable diabetics confirmed that the main action of tolbutamide was on the fasting blood-sugar level. The shape of the glucose-tolerance curves and the timing of the fall of serum-inorganic-phosphorus and serum-potassium were not affected Plasma-tolbutamide levels obtained during the tests were as high as 32 mg per 100 ml When the tolbutamide-tolerance test was repeated after several weeks or up to more than 2 months in four patients, the fasting venous blood-sugar level was even lower than in the first tolbutamide test, but there was no tendency towards greater capillary/venous blood-sugar differences or a greater fall in serum-inorganic-phosphorus

GROUP 2

The second group consisted of fifteen diabetics selected because they were typically unstable or "brittle" They were known to show wide variations between ketosis and hypoglycæmia and were all young or middle-aged adults None was obese The daily insulin dosage extended from 48 to 124 units (mean 78 units) in different patients Six of the fifteen had renal glycosuria, the renal threshold for sugar being about 140 mg per 100 ml or lower This had doubtless contributed to the brittleness of the diabetes because of the tendency to assess insulin dosage on qualitative tests for urinary sugar

The study was designed to answer the following questions (1) Would the sulphonylureas decrease the requirement for insulin? (2) Would they make the diabetes more stable? (3) Would brittle diabetes react differently from mild stable diabetes?

Method of Investigation

All except two of the fifteen were admitted to the ward but were ambulant They were given a diet of constant calorie value and then stabilised on insulin alone Capillary blood-sugar levels were measured in duplicate by the Nelson-Somogyi method at 8 A.M, 4 P.M, and 8 P.M for a control period of 3 to 20 days The times at which blood samples were collected represented fasting, 3 hours after lunch, and 2 hours after supper Total daily sugar excretions were measured (Somogyi 1941) Carbutamide or tolbutamide was then added to the regime in two daily doses The quantity given was usually 3 g on the first day, 2 g on the second day, and then 1–2 g daily for maintenance The estimations of sugar in the blood and in the urine were then continued for 3 to 16 days These results were then compared with those obtained in the control period

Results

Although many of the patients were well balanced in the control period, with blood-sugar levels within the normal non-diabetic range, in no case did carbutamide or tolbutamide, when added to the regime, induce clinical hypoglycæmia The blood-sugar levels were not in fact significantly lower when

TABLE V—BLOOD-SUGAR LEVELS BEFORE AND DURING SULPHONYLUREA THERAPY IN BRITTLE DIABETES

Numerals in parentheses indicate number of determinations used in calculating mean these hypoglycæmic agents were given, except for the fasting blood-sugar level in six of the eleven cases in which suitable data were obtained Three such cases are illustrated in figs 4–6 Some patients had their lowest blood-sugar at 8 A M in the control period and thus could not show the sort of change illustrated in these three figures Since the fasting blood-sugar level of a diabetic is determined by the hepatic glucose output, we conclude that carbutamide and tolbutamide lowered the fasting blood-sugar level in some of these brittle diabetics by significantly decreasing the output of glucose from the liver

The stability of nine of these diabetics has been analysed by comparing the standard deviations from the mean blood-sugar levels at three different times in the day in the control period and when receiving carbutamide or tolbutamide The results are shown in table V There was a decrease in the standard deviation from the mean blood-sugar level at each of the three different times in the day when taking the hypoglycæmic agent except in one patient, and no significant change at one of the three times in one other patient It is concluded that tolbutamide and carbutamide lessened the variations in blood-sugar levels in eight of nine of these brittle diabetics, and this happened not only in the fasting state but also in the 2-hour and 3-hour postprandial states In only one instance did this increased stability offer any easily apparent clinical advantage.

The daily excretions of sugar, compared with the corresponding blood-sugar levels, do not suggest that tolbutamide and carbutamide significantly altered the renal threshold for glucose No toxic effects of any kind were seen in these groups of diabetics during treatment

Conclusions

Since administered insulin was not rendered more effective by carbutamide or tolbutamide, except possibly in the fasting state, we think it unlikely that these drugs inhibited the destruction of the insulin given The results are consistent with the theory that the drugs inhibited output of glucose by the liver Although the brittle diabetics were not of the type usually thought to respond to the sulphonylureas, and fell indeed into the category of diabetics probably lacking insulin of their own, nevertheless both carbutamide and tolbutamide lowered the fasting blood-sugar in six out of eleven patients and decreased the variations in blood-sugar levels in eight out of nine These actions are therefore unlikely to be attributable to any stimulus to production of insulin

In conclusion, sulphonylureas appear to decrease to an important extent the hepatic output of glucose in both stable and the contrasting unstable diabetics Our data do not exclude the possibility of a stimulus to the secretion of insulin, particularly if sulphonylureas were to have more effect on the action of insulin on the liver than elsewhere, as has been suggested by Frawley et al (1957), but our data did not yield evidence to support this

Summary

Tolbutamide was distributed in a volume corresponding to 15–25% of the bodyweight, equivalent to the extracellular fluid, and carbutamide had about double this volume of distribution

Carbutamide persisted in the body more than four times as long as tolbutamide, which should therefore be given at least twice a day

Up to 28% of “ tolbutamide ” estimated in plasma was found to be in the form of its physiologically inactive carboxylic ester

Clinical studies of the kidney’s action on tolbutamide are reported

Explanations of the mode of action of the sulphonylureas are reviewed briefly, and studies of their action in a group of stable and a group of unstable diabetics are reported

We conclude that the sulphonylureas significantly reduced the output of glucose from the liver in both groups of diabetics and that they decreased the variation in the blood-sugar of most of the unstable ones

No evidence of increased secretion of insulin was obtained

Valuable assistance from Dr W T Strauss, of Arbroath Infirmary, from the house physicians and ward sisters of the professorial units of Maryfield Hospital, and from the patients themselves is gratefully acknowledged Biochemical assistance was given by Miss J Peters, supported by a grant from British Insulin Manufacturers, and by Miss L. W Constable, B.SC., and W C Love, M.SC., both supported by the Scottish Hospital Endowments Research Trust. Prof I G W Hill is thanked for his support in this work. The British Insulin Manufacturers supplied the carbutamide and tolbutamide.

THE FŒTAL LOSS IN PREGNANCY TOXÆMIA

T B FitzGerald
D S C, M.B Birm, F.R C S.E, M R C O G
CONSULTANT GYNÆCOLOGIST

A D Clift
M B Manc.
LATELY SENIOR HOUSE-SURGEON
ASHTON-UNDER-LYNE GENERAL HOSPITAL, LANCS

Though pregnancy toxæmia still carries a serious risk for the mother, we can now, without increasing that risk, give more consideration to the fate of the baby The loss of child life from this cause remains very great

In a review of 819 cases of toxæmia in the hospital for the past five years it has proved quite easy to separate out 72 in which stillbirth or neonatal death was mainly or entirely due to the toxæmic process Clinically these fell into four groups

Group 1 intrauterine death.
Group 2 accidental hæmorrhage
Group 3 intrapartum death
Group 4 neonatal death

“ Intrauterine death ” includes only death of the fœtus in utero before the onset of labour and not as a result of accidental hæmorrhage

Table I shows the numerical distribution in these groups This simple breakdown brings out the importance

TABLE I—LOSS OF FŒTUS IN PREGNANCY TOXÆMIA

Group 1 intrauterine death	Group 2 accidental hæmorrhage	Group 3 intrapartum death	Group 4 neonatal death	Total
29 (*40%*)	19 (*26%*)	14 (*19·4%*)	10 (*14%*)	72

of intrauterine death which forms the largest single group In their much bigger series Hamilton, Jeffcoate, and Lister (1949) found that the same proportion of the total fœtal loss lay in this group

Groups 1 and 2 not only are the largest numerically but also seem likely to have common lethal factors with groups 3 and 4 In a previous review of intrapartum fœtal death FitzGerald and McFarlane (1955) found that toxæmia did not show as great an effect as was expected In the present series the considerable incidence of antepartum death suggests that this may be due to the removal of potential cases from the field before labour begins

The greater incidence of intrauterine death in primigravidæ and of accidental hæmorrhage in multigravidæ is well recognised (table II)

Table III roughly indicates the efficacy of orthodox hospital treatment, it suggests that this is more successful in the avoidance of accidental hæmorrhages than in the prevention of intrauterine death, for in the latter group there is little difference between the booked and the non-booked cases

TABLE II—EFFECT OF PARITY ON FŒTAL LOSS IN PREGNANCY TOXÆMIA

—	Total	Intrauterine death	Accidental hæmorrhage	—
Primigravidæ	43	45%	19%	Percentage of total primigravid loss
Multigravidæ	29	34%	41%	Percentage of total multigravid loss

Birthweights

An important contrast between these two groups of fœtal deaths is provided by a study of the birthweights It is well recognised that the children of toxæmic mothers tend to be small, but the importance of this observation has been obscured by consideration of the birthweight in relation to an artificial prematurity standard of 5¹/₂ lb We suggest that the important relationship is that between the birthweight and some reasonable standard of what the weight should be at that particular stage of gestation This should give a realistic picture of any stunting of fœtal growth as a result of the toxæmia Recently Baird et al (1957) have pointed out the type of case where fœtal growth is retarded and intrauterine death takes place

Figs 1 and 2 show the birthweights in cases of intrauterine death and accidental hæmorrhage, and fig 3 shows curves obtained from these diagrams superimposed on a curve of normal fœtal weights at varying gestation periods, obtained from the work of Clatworthy and Anderson (1944) which was based on the studies of Streeter (1920) Fig 3 shows clearly that it is the cases of intrauterine death which are most affected by this stunting of fœtal growth, the curve of accidental hæmorrhage approximates much more closely to the normal, the curves actually meeting at 35 weeks' gestation

TABLE III—EFFECT OF TREATMENT

—	Total	Intrauterine death	Accidental hæmorrhage	—
Booked	39	38%	10 8%	Percentage of total booked loss
Non-booked	33	44%	40%	Percentage of total non-booked loss

From a consideration of these points the suggestion emerges that there are two different ways in which fœtal death takes place in pregnancy toxæmia In one group growth is diminished or ceases and the baby " fades out " as an intrauterine death without any clearcut exacerbation of the toxæmia, presumably as a result of failure to obtain sufficient oxygen or nutrients In the other group placental function remains more or less adequate, allowing more normal fœtal growth, until there is an abrupt interference with the oxygen supply by the stripping of the placenta from its bed by hæmorrhage

It is now established that, in many cases of pregnancy toxæmia, there is a defective blood-supply to the placental bed owing to spasm of the arteries supplying the uterus This would explain intrauterine death associated with stunting of fœtal growth May it not be that in other cases this spasm of the uterine arteries is absent or diminished, thus permitting normal nutrition and growth of the fœtus but allowing the effects of the generalised hypertension to be transmitted to the vessels supplying the placental bed, with resultant retroplacental hæmorrhage in a proportion of cases? The existence of the two types of case—i e, with and without spasm of the uterine arteries, is supported by the atypical results obtained in some of the cases investigated with radioactive isotopes for the efficiency of the uterine circulation in toxæmia, and by similar discrepancies in cases of toxæmia where the placental function has been deduced from its output of hormones (Russell 1957)

Perhaps the most graphic illustration is seen in two toxæmic cases examined for adequacy of placental function by Clayton et al (1956) using radiosodium and a scintillometer In one case intrauterine death took place at 34 weeks with the delivery of a fœtus weighing 2 lb 13 oz The uptake of radiosodium, indicating " placental efficiency," was grossly deficient in three estimates shortly before the fœtus died By contrast, in a second case, the patient showed fairly severe toxæmia at 39 weeks, but placental function estimated at this time showed little change from normal

Treatment

Any considerable improvement in treatment may be impossible until more is known about the cause of the toxæmia Meanwhile advances can come only from better application of present methods

Dieckmann and Brown (1939) formulated a general principle of treatment as follows

> " Over 60% of the fœtal and neonatal mortality in toxæmia patients occurred with the fœtuses weighing 1,000 to 2,000 grams Since maternal toxæmia has no further effect on the fœtus once it is born the treatment of the mother should be directed to prolonging the pregnancy as long as it is compatible with her best interests to obtain as old and as heavy a baby as possible "

This principle usually leads to the attempt to maintain the pregnancy until the 37th week of gestation, and the success of this policy must depend on the avoidance of accidental hæmorrhage and intrauterine death during that time The results in the present series suggest that, though it is to some extent successful in preventing accidental hæmorrhage, it does little to prevent failure of fœtal growth followed by death in utero

Again, if this policy of waiting is to succeed, there must be some reasonable warning if and when fœtal growth

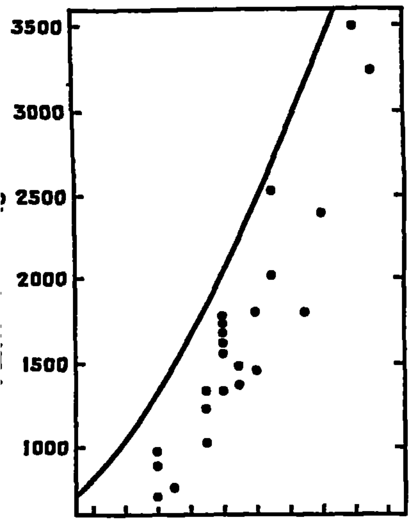

Fig 1—Birthweights in intrauterine deaths, and curve of normal growth

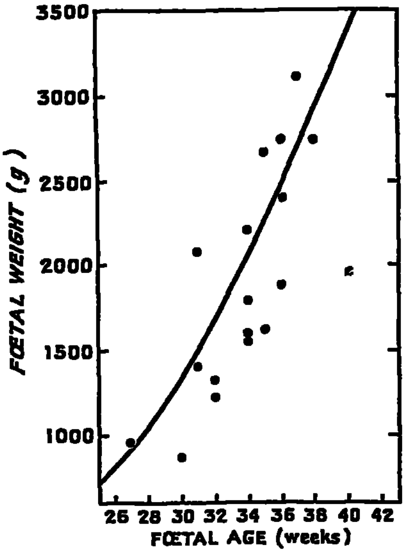

Fig 2—Birthweights in accidental hæmorrhage, and curve of normal growth

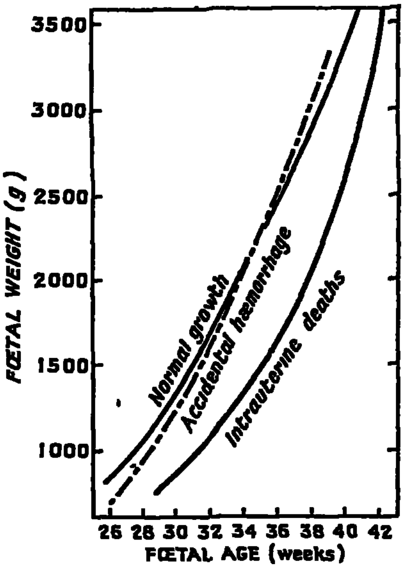

Fig 3—Comparison of figs 1 and 2 with normal fœtal weights

is failing Examination of case-records does not reveal any consistent signs of worsening of the toxæmia The records bring out the great importance of noting evidence of failure of fœtal growth in those cases which terminated in death in utero, and show that insufficient attention had been paid to these signs References to the importance of this clinical observation are not very common Townsend (1955) emphasised this point, and other workers agreed with him

The failure of fœtal growth may be recognised by the observation that the height of the fundus is much below that expected from the history If a more careful watch is kept, it should be possible to note the failure of the fundus to rise in successive weeks In 19 of the 29 cases of intrauterine death considered here the fundus was noted as distinctly low for the dates, and in 5 cases failure to enlarge was noted In 3 cases where X-ray examination for maturity was undertaken, there appeared to be an associated delay in the appearance of the ossification centres This might lead to a mistaken rejection of the patient's last menstrual period as a basis for calculation

It has been suggested that the presence or absence of albuminuria may be of special significance in differentiating cases in which intrauterine death is likely, but this is doubtful Albuminuria was present in 26 of the 29 cases of intrauterine death and in 16 of the 19 cases of accidental hæmorrhage The presence of albuminuria would therefore not assist in indicating which form of trouble might be anticipated 109 babies born alive of toxæmic mothers weighed less than $5^{1}/_{2}$ lb, only 13 of these had a normal birthweight relative to maturity, and 10 had albuminuria Of the 86 babies with a low birthweight relative to maturity 25 had no albuminuria These figures show that albuminuria is no reliable guide to those babies who are stunted in growth

Fig 4 shows the times of occurrence of accidental hæmorrhage and of intrauterine death, nearly 90% of the former and 70% of the latter occurred before the 37th week of gestation Obviously it cannot be argued that earlier induction would save all these babies, for some would then be lost from prematurity and the hazards of induction Nevertheless these results suggest caution in the policy of allowing the pregnancy to proceed, particularly if there is evidence of failure to grow Hamilton et al (1949) found results curiously little influenced by methods of delivery, but the timing seems to be of even greater significance than the method These authors also found that cæsarean section offered the best chance of survival to babies weighing less than 4 lb, and we believe that this applies particularly to the small starvelings of toxæmia

The following brief case-reports illustrate how treatment, where there is failure of fœtal growth, may be influenced by these various considerations

Case 1 —Mrs A, aged 29, primigravida, had taken four years to conceive She was seen as a consultation at the 32nd week Blood-pressure 170/100 mm Hg, urine clear, fundus uteri at 24 weeks' level She was admitted forthwith rest and reserpine stablised her blood-pressure at about 150/90, with a trace of albuminuria intermittently The patient was quite sure of her menstrual dates, but ten days before the expected date of delivery based on them the fundus was at the level of only 32 weeks Radiography showed fœtal development equal to that of 30 weeks' maturity, so the pregnancy was allowed to continue to await further growth of the fœtus Nine days

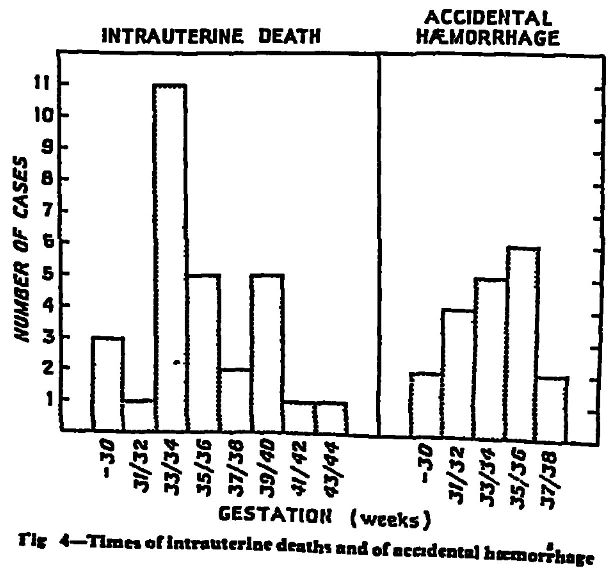

Fig 4—Times of intrauterine deaths and of accidental hæmorrhage

later the fœtal heart sounds disappeared, and six days after this a macerated infant weighing 4 lb was delivered, the placenta weighed 13 oz

This delivery took place about two months after admission to hospital, and there had been ample opportunity to deliver a live child

Case 2 —Mrs B , aged 36, had had one miscarriage previously and had been wanting a baby for eleven years She was a booked case with essential hypertension admitted at 36 weeks after her last menstrual period because of continuing mild hypertension with sudden increase of weight and œdema The level of the fundus was that of a 32 weeks' gestation and X-ray examination at this time suggested 32 weeks' maturity The blood-pressure was stabilised at 140/90, with a slight trace of albumin on two occasions only About a week after admission the fœtal heart showed some irregularity and tachycardia, and in view of this and the failure of the baby to grow a cæsarean section was performed in the 38th week of gestation, reckoning from the patient's last menstrual period, of which she was quite confident A living child weighing 4 lb 11 oz was delivered and survived satisfactorily

This patient occupied the next bed to that of case 1, and the first tragedy undoubtedly influenced the more active policy in this case

Case 3 —Mrs C , aged 43, primigravida, was admitted as an emergency with severe toxæmia, blood-pressure 160/100 and heavy albuminuria at the 39th week of gestation, the level of the uterine fundus was that of 32 weeks After twenty-four hours' rest and heavy sedation cæsarean section was performed and a small "starveling" baby was delivered weighing 3 lb 11 oz Radiography of the baby seven days after delivery showed a fairly well developed astragalus but no epiphysis at the lower end of the femur, so the age appeared to be between 33 and 35 weeks

Once again the radiological evidence clashed with that of the patient's menstrual dates The infant gave rise to considerable anxiety at first, but survived satisfactorily It is very doubtful if this would have been the result if an attempt had been made to hold off delivery to allow further growth of the child

Summary

The chief causes of fœtal loss in toxæmia are accidental hæmorrhage and intrauterine death before labour

Evidence is produced suggesting that whereas in some cases placental function remains adequate allowing fairly normal fœtal growth until there is a retroplacental hæmorrhage, in others the fœtus "fades out" because spasm of the uterine arteries reduces its supply of oxygen or nutrients

Provided accidental hæmorrhage can be avoided, the policy of maintaining pregnancy till the 37th week may be successful in the first group of cases, but it is unsuccessful for those in which failure of fœtal growth is followed by death in utero

A close watch should be kept for evidence that the fœtus is not enlarging normally

The timing of delivery may be of more importance than the method

ORIGIN OF PERIPHERAL TUBERCULOUS LYMPHADENITIS IN CHILDHOOD

The relation of peripheral tuberculous lymphadenitis to primary tuberculous infection is still a matter of discussion and comment (American Trudeau Society 1954) Though mediastinal or mesenteric tuberculous lymphadenitis is usually accepted as evidence of a primary infection in the respective drainage area, this is not true of inguinal or preauricular adenitis and not always of cervical adenitis

We became interested in the origin of peripheral tuberculous lymphadenitis, and its relation to the primary tuberculous infection, while we were studying the recognition of primary foci in the skin or mucous surfaces (Miller 1953) and the natural history of the related tuberculous lymphadenitis (Miller and Cashman 1955a) With the experience gained in this and other studies we thought we could usefully review all the children seen in our department from 1947 to 1952 who had been diagnosed and treated as having peripheral tuberculous lymphadenitis

We asked this question Is peripheral tuberculous lymphadenitis, wherever it presents, likely to be part of a primary complex, or does it arise by hæmatogenous spread from a primary focus in the lung or alimentary tract ?

Children Studied

Between 1947 and 1952, tuberculous infection in a group of superficial glands was diagnosed in 338 children Coming in the ordinary course of clinical work, the children were seen at all stages of the tuberculous infection and only those with a visible primary focus were studied initially as a special group Of these we excluded all who had not had a complete radiological examination (neck, chest, and abdomen) when first seen, and all who could not be traced for a second radiological and clinical examination at least two years afterwards This radiological examination was necessary to judge the probable duration of infection in the glands We were left, therefore, with a group of 163 children, of all ages to 15 years, known to have tuberculosis, who had radiological records in addition to clinical notes and were examined again at least two years after they presented at hospital The diagnosis remained in doubt in only 6 children, who had a positive tuberculin skin test and enlarged glands which neither softened nor calcified

We have previously shown that

> In children with recent tuberculous infection of the inguinal, axillary, or cervical glands (except the tonsillar), careful examination will sometimes reveal a primary focus on the skin or mucous surface drained by the glands (Miller 1953)
>
> The primary focus usually leaves a characteristic scar, but in certain circumstances may disappear without trace (Boyes, Jones, and Miller 1956)
>
> The peripheral glands draining a primary focus on skin or mucous membrane usually show radiological calcification within two or three years of infection In most cases, this calcification is the only residual sign of tuberculous infection

THE ANATOMICAL DISTRIBUTION IN, AND THE CLINICAL GROUPING OF, 163 CASES OF PERIPHERAL TUBERCULOUS LYMPHADENITIS

Group of lymph-glands involved	Children with a known time of infection—all with unilateral gland enlargement					Children without known time of infection					
						Unilateral					
	Visible primary focus	Tuberculin conversion observed	Tuberculin conversion under 1 yr of age	Conversion with erythema nodosum	Conversion with "fever" of onset	Without calcification when first seen	With calcification when first seen	Glands showing calcification without abscess formation	Bilateral enlargement	Cases of special interest	Total
Preauricular	10									1	11
Postauricular	1										1
Occipital	1										1
Submental	3										3
Supramandibular	1										1
Axillary	3									1	4
Epitrochlear										2	2
Inguinal	13								*1	1	15
"Supraclavicular"				1		1	2		1	2	7
Tonsillar	9	4	7	3	10	26	26	9	16	2	118
Submandibular	6										
Total	47	25				27	28	9	18	9	163

* Also with a visible primary focus

(Miller and Cashman 1955a) Calcification may spread to other glands in the line of lymphatic drainage.

When children undergo primary infection the site of infection can be demonstrated in at least four-fifths of cases if examination is sufficiently careful and observation long-continued (Miller 1956)

It is a matter of clinical experience that in children in this country the glands draining a hæmatogenous deposit, such as a joint or a metastatic abscess, rarely if ever become clinically enlarged or proceed to abscess formation.

If these facts are accepted, it follows that any group of tuberculous lymph-glands (wherever they arise) are likely to represent the gland component of a primary complex if they are the *sole* clinical or radiological sign of tuberculosis in the body

Results of Review

From the history and the results of clinical and radiological examination of the 163 children, we were able to group them as in the table

Occasionally in the original clinical records there was some difficulty in distinguishing between tonsillar and submandibular lymphadenitis, this applied to only a few cases, but we have taken these two sites together (at least 9 of every 10 were tonsillar) No child in this series had generalised tuberculous lymphadenitis, which must be extremely rare in English children We did see 2 children with bilateral cervical adenitis which became evident some years after primary pulmonary infection They form an uncommon but very interesting and puzzling type of cervical lymphadenitis and we refer to them later

We shall now consider the various topographical groups of glands, to determine how many were the only sign of tuberculosis (and therefore likely to be part of a primary complex), and to discover the evidence, if any, that the infection might be hæmatogenous ✓

Preauricular Glands (11 children) ✓

5 of these had primary foci on the skin of forehead or cheek, 3 on the palpebral conjunctiva of the upper eyelids, and 2 in the lacrimal sac. None had hæmatogenous lesions or calcification in any other group of glands We did not find a primary focus in the 11th child, and his tuberculous lesion was a small abscess on the cheek just above the angle of the jaw Though we cannot be sure we think that this was more likely to be a subcutaneous abscess than a preauricular adenitis (Miller and Cashman 1955b) Even at the follow-up examination we could not demonstrate the site of the primary complex

Other Glands Draining Face and Scalp (6 children) ✓

In each case a primary focus was found 1 in the scalp draining to occipital glands, 1 in the mouth to the supramandibular gland, 1 on the scalp to postauricular glands, and 3 on the chin to the submental glands The first child had miliary tuberculosis when he was first seen with the occipital adenitis, but he made a good recovery and did not have any other lymph-gland involvement. No other child had hæmatogenous lesions or calcification in any other group of glands

Axillary Glands (4 children) ✓

3 of these had primary lesions visible on the arm and tuberculous axillary adenitis without other manifestations of tuberculosis The 4th case was not so readily explained The child had a tuberculous abscess on the anterior wall of the axilla without any other signs of tuberculosis We think that, like the boy with the abscess on his cheek, she may have had a metastatic abscess, but again we have no evidence of the site of primary infection.

Epitrochlear Adenitis (2 children) ✓

We think both these children were inaccurately diagnosed 1 had a subcutaneous abscess on the inner aspect of the arm and a primary complex in the lung, the other had a lesion, described as an epitrochlear abscess, which was indeed a primary focus with an axillary adenitis and no other evidence of tuberculosis In both children the epitrochlear gland was intact.

Inguinal Adenitis (15 children) ✓

13 of these children had visible primary foci on the skin of foot, leg, or buttock The only child with bilateral inguinal adenitis had a primary lesion at the anus but crossing the midline to drain to both inguinal areas Not one of these 14 children had any other sign of tuberculosis The 15th child presented with an inguinal adenitis and a calcifying primary complex in the lung When she was first seen a small scabbed lesion was noted in the skin over the tendo achillis, but unfortunately was not further examined Two years later there was calcification in the inguinal gland and a small scar typical of a primary focus on the skin at the site of the original scab This girl almost certainly had a double primary infection—one complex in the skin and inguinal glands the other in the lung and mediastinal glands

Supraclavicular Adenitis * (7 children) ✓

Supraclavicular adenitis, unlike the adenitis in those groups just discussed, was not associated with visible primary foci But 4 children had mediastinal calcification and a 5th mediastinal and mesenteric calcification The association is clear but the mechanism is not so obvious, as well as draining to the

---

* There is some difficulty about terminology The glands are those described in Gray's Anatomy [illegible] ed, pp [illegible], as subclavicular or inferior deep cervical, but clinically they present as masses just above the clavicle We have preferred to call the lesion 'supraclavicular adenitis'

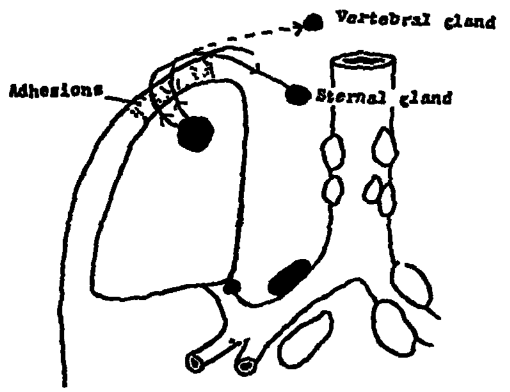

Fig 1—Drainage of apical primary focus to the sternal and vertebral glands in addition to the mediastinal glands (Scott and Beattie 1928)

mediastinal glands the infection from an apical primary focus might have spread through the apical pleura to the supraclavicular glands as described by Scott and Beattie (1928) (fig 1) A 6th child had a chain of calcification reaching down from the tonsillar gland, and the supraclavicular mass in this case was the lowest gland in the chain, yet for some reason it softened first The 7th child presents a difficult and as yet unexplained problem A strong healthy boy of 12 years presented with a large firm swelling above the medial end of the *right* clavicle (fig 2) The only other sign of tuberculosis was a small rounded lesion at the extreme apex of the *left* lung with slight hilar adenopathy The mass above the clavicle soon softened and was removed surgically, healing was quick Calcification can now be seen at the left apex and hilum of the lung, but *not* above the clavicle

It seems likely that he had a primary complex in the left upper lobe Direct spread to the *right* supraclavicular glands seems unlikely, and beyond suggesting that infection reached the left supraclavicular glands via the blood-stream, or that it did not arise in a lymph-gland, we cannot explain this case

Tonsillar and Submandibular Adenitis (118 children)

The tonsillar group of glands is by far the commonest site of peripheral tuberculous lymphadenitis Only 16 of these 118 children had bilateral lymphadenitis, and in only 9 of the 118 has calcification appeared without abscess formation In various ways we knew the time of infection in 33 of these children but we were able to see a *primary focus in the mouth* or tonsils in only 15 children The others were seen at very varying times after infection, for glands are often present for some years before an abscess forms and the child is sent to hospital

Fig 2—Swelling caused by tuberculous abscess in supraclavicular glands or in subcutaneous tissues Only other tuberculous lesion a primary complex at the apex of the left lung

9 of the 118 children had calcification in mediastinal glands, another 17 had calcification in mesenteric glands, and 1 had calcification in both mediastinal and mesenteric glands as well as cervical glands In all, therefore, 27 of the 118 children had evidence of central as well as peripheral calcification, leaving 91 in whom the cervical adenitis was the only sign of tuberculosis In this district in 1947, at least 85% of all primary infection in children was in the lung, but in these 118 children abdominal calcification was twice as common as pulmonary This distribution of calcification is almost certainly related to the manner of infection rather than to spread after infection

Although only 16 of the 118 children had bilateral tuberculous lymphadenitis, 8 of these 16 had calcification in other glands also—3 in the mediastinal, 4 in the mesenteric, and 1 in both In contrast only 19 of 102 children with unilateral calcification had other calcification This distribution again can hardly be accidental and a reasonable explanation is that when infection is heavy enough to give bilateral infection of cervical glands it is also more likely to give another simultaneous primary infection elsewhere

4 of these 118 children merit special mention

2 children with enlargement of cervical glands were found to have old abdominal calcification In one the cervical glands progressed to abscess formation and tubercle bacilli were recovered, in the other calcification appeared some two years later, and eventually these glands also softened The relationship of the tuberculous infection of these groups of glands is not clear because there seems no reason why mesenteric calcification should appear before cervical if the children had simultaneous oropharyngeal and abdominal primary infection. Yet we have already mentioned a very similar case of the girl who had a calcified complex in the lung and an inguinal adenitis which did not show calcification until two years later

The 2 others are even more puzzling They were both children who had been infected during infancy, and when first seen each had an old and well-calcified primary complex in the lung When 8 years old they both developed extensive tuberculous infection in the cervical glands The first child had a supraclavicular abscess on the right side and a large mass of tonsillar glands on the left, and the second had a chain of rubbery glands along both sternomastoid muscles, in the tonsillar, submandibular, and submental glands, and in both axillary glands No other glands were clinically enlarged and none apart from those mentioned above have calcified

These 2 children present such difficult problems that they need separate description, but they seem to represent a type of peripheral adenitis distinct from all others in this present series, and one which is uncommon in childhood

Discussion

The series comprised 163 children with superficial tuberculous swellings diagnosed originally as peripheral lymphadenitis After our review we think that in 4 of these children the superficial swellings were metastatic abscesses rather than lymph-gland abscesses In 127 (80%) of the remaining 159, the peripheral lymphadenitis was the only evidence of tuberculosis found over a long period of observation We think that in those children it represented the gland component of a primary complex and reflected the site of the primary infection The primary focus was seen in only 48 of the children and is much more likely to be seen in children with inguinal, axillary, or preauricular adenitis than in those with tonsillar adenitis

The remaining 32 (20%) children had calcification in " central " glands as well as peripheral tuberculous lymphadenitis In 28 of these the central calcification was associated with tonsillar adenitis In this group there was at least the possibility that the peripheral adenitis was the result of hæmatogenous spread from the central glands But there are several pieces of indirect evidence which together suggest that this is unlikely

12 of the 159 children had undoubted hæmatogenous lesions, but none of these had central as well as peripheral calcification

If the peripheral adenitis had followed hæmatogenous spread, the distribution of the central primary complexes should have been the same as in the general population We have already seen that in our group mesenteric calcification was twice as common as mediastinal, whereas in the general population at that time lung primary infection was at least five times as common as abdominal infection. This very unusual distribution in our group suggests a relationship with the mechanism of infection rather than events after infection

In several of the 32 with both central and peripheral calcification there was more direct evidence that the peripheral lymphadenitis was not the result of hæmatogenous spread Thus 2 children had a visible primary focus on the skin in relation to the peripheral adenitis, in another 5 seen during the initial fever of primary infection the peripheral lymphadenitis appeared as the child became tuberculin-positive

We therefore think that multiple simultaneous primary infections must occur, and we suggest that the ingestion of infection is the explanation of the association of cervical and mesenteric calcification. We know, too, that children in contact with infective adults occasionally get a primary infection in the oropharynx and a simultaneous pulmonary primary complex by inhalation

Hence simultaneous primary infection seems to be at least as good an explanation as hæmatogenous spread in most of these 32 children with peripheral and central calcification From this statement we must, however, exclude certain of our cases of special interest, and in particular the 2 children whose cervical lymphadenitis did not arise until some years after this primary infection in the lung

From this analysis we conclude that, in English children for the period under review, at least 80% (and probably well over 90%) of all peripheral tuberculous lymphadenitis represents the gland component or the direct lymphatic drainage of a primary complex

Summary

We have presented the results of a review of 163 children with superficial swellings diagnosed as tuberculous lymphadenitis 4 of these swellings appeared to be superficial tuberculous abscesses rather than lymph-gland infections In 127 (80%) of the remaining 159, the peripheral adenitis was the only sign of tuberculosis In 32 (20%) there was calcification in mediastinal or mesenteric glands as well as peripheral tuberculous lymphadenitis, we give reasons for attributing most of these to simultaneous primary infection rather than hæmatogenous spread from central to peripheral glands. We draw attention to 2 children with an unusual form of extensive tuberculous lymphadenitis arising years after a primary infection in the lung

From the Departments of Hæmatology and Pathology, Royal Infirmary and University of Manchester

IN 1946 Wachstein, by a cytochemical technique, demonstrated that alkaline-phosphatase activity in the blood-cells is almost confined to the mature segmented neutrophils Normal polymorphs contain only small amounts of this enzyme, but in acute infections and after hæmorrhage, trauma, or infarction the quantity increases considerably In chronic myeloid leukæmia, on the other hand, there is little or none of this enzyme in the white cells, whatever the stage of the disease

Valentine and Beck (1951), Valentine et al (1952), and Wiltshaw and Maloney (1955) confirmed Wachstein's findings The method used by Valentine and colleagues is more strictly quantitative than that of Wachstein phosphatase activity is determined on a plasma-free suspension of white cells and expressed in milligrammes of phosphorus liberated per hour at 37°C by 10^{10} white cells at pH 9·9 They found the mean level to be 25·8 units in health, 119·1 units in acute infections, 4·0 units in chronic myeloid leukæmia, and 82·0 units in polycythæmia vera

Our purpose here is to illustrate the value of a simple cytochemical technique in distinguishing between (1) myeloid leukæmia and (2) leukæmoid reactions involving the myeloid series of cells Such reactions are seen in a variety of diseases—e g, Hodgkin's disease, tuberculosis, carcinomatosis, polycythæmia vera, myelosclerosis, and hæmolytic anæmias

Investigation

Method

The cytochemical technique we have used is a modification of Gomori's original method for demonstrating alkaline phosphatase

(1) Fix the blood or marrow smears for thirty seconds in a mixture of 10 ml of formalin to 90 ml of absolute methyl alcohol

(2) Wash for a few seconds and then incubate for two hours at 37°C in a freshly prepared buffer substrate solution containing 30 ml of 10% sodium barbitone, 30 ml of 3·2% sodium β-glycerophosphate, 30 ml of M/10 magnesium sulphate, 45 ml of 2% calcium nitrate, and 165 ml of distilled water

(3) Rinse the slides for a few seconds in distilled water containing a few drops of 2% calcium-nitrate solution

(4) Immerse the slides in 2% cobalt-nitrate solution for five minutes

(5) Wash well and treat for ten seconds in a weak solution of ammonium sulphide (about 1 ml of ammonium sulphide to 80 ml of water)

(6) Wash well and counterstain with 2% aqueous solution of G T Gurr's safranine O for ten seconds

(7) Wash well and mount.

Control blood films of known high leucocyte-phosphatase activity and of normal blood are put through at the same time Stock solutions of 3·2% sodium β-glycerophosphate, 10% sodium barbitone, and the formalin-methyl alcohol fixative are kept at 0–4°C until they are required.

Interpretation

Alkaline-phosphatase activity is shown as black granules in the cytoplasm of the neutrophil polymorphs lymphocytes, monocytes, plasma cells, eosinophils, and all blast cells show

Disease (no of observations)	Percentage of cells with phosphatase activity					
	Strong activity		Weak activity		No activity	
	Range	Mean	Range	Mean	Range	Mean
Normals (50)	0–2	1 0	14–82	18	25–90	82 0
Chronic myeloid leukæmia (50)	0–1	1 0	0–24	6	75–100	92 0
Polycythæmia vera (50)	30–95	65 0	5–65	32	0–6	3 0
Leukæmoid reactions (17)	25–92	60 0	10–70	34	0–14	6 0

no activity, but they can be distinguished by their affinity for safranine Phosphatase activity is expressed as absent, weak, or strong (see figs 2 and 4), and an assessment is made by examining 400 consecutive neutrophil polymorphs

Results

The range and mean percentages of cells showing strong, weak, or no activity in healthy people and in patients with chronic myeloid leukæmia, polycythæmia vera, and leukæmoid reactions are shown in the table Normal polymorphs show no activity, or weak activity represented by a few small black granules in the cytoplasm Strongly positive cells show many coarse black granules, or the whole cytoplasm appears densely black Such cells are rarely seen in normal blood and were never more than 2% of the total count

In all 50 cases of *chronic myeloid leukæmia* phosphatase activity was much reduced or absent Strongly positive cells were not seen This was true at all stages of the disease, irrespective of treatment and of the white-cell count

In *polycythæmia vera* strongly positive cells were often predominant, especially when the white-cell counts were raised

17 cases of *leukæmoid reactions* involving the myeloid series were investigated, invariably they showed a high proportion of strongly positive cells The leukæmoid reactions were associated with the following diseases Hodgkin's disease (6), myelosclerosis (3), carcinomatosis (2), tuberculosis (2), acquired hæmolytic anæmias (2), and reticulosarcoma (2) In all, the cytology of the blood and the marrow, when examined by ordinary staining techniques, was identical with myeloid leukæmia, and initially leukæmia was often diagnosed

The following examples illustrate these points

Case 1—A Regular Army corporal, aged 21, had much enlarged cervical lymph-nodes Blood examination red cells 3,900,000 per c mm, hæmoglobin 11 9 g per 100 ml, platelets 125,000 per c mm, white cells 44,000 per c mm (polymorphs 91 5%, lymphocytes 2 0%, monocytes 4 5%, eosinophils 1 0%, myelocytes 0 5%, blast cells 0 5%) The marrow picture (fig 1) was indistinguishable from myeloid leukæmia, the predominant cell being the myelocyte

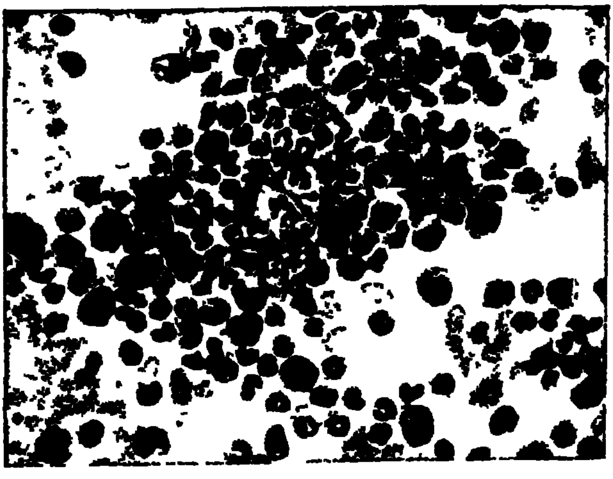

Fig 1—Case 1 (Hodgkin's disease) sternal marrow showing considerable hyperplasia of myeloid series of cells (Jenner-Giemsa)

Phosphatase test (fig 2) strongly positive 78%, weakly positive 18%, no activity 4% The high percentage of strongly positive cells was very much against the diagnosis of myeloid leukæmia Because of this a cervical lymph-node was excised, which showed typical Hodgkin's disease The patient is alive and well three years after these investigations were made

Case 2—A man of 26 had considerably enlarged cervical lymph-nodes Blood examination red cells 3,100,000 per c mm, hæmoglobin 10 1 g per 100 ml, platelets 105,000 per c mm, white cells 26,000 per c mm (polymorphs 92%, lymphocytes 6%, myelocytes 2%) The marrow smears (fig 3) were exactly like those in case 1—i e, indistinguishable from myeloid leukæmia

Phosphatase test (fig 4) strongly positive cells 0, weak 6%, no activity 94% A cervical lymph-node showed typical leukæmic infiltration The patient died two months later At necropsy there was leukæmic infiltration of his liver, spleen, skin, lymph-nodes, and marrow

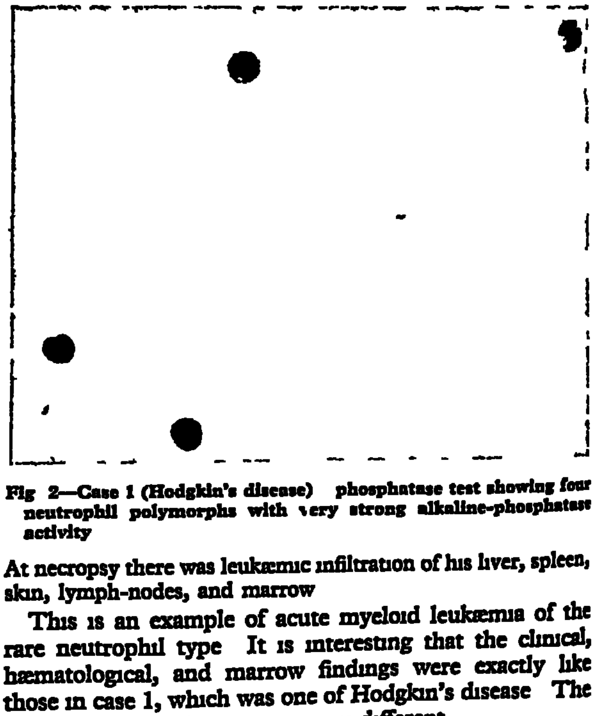

Fig 2—Case 1 (Hodgkin's disease) phosphatase test showing four neutrophil polymorphs with very strong alkaline-phosphatase activity

This is an example of acute myeloid leukæmia of the rare neutrophil type It is interesting that the clinical, hæmatological, and marrow findings were exactly like those in case 1, which was one of Hodgkin's disease The prognosis in the 2 cases was very different

The phosphatase test is usually of no value in the acute leukæmias, because blast cells contain no phosphatase However, in acute myeloid leukæmia of the neutrophil type (case 2 is an example of 2 such cases studied), where there is enough differentiation of the white cells to make the test feasible, the results are the same as for chronic myeloid leukæmia—a gross decrease of leucocyte alkaline phosphatase

Case 3—A man, aged 61, with polycythæmia vera was satisfactorily controlled for eleven years by exposures to whole-body irradiation and occasional venesection He then developed progressive enlargement of the spleen, the hæmoglobin and red cells fell slightly, and there was a considerable rise in the white-cell count, which previously had been within normal limits Blood examination red cells 5,320,000 per c mm, hæmoglobin 15 1 g per 100 ml, white cells 71,000 per c mm (polymorphs 70%, lymphocytes 5%, monocytes 5%, eosinophils 1 0%, basophils 6 0%, promyelocytes 2 5%, myelocytes 10 5%), nucleated red cells 41 per 200 white cells The blood and marrow smears were compatible with chronic myeloid leukæmia

Phosphatase test strongly positive 92%, weakly positive 6%, no activity 2% Biopsy of an iliac crest showed myelofibrosis

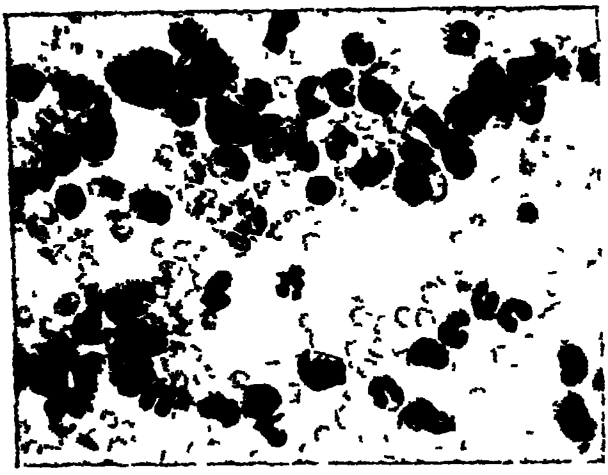

Fig 3—Case 2 (acute neutrophil leukæmia) sternal marrow showing considerable hyperplasia of myeloid series of cells. (Jenner-Giemsa.)

A splenogram confirmed a considerable extramedullary hæmopoiesis, 45% of the total nucleated cells being normoblasts of the intermediate and late types, including many in mitosis

This is an example of polycythæmia vera pursuing a long clinical course and ending in myelofibrosis, the splenic enlargement was due to extramedullary hæmopoiesis, and the white-cell changes were leukæmoid and not leukæmic. This distinction is important because radiotherapy and chemotherapy are contraindicated in the presence of myelofibrosis

Discussion

The cytochemical method of demonstrating leucocyte alkaline phosphatase, as described above, is easily applied and is often the only means of distinguishing between myeloid leukæmia and leukæmoid reactions involving the myeloid series of cells The modifications used include a different fixative, a much shorter incubation period, and a different counterstain Kaplow (1955) found that the mixture of formalin and methyl alcohol gave better cytological details than other tried fixatives

The absence or considerable reduction of leucocyte alkaline phosphatase consistently found in chronic myeloid leukæmia appears to precede any other definite cytological abnormality in the evolution of this type of leukæmia Thus, Maloney and Lange (1954) described the preclinical stage of 4 cases of myelogenous leukæmia developing in atomic-bomb survivors and found that very low alkaline-phosphatase levels in the leucocytes preceded any definite cytological evidence of leukæmia in the blood or the marrow

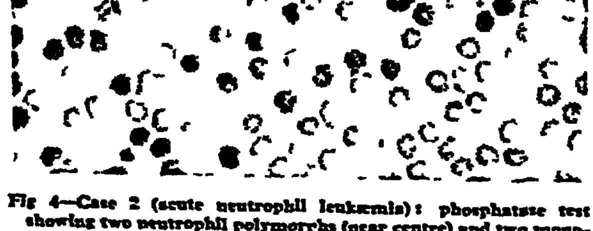

Fig 4—Case 2 (acute neutrophil leukæmia): phosphatase test showing two neutrophil polymorphs (near centre) and two mononuclear leucocytes (to left) without any alkaline phosphatase.

The leukæmoid reactions we have investigated were due to a great variety of diseases, including Hodgkin's disease, reticulosarcoma, carcinomatosis, hæmolytic anæmia, myelofibrosis, and tuberculosis They could not be differentiated from leukæmia by examining ordinarily stained blood and marrow smears, but in all of them the white-cell alkaline phosphatase was considerably increased. In the past many of these would have been classified as neutrophil leukæmias However, in 2 examples of neutrophil leukæmia which we have investigated, phosphatase studies showed a gross reduction in leucocyte-phosphatase activity It is evident that morphologically identical blood-pictures may be due to entirely different diseases and that leucocyte-phosphatase determinations are of assistance in distinguishing between myeloid leukæmia and leukæmoid reactions involving the myeloid series To establish the cause of the leukæmoid reaction it is necessary to use all the available clinical data and further assistance from histological studies—e g, by biopsy of lymph-nodes, iliac crest, spleen, &c

The precise role of alkaline phosphatase in the white cells is unknown Valentine (1956) and Valentine et al (1957) think that, in stress conditions—e g, after infection, hæmorrhage, intoxication, infarction, and trauma—there is a considerable rise in the activity of this enzyme in the white cells These stress phenomena have as their common denominator an increased pituitary-adrenal activity In normal people both cortisone and corticotrophin increase the activity of alkaline phosphatase in the leucocytes, but, when adrenal function is reduced (as in Addison's disease), though 17-hydroxycorticosteroids produce a similar increase, corticotrophin does not Valentine has also shown that, in uncomplicated rheumatic fever, rheumatoid arthritis, and some collagen disorders, there is not the expected increase in alkaline phosphatase in the leucocytes

Phosphatase was determined in 2 cases of acute leukæmia treated with cortisone in which there was complete clinical and hæmatological remission In spite of the apparent complete normality of the blood-cells, the neutrophils possessed considerably increased alkaline-phosphatase activity, which persisted until the leukæmia relapsed

Case 4—A woman of 36 was found to have acute lymphatic leukæmia Blood examination red cells 1,510,000 per c.mm, hæmoglobin 4 4 g per 100 ml, platelets 10,000 per c.mm, white cells 8200 per c.mm (polymorphs 2%, lymphocytes 34%, lymphoblasts 64%) Her marrow was considerably hyperplastic, the predominant cell being the lymphoblast. The phosphatase test did not show any activity in the white cells

After treatment with cortisone 200 mg daily for thirty-eight days there was a complete remission Blood examination red cells 4,320,000 per c.mm, hæmoglobin 14 4 g per 100 ml, platelets 265,000 per c mm, white cells 6000 per c.mm (polymorphs 68%, lymphocytes 30%, monocytes 2%)

Phosphatase test strongly positive 82%, weakly positive 12%, no activity 4% Treatment with cortisone 100 mg daily was continued and 68–94% of the neutrophils had strong phosphatase activity until the patient relapsed and died of leukæmia about three months later

Occasionally in acute leukæmias of all types an intercurrent infection causes a few strongly positive neutrophils to appear in the peripheral blood, but this was exceptional, and they never constituted more than 10% of the total count

In 2 cases of polycythæmia vera, after satisfactory control of the total red-cell mass with intramuscular injections of triethylenethiophosphoramide there was a marked reduction in the leucocyte phosphatase which lasted until the red cells started to increase in number again

With these exceptions the results have been consistent We believe that the finding of a high alkaline-phosphatase level in the leucocytes indicates the need for further clinical and pathological studies before a diagnosis of leukæmia can be made with confidence

Summary

A simple cytochemical technique for demonstrating alkaline-phosphatase activity in leucocytes is described

In chronic myeloid leukæmia and acute neutrophil leukæmia this activity is reduced or absent

In leukæmoid reactions due to Hodgkin's disease, myelofibrosis, reticulosarcoma, carcinomatosis, polycythæmia vera, hæmolytic anæmia, and tuberculosis very high levels of alkaline phosphatase were found in the leucocytes

The amount of alkaline phosphatase in the leucocytes appears to be regulated by the pituitary-adrenal axis In complete remission in 2 cases of acute lymphatic leukæmia following cortisone therapy, in spite of the apparent normality of the white cells, the phosphatase levels were high and remained so until the leukæmia relapsed

The determination of alkaline phosphatase in the leucocytes is at present the best, and often the only, means of distinguishing between myeloid leukæmia and leukæmoid reactions involving the myeloid series of cells

We wish to thank Prof A C P Campbell for his helpful criticism and for reading the manuscript Mr N Mowat, F I.M L T, kindly took the photomicrographs

SURGICAL excision of a portion of artery involves temporarily shutting off the circulation through that artery Insertion of a graft may take many minutes, and in the case of a carotid artery even a short period of occlusion is fraught with danger Even with hypothermia the time-limit of tolerance may be scarcely adequate for the task in hand, and the alternative of a temporary shunt circulation has its own difficulties

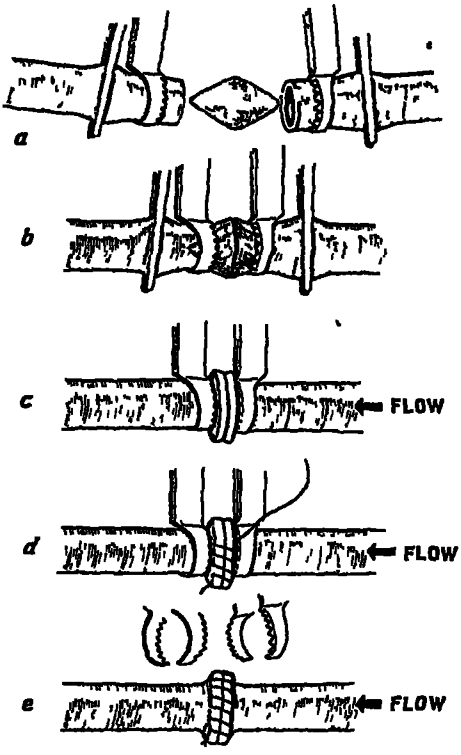

Fig 1—The ice-cone method For description see text

The problem is to join two cut ends of artery with such speed and certainty that restoration of the circulation within a few seconds can be guaranteed We felt that the solution would be found in a method permitting immediate accurate approximation of the two artery ends so that flow can take place while the ends are being sutured, and we believe that we have found such a method

The Ice-cone Method

Each of the two artery ends is placed in a toothed ring with a small portion protruding, a double cone of ice is inserted into the adjacent open ends (fig 1a), and the rings are now brought together The teeth of the rings so engage the artery wall that the cut ends must turn either outwards or inwards They cannot turn inwards, because the ice fully occupies the available space, and they are therefore obliged to flange outwards (fig 1b) When the rings are fully closed, there is between them an outward-turned flange of each artery, and the two trumpets so formed by the arteries are held firmly together by the toothed rings so that the lumen of one continues without interruption into the lumen of the other (fig 1c) Flow will start again as soon as the ice melts, at body-temperature this happens in a few seconds With the circulation restored, the flanged ends of the arteries can be sutured at leisure (fig 1d) When the suture line is completed the ring clamps are reopened and removed, this is possible because in fact each ring is constructed of two half rings which separate to allow disengagement from the artery There now remains a conventional type of anastomosis (fig 1e)

For this simple procedure to work with speed and certainty, the following conditions must be fulfilled

The rings must be slightly less in diameter than the unstretched artery—otherwise the artery cannot expand beyond the ring to form a flange, and may slip through the ring Likewise, the ice shape must have a maximum diameter slightly greater than the rings If the ring is of much smaller diameter than the artery anastomosis is still possible, but the advantages of the method are lost, because when the artery is compressed its walls are thrown into longitudinal folds, this obstructs the lumen, preventing the early flow which is the primary object of the method

The teeth must be sharp and long Small ineffective serrations cannot secure sufficient grip on the artery except by crushing it

The rings must be opposed with enough force to press the arteries against the yielding ice, so that at no time can either artery slip inside the other, but the force must not be too great or the intima will be severely nipped against the ice and fractured

To make the double cone of ice, a latex-rubber mould, of the correct size and shape, is filled with heparinised saline and placed in a container surrounded by carbon-dioxide snow, the ice cone is ready for use within an hour, and is left undisturbed until needed This process is not difficult, and when brought from the container and squeezed from its rubber mould the ice remains solid long enough for it to be used without haste All the materials to be used are sterilised at the outset

While the artery ends are brought over the ice cone, the vessels must be held and occluded by artery clamps Initially we made an instrument with ring clamps separate from the artery clamps, but this proved awkward to use because the operator was aligning three independent movable components —two artery clamps and the ring clamp , moreover, it was difficult to compete with any tension These difficulties were overcome by redesigning the instrument so that the ring-anastomosis clamp can be temporarily attached to a hinged twin set of arterial clamps

The complete apparatus consists therefore of two instruments—a ring-anastomosis clamp (stippled in fig 2a) and a twin set of artery occlusion clamps—which fit together, each assisting the action of the other

Fig 2a shows the double instrument with clamp and half rings of the left half closed as if encircling an artery, the clamp and spring-mounted half rings of the right half are open ready to place over an artery When either clamp is closed, its small side arms bring the corresponding spring-mounted half rings together to form a complete ring, thus at one movement circulation is arrested, and the artery is firmly held by the instrument and encircled by the ring

When the main locking-ratchet is released, the circular spring of the ring-anastomosis clamp brings the two halves of the double instrument together, approximating the two anastomosis rings As these rings come together, self-locking arms secure the half rings so that they will not open when the artery clamps are removed After removal of the clamps there is left in situ a comparatively small instrument, which may be rotated even within a small operation field to facilitate the suturing of the double flange of artery

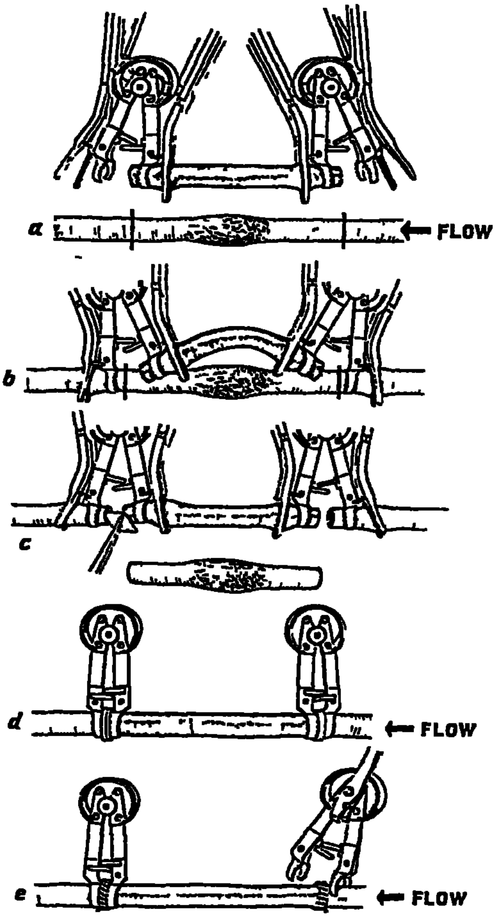

Fig 3—The replacement of a segment of diseased artery by a graft artery using the ice-cone method The time-interval between a and d is about 60 seconds

Fig 3 shows how the instrument may be put to practical use for the replacement of a portion of artery by a homograft Fig 3a shows a graft of suitable length, with a ring-clamp device attached to each end, laid alongside the diseased artery The outer half of each anastomosis device is now placed in position on the host artery, above and below the defect Simultaneous closure of both artery-clamps shuts off the circulation, locks the devices to the artery, and encircles the artery with the rings (fig 3b) The diseased segment is freed by division of the artery about 1 cm inside the outermost anastomosis rings Each device now holds a cut end of host artery and an end of the replacement graft in position ready for anastomosis (fig 3c) Immediately after insertion of the ice cones and closure of the two anastomosis clamps the artery clamps are released, so that flow may restart as soon as the ice melts The artery-clamps are disengaged and removed, leaving the two ring clamps in position (fig 3d) Suturing is completed while flow continues, and finally the ring clamps are opened and removed completely (fig 3e)

Experimental Results

This method has been tried both on human cadavers and on living animals Only common carotid or arteries of similar calibre have been used so far

Identical arteries—The instrument worked unerringly in the anastomosis of healthy vessels of similar calibre

Arteries from different subjects—The instrument had considerable latitude with regard to differences in calibre and texture of the arteries being anastomosed It never failed to anastomose two healthy arteries of the same anatomical name or of even approximately similar size Of fifty specimens, five common carotid arteries were found to be too small for the ring size designed for this vessel but were readily anastomosed by use of a slightly smaller ring

Atheromatous arteries.—Slight atheromatous thickening made little difference, though an inelastic thickened artery might tend to force a supple opposing artery to form a cuff on itself This did not, however, prevent the method from working The more severely atheromatous artery on occasions proved too unyielding for the instrument, and undue force tended to split the artery This could be remedied by making three slits in the inelastic intimal layer, so that the artery flanged readily as the three slits opened out Thorough removal of obliterating material in the partially or completely occluded artery left a supple vessel, well suited for the method We conclude that the device will handle without difficulty a properly disobliterated artery

Plastic arterial protheses—Orlon-cloth and polyvinyl-sponge tubes were well accepted

Relatively inaccessible arteries, such as the internal iliacs, were anastomosed more easily with the device than with conventional methods

Veins—The method has not yet been extensively applied to veins Limited experiments indicate that it is fully applicable though the serrations on the ring clamp may have to be modified

Experiments were done on the canine thoracic aorta because in size it matches the human carotid artery and because any undue delay in opening the circulation will be evident by renal failure or by spinal-cord damage In four dogs, 3 in lengths of homografts or heterografts were inserted into the descending thoracic aorta, this was accomplished with occlusion of flow for less than 7 minutes in each case The early version of the device was used for these experiments These animals recovered without difficulty and remain well after several months

In two dogs the latest version of clamp (fig 3) was used to insert 2 in lengths of grafts into the descending thoracic aorta This improved version proved successful, and circulation was restored within 4 minutes of the first occlusion Unfortunately a defect in the respirator caused the death of one dog while the chest was being closed The other dog remains well after several months In a third, an unusually large thoracic aorta was successfully "grafted" by use of suitably large ring clamps, this took 6 minutes, since each end of the replacement graft was anastomosed separately (not simultaneously) because of poor access through a small incision This animal remains well

Case-report

As these experiments were encouraging, we decided to try the method clinically

The patient selected suffered from severe claudication in both calves, due to bilateral block in the superficial femoral arteries At operation a homograft was inserted between the commencements of the superficial femoral arteries and the mid popliteal arteries, thrombendarterectomy was necessary for the upper part of each superficial femoral artery As the available grafts were not long enough, two homografts were anastomosed together for each side All the various anastomoses were end-to-end, and with the exception of the right upper anastomosis all were performed by the ice-cone method The circulation on each side was reopened within a few minutes and maintained through the ring clamps while suturing was completed On removal of the ring clamps there was negligible leakage through the suture lines and all anastomoses appeared to be of high standard An excellent pulsatile blood-flow to both feet has persisted over the two months since this operation

The method thus proved satisfactory on the moderately thickened arteries commonly encountered in this class of patient, and it avoided stagnation of the circulation from prolonged occlusion of the main femoral artery

Though the use of a soluble obturator in arterial anastomosis is not a new conception, our ice cone has, we believe, considerable advantages over the dextrose rod recommended by Smith (1945)

Summary and Conclusions

A method of arterial anastomosis, designed to allow nearly immediate restoration of blood-flow, is described It depends on the use of an ice shape and ring anastomosis clamps, it has proved very successful in dogs and has also given satisfaction in the one case of arterial *replacement* in man in which it has been tried By this method a portion of artery may be replaced by a graft with only brief interruption of the blood-flow

Though the method has not yet been tried sufficiently for us to recommend its use, except tentatively, in man, it appears promising It may offer a practicable means of anastomosing small vessels as well as large ones

The instrument is made by Messrs Thackray, 10, Park Street, Leeds, who will supply it for experimental purposes, but we wish to emphasise that the method can not yet be generally recommended for use in man The instrument incorporates important suggestions by Mr A B Hallam, of Messrs Thackray, who personally made the prototypes We wish to thank him and Messrs Thackray for their most valuable assistance in its development

We are indebted to Mr D P Hammersley for the illustrations

BLOOD TRANSFUSION SERVICE

PLASTIC bags for storing and transfusing blood were first introduced at Harvard Medical School in the late 1940s to facilitate research projects in the fractionation of blood The technique has since been developed commercially (Walter and Murphy 1952), largely as a result of the stimulus of the Korean campaign, and plastic equipment is now extensively used in the United States of America The present investigation was undertaken to test the suitability of one type of this equipment under conditions in this country and to ascertain if the published reports on the superiority over glass equipment could be substantiated

Source of Materials and Methods

The plastic bags were the 'Fenwal' type manufactured by the firm of that name at Framingham, Mass, U S A Fenwal bags are of the so-called type-1 design—i e, the tube that leads from the donor is an integral part of the bag and remains attached to it once withdrawal of the blood has been completed In the Fenwal system this donor tube may be used as a source of blood for cross-matching—i e, it forms an "integral" pilot tube Transfusions of blood from plastic bags were made with Fenwal giving sets, which resemble closely in basic design the experimental set tested by the Medical Research Council (1957)

A study was made of the general suitability of the plastic equipment as regards handling, filling, storing, mixing, and delivering

In six healthy young adult males the survival of the individual's own erythrocytes on reinjection into his own circulation was compared after storage in glass and in plastic

In three of the subjects blood was stored first in plastic and then in glass and the order was reversed in the other three

The same anticoagulant, in the same proportion relative to the blood withdrawn, was used in the plastic and in the glass containers This anticoagulant was prepared according to formula A of the U S P (dextrose 2 45 g , citric acid 0 8 g , trisodium citrate 2 2 g , water to 100 ml) 75 ml of this solution is contained in the plastic bag, and 60 ml was transferred directly from a bag to the glass bottles used for the trial In each case blood was stored for 28 days at the same constant temperature

The survival of red cells was measured with ^{51}Cr (Mollison 1956) The radioactivity in samples of blood was measured in a scintillation counter (Ekco Type N550) To estimate loss of labelled red cells from the subject's circulation between the time of injection and withdrawal of the first (10-min) sample of blood, the volume of red cells was estimated indirectly by the Evans-blue (T1824) technique of Crooke and Morris (1942) and from the dilution of ^{51}Cr-tagged cells in the circulation, the 10-min sample being used The red-cell volume measured by the dye technique was accepted as the " true " figure and used in each case to calculate the 100% value for the ^{51}Cr-tagged cells

TABLE I—WEIGHTS AND VOLUMES OF PLASTIC AND OF GLASS EQUIPMENT

Apparatus	Weight (g)
1 plastic bag with anticoagulant	113
4 plastic bags—airtight can	580
1 M R.C. bottle-waisted pattern with anticoagulant	590
	Volume (c.cm)
16 empty bags in airtight can	4014
4 glass bottles	6227
4 full bags (approximately)	3572

Hæmatocrits were corrected for trapped plasma and body venous hæmatocrit ratio (Chaplin and Mollison 1952, Mollison 1956)

Results

General suitability —The equipment was no more difficult to handle than conventional systems Weight-saving of a plastic bag over a bottle was very considerable, and volume-saving on full bags was slightly less than 50% (table I)

Filling—Ordinary gravity-filling was used The bags are designed to hold 500 ml of whole blood—more than is usually withdrawn in this country Unless some means of weighing the bag is used (equipment for this is, of course, available), it is difficult to tell when the flow should be stopped The time taken to collect 500 ml of blood varied from 6½ to 8 minutes, which compares favourably with the time required to fill a conventional glass bottle

Mixing —Blood stored in plastic bags proved as difficult to mix as that preserved in glass bottles Table II gives the packed-cell volumes of representative samples of blood drawn from plastic and glass containers after the gentle agitation usually undertaken before administration Blood from these containers, when fully mixed, had a packed-cell volume of about 40%

Delivery-rates —Table III summarises the results of delivery trials under different conditions The size of the tubing of the giving sets is of more importance than the container in determining the rate of flow of blood under gravity The performance of a plastic bag for pressure transfusion by hand is unsatisfactory compared with the standard equipment in use in this country, but again the difference is largely a result of the dimensions of the giving set Squeezing a plastic bag is effective but tiring, and this experience is in accord with that of J M Howard in Korea (personal communication)

TABLE II—PACKED-CELL VOLUME OF STORED BLOOD AFTER MIXING BY GENTLE AGITATION

Subject no	Method of storage	
	Plastic	Glass
1	33·0	27·0
2	27·0	49·5
3		13·0
4	15·5	74·0
5	29·0	
6	29·0	45·0

TABLE III—RATES OF FLOW

—	Flow (ml per min)
Free gravity flow (135 cm head, means of 4 experiments)	
Plastic bag—plastic giving set (residual blood in bag =30 ml)	56
Same—with prefiltered blood (no residual)	66
Standard bottle—giving set—standard glass-rubber set (filter in bottle)	81
Standard bottle—plastic giving set	69
Pressure infusions	
2-handed pressure on plastic bag	155
Standard bottle and glass-rubber set—sphygmomanometer bulb	394
Standard bottle—plastic giving set and sphygmomanometer bulb	116

All experiments used the National Blood Transfusion needle

Multiple transfusions out of plastic bags through the same giving set did not prove satisfactory In one such case less than half the rate achieved with the first bag under conditions of force flow proved possible with the second

Red-cell survival —Table IV lists the 24-hour figures for red-cell survival 24 hours after transfusion When a sample was not drawn at exactly 24 hours, this figure was derived from the survival curve The survival of erythrocytes after storage showed considerable variation from one individual to another, as had previously been reported by Mollison (1956) for glass containers Nevertheless there was a close similarity between the survival of erythrocytes in the same individual when reinjected into his own circulation, whether they were stored in plastic or in glass, and it was clear that improvement in red-cell survival is not brought about by storage in plastic containers under the conditions of this test

Discussion

The advantages claimed for plastic bags are less weight and a smaller volume for storage, freedom from air embolus in pressure transfusion, integral pilot tube, disposability, and better preservation of blood

TABLE IV—PERCENTAGE SURVIVAL 24 HOURS AFTER TRANSFUSION OF RED CELLS STORED BY DIFFERENT METHODS

Subject no	Method of storage	
	Plastic	Glass
1	64·0	62·0
2	57·0	60·0
3	81·5	87·0
4	84·0	87·0
5	57·0	61·0
6	66·0	78·0

Weight advantages for both empty and full bags are obvious, but it should be noted that the saving of space is nothing like so great as that of weight Pressure transfusion is certainly free from air embolus but, unless special equipment for compressing the bag is available, it is slower than the conventional bottle methods The integral pilot tube could be a real advantage, particularly to those who object to opening bottles for matching blood (Campbell 1956) Except under the conditions of war, the advantages of disposability will rest on cost, and at present the cost of plastic transfusion equipment is probably nearly twice that of conventional apparatus

It has been suggested that the overall design of the set (laminar flow hæmorepellent surfaces, and the absence of glass) favours the preservation of all the elements of the blood and in particular prolongs the storage life of the red cells The clinical evidence for the first statement is scanty, and that for the second is based on three experiments by Strumia (1955) and by Strumia et al (1955), in which blood stored for 21 days showed better survival if stored in plastic than if stored in glass These results were obtained from two autotransfusions and one transfusion with a compatible recipient and do not give a satisfactory estimate of the difference between plastic bags and glass bottles Gibson's (1956) figure of 10% superiority of survival of red cells stored in plastic compared with glass is also based on an unknown number of experiments, Wall et al (1953) found that red cells survived in vitro less well when stored in plastic than when stored in glass

Walter et al (1957) have obtained 28-day survivals that correspond closely to those reported here and have claimed enhanced survival However, without direct comparison between plastic and glass storage such a claim is difficult to substantiate, and the results of the present investigation suggest that, for all practical purposes, at the end of 28 days red cells stored in glass survive as well and are as satisfactory for expansion of red-cell volume as those stored in plastic

Summary

A plastic bag for storing and transfusing blood was subjected to clinical trial

Its performance for routine purposes was in no respect superior to that of the conventional system, but its routine use would confer minor advantages such as freedom from the danger of air embolus

The post-transfusion survival of red cells was not improved by storage in plastic bags

We wish to thank the blood-transfusion research committee of the Medical Research Council for advice on planning the trial, and Prof John Bruce for support and advice

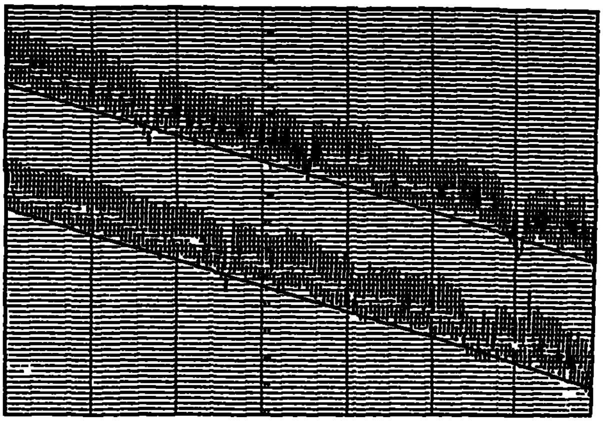
BASAL METABOLIC RATE IN OLD MEN

AND RELATED DATA

J Douglas Robertson
M D , D Sc St And , F R.C P , D P H
CONSULTANT CHEMICAL PATHOLOGIST, THE WEST LONDON HOSPITAL, LONDON, W 6

There are very few records of the basal metabolic rate (B M R) of healthy men over the age of 90 years in fact I have traced only two Benedict and Root (1934) and Benedict (1935) studied one subject aged 91, and Kise (1932) studied a Japanese aged 93 As Benedict (1935) put it " The difficulties in studying the metabolism of normal people of advanced age can hardly be overestimated Complete co-operation from the subject is necessary and a hospital environment is prohibited—both features that contribute to increase the difficulties of securing suitable subjects " For that reason, Benedict said, no further study of elderly men by the Nutrition Laboratory was planned Aub and Du Bois (1917) could find no suitable subjects between 90 and 100 years old



Basal metabolism chart of the centenarian (subject E)

I have studied five normal, healthy men aged between 90 and 100 All were living at their homes, were ambulant, were leading perfectly normal lives, and were not under any form of medical treatment For example, one was paying regular visits to his several clubs in London, one was speaking at city dinners, and the other three took regular exercise by daily walks All of them co-operated excellently during the investigations Three took transport to the metabolism department for the determination, and the other two were seen at their homes because they preferred to continue their custom of having breakfast in bed! The standard technique of measuring the B M R —as described by Robertson (1944)—was strictly adhered to The results are given in the table

In 1952 Robertson and Reid gave prediction tables for the expected mean heat-output in calories per square metre body surface per hour, and for men over 41 gave this formula 37 405365 minus 0 06944 × age in years For a person aged 95 (the mean of the series) this would give an expected mean of 30 8 calories per square metre body-surface per hour, compared with an observed value of 29 5

During the second metabolism reading, the pulse-rate of each subject was taken several times, after he had been at rest for at least forty minutes, and the lowest rate was recorded The blood-pressure was taken after each subject had been at rest for at least fifty minutes and after the metabolism readings were completed

Subject	Age	Height	Weight	Basal pulse-rate	Basal blood-pressure	Respiration-rate	Heat production (calories per 24 hr)			Heat production (calories per sq m body surface per hr)
							Total	per kg	per sq metre	
	(yr)	(cm)	(kg)	(per min)	(mm Hg)	(per min)				
A	91	165	54 3	62	125 75	8	1073	19 7	673	29 1
B	93	154	42 7	70	230 105	20	1055	24 7	765	31 8
C	95	168	56 3	60	160 95	14	1166	20 7	715	29 8
D	97	168	59 5	52	200 105	17	1120	18 8	666	27 7
E	100	160	67 3	62	190 105	21	1220	18 1	718	29·9
Mean	95	163	56 0	61	181 96	16	1127	21 1	705	29 5

Data on standard or basal blood pressure and pulse rate, as presently described, will be reported later on the Robertson and Reid B.M.R. standards (1952) which range from the ages of three to seventy-five years.

SICKLE-CELL TRAIT IN CENTRAL INDIA

R. N. Shukla

B. R. Solanki

From the Department of Pathology and Bacteriology, Medical College, Nagpur, India

The incidence of the sickle-cell trait in non-Negroid ethnic groups of different parts of the world appears to be higher than was thought. The trait has been found in countries bordering the Mediterranean as well as in parts of the Middle East (Lehmann 1954).

In India the sickle-cell trait has been noted in various regions. Lehmann and Cutbush (1952) reported, and Buchi (1953) confirmed, its presence in the Veddoids of South India. Sukumaran et al. (1956) found it in tribes of Western India, and Foy et al. (1956) in certain tribes of Eastern and Southern India. Stray cases have been reported from Assam (Dunlop and Mozumdar 1952) and Uttar Pradesh (Bhatia et al. 1955).

Having come across several cases of sickle-cell disease, in quick succession, in Nagpur and surrounding areas, we tried to find out the local incidence of the trait.

Materials and Methods

As a first step, a survey was made among the adult labourers of the Model Mills, Nagpur. The people examined were selected at random, except that an effort was made to ensure that no two of them belonged to the same family. The labouring population hails from different districts within a hundred miles of Nagpur. In all, 1010 persons were examined.

The presence of sickling was demonstrated by the method of Daland and Castle (1949). Fresh reducing solutions were made daily, and preparations were examined within two hours. All positive cases found on one day were re-examined the next day to eliminate false positives. Dried and stained smears of peripheral blood were examined in all cases for morphological abnormalities of red cells and for target cells. In cases showing target cells in dried smears and sickling in a wet sealed preparation, hæmoglobin analysis was done by paper electrophoresis and by alkali denaturation for confirmation.

The results of the survey are given in the table.

Most of the 1010 persons examined belonged to the local Marathi-speaking population. Sickling was present in Mahars, Kunbis, and Telis. The other groups—Gond, Koshti, Brahmins, Mohammedans, and miscellaneous groups including various other castes—did not show sickling. In Mahars the incidence of sickling was 22·2% and in Kunbis and Telis 9·4% and 11·3% respectively. Paper-electrophoretic studies in positive sickling cases showed the AS pattern, confirming the presence of sickle-cell hæmoglobin in the heterozygous form.

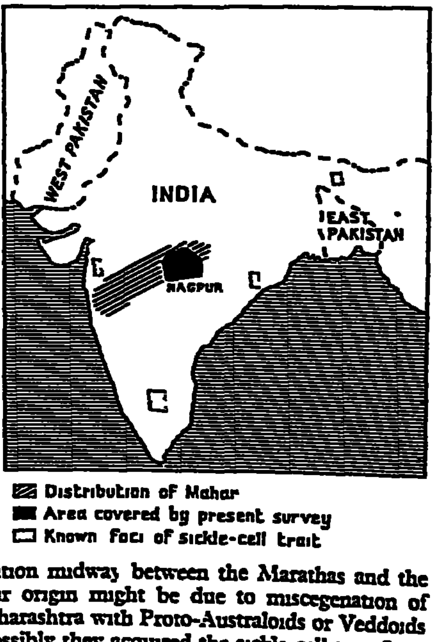
INCIDENCE OF SICKLE-CELL TRAIT IN CENTRAL INDIA

Caste	No. of persons examined	No. of persons positive for sickling	Incidence of sickle-cell gene
Mahar	450	100 (*22·2%*)	0·12%
Kunbi	116	11 (*9·4%*)	0·05%
Teli	80	9 (*11·3%*)	0·06%
Koshti	46	0	
Gond	53	0	
Mohammedan	68	0	
Brahmin	26	0	
Miscellaneous	171	0	
Total	1010		

Discussion

The high percentage of the sickle-cell trait in certain tribes of India is of interest. It is generally agreed that the sickle-cell trait was not brought to these tribes by Negro-immigration. On the presence of the Negro race in India in prehistoric times conflicting views are held. Judging from the tribal population of the present day there is no weighty evidence in support of a Negro admixture. Most anthropologists agree that the earliest inhabitants of India were Proto-Australoids. There is evidence that, in the Western coastal region, some infiltration of an African element took place during the 8th to 10th century A.D. (Mozumdar 1944). But these involved only local mixing. They were Mohammedans, and it is not yet established what kind of Africans they were. For instance, if they were Somalis they would have been unlikely to have carried the sickling gene (Lehmann 1954). Had there been a generalised assimilation of a Negro immigrant population in India, characteristic features would be met with more often in all parts of the country. The presence of the sickle-cell trait in various regions of India therefore cannot be due to mixture with Negroid blood.

The Mahars, in whom we have demonstrated the sickle-cell trait, are widely spread in Maharashtra (see figure) and speak Marathi. They are included in the scheduled castes and are hereditary village servants doing menial work. Owing to modern industrialisation they are now concentrated mostly in the cities and are employed in textile mills and other industries. On the basis of anthropometric measurements they appear to be a mixed community occupying a position midway between the Marathas and the primitives. Their origin might be due to miscegenation of primitives of Maharashtra with Proto-Australoids or Veddoids of the South. Possibly they acquired the sickle-cell trait from the Veddoids in prehistoric times. The habits and customs of Mahars do not preclude the possibility of such infiltration of Veddoid blood.



WEST PAKISTAN
INDIA
EAST PAKISTAN
NAGPUR
▨ Distribution of Mahar
■ Area covered by present survey
☐ Known foci of sickle-cell trait

The Kunbis and Telis are different castes of Marathas. The caste status depends mainly upon the occupation followed. Kunbis are mainly agriculturists, and Telis are oil-pressers. According to Karvey and Dandekar (1951) both belong to mesocephalic elements which came to India from the North-

West and settled in the broad fertile valleys of Central Maharashtra Anthropologically they are totally unrelated to the dolichocephalic Veddoid or Proto-Australoid primitives of South India

The presence of the sickling trait in these castes is thus of great interest and raises important questions as to the method by which they acquired it Normally social customs are such that they could not have got it from Mahars, and their origin from the Northern immigrants shows that the trait is not derived from their main ancestors An independent mutation can always arise, but otherwise the only possibility left is that Veddoid blood may have found its way into these people in the same manner as to the Mahars, or, in South India, to the Todas and Badagas A similar explanation of the presence of the sickle-cell trait in Mediterranean people is suggested by *Lehmann (1953)* Extensive anthropological studies about the presence of any Veddoid features in these people will be of great interest It is now clear that the sickle-cell gene protects in some degree against the more severe effects of falciparum malaria If the gene was introduced into an endogamous community by even a few individuals the gene frequency could have risen with every succeeding generation as the result of a slightly higher malarial mortality of the non-sicklers

Summary

At Nagpur 1010 adult labourers of different castes were examined for the sickle-cell trait

In the Mahars, Kunbis, and Telis its incidence ranged from 9 4% to 22 2%

It is highly improbable that this trait was brought to India by Negroes from Africa More probably the present population acquired it from the primitive Veddoids or Proto-Australoids

We wish to thank the management of Model Mills, Nagpur, for permitting us to undertake this study, and we are indebted to Shri B A Sathe, labour welfare officer, Model Mills, and to Dr J Sood and Shri D N Hakim, without whose help it would have been impossible to complete the study for technical help, our thanks are due to Shri V G Jog Prof J B Shrivastav, of the Medical College, Nagpur, and Dr P M Bhandarkar, the dean, have authorised publication of this report The survey was conducted with a grant-in-aid from the Indian Council of Medical Research

Preliminary Communication

INTRARENAL VARIATIONS IN HÆMATOCRIT

The whole-body hæmatocrit is lower than that of the blood in large vessels, and the hæmatocrit in the kidney has been found to be only a third to a half of that in the large veins [1] [2] Fahræus [3] showed that, because of axial streaming of corpuscles, blood flowing through smaller tubes contains a higher proportion of plasma This "streamlining" effect on small-vessel hæmatocrit has been regarded by Pappenheimer and Kinter [4] as not adequate to explain fully the low hæmatocrit observed in the kidney, and they have suggested that the series of glomerular afferent vessels coming off the interlobular arteries constitutes an apparatus for drawing off the cell-poor peripheral layer of blood—a "plasma-stripping" effect, in consequence of which the juxtamedullary glomeruli would receive blood of low hæmatocrit, while the outer glomeruli would receive blood of progressively higher hæmatocrit Since the blood supplied to juxtamedullary glomeruli pursues a later course separate from the cortical circulation,[5] it appeared of interest to see whether the hæmatocrit differs substantially in different zones of the kidney If streamlining were the predominant mechanism, the hæmatocrit would be low in zones containing many small vessels, whereas Pappenheimer's plasma-stripping effect would allow of the occurrence in quite large vessels of blood of low hæmatocrit, determined by its site of origin in the juxtamedullary glomeruli

INVESTIGATION

Methods

After exposure and gentle freeing of the kidneys and renal pedicles under pentobarbitone anæsthesia, dogs were given intravenously a suspension of their own erythrocytes, previously labelled with ^{32}P, in saline containing ^{131}I-labelled human plasma-albumin After ten minutes to allow adequate distribution of the injected cells and albumin, a blood sample was taken, the renal artery and vein were simultaneously ligated and divided, and the excised kidneys were frozen in a CO_2-ethanol mixture The renal pelvis was then cut away to expose the tip of a papilla, and a core of kidney from papilla to cortex was removed in a cork-borer The frozen core was extruded by a screw, and serial sections 1–2 mm thick were placed on plastic discs and weighed The amount of ^{32}P and ^{131}I in each slice was calculated after appropriate radioactivity measurements, and the relative amounts of ^{32}P and ^{131}I in the sample of venous blood were also determined From these results was calculated for each slice the hæmatocrit percentage $^{32}P/(^{32}P+^{131}I)$, and the "vascular volume" (sum of the spaces occupied by cells and plasma)

Results

Our findings will be reported in detail elsewhere, but the general pattern is shown in the figure, which represents the mean results obtained from 13 kidneys treated in this way (single kidneys with thin slices from 5 dogs, both kidneys with thicker slices from 4 dogs) The hæmatocrit in each zone has been expressed as a percentage of the large-vessel hæmatocrit of the dog from which the kidney was taken The inner zone of cortex contained blood whose hæmatocrit was significantly higher than that in the outer zone of cortex ($P<0\ 01$), and the blood in the cortex (both zones) was of higher hæmatocrit than blood in the medulla ($P<0\ 001$) For the series of 13 kidneys, the corticomedullary hæmatocrit difference was positively correlated with the difference in hæmatocrit between inner and outer cortex The differences in hæmatocrit were not related to variation in "vascular volume" or to the presence of visible large vessels

DISCUSSION

The observation that the hæmatocrit is lower in the outer cortex than in the inner cortex can probably be explained by the preponderance in the outer cortex of small vessels, in which streamlining alone would lead to a low hæmatocrit. Our observations on the distribution of hæmatocrit within the cortex clearly give no support to the view that because of plasma-stripping the more superficial glomeruli receive blood of high hæmatocrit, but equally they do not exclude this possibility, since the technique used cannot differentiate between the small amount of blood in the glomeruli and the much larger amount in the peritubular capillaries

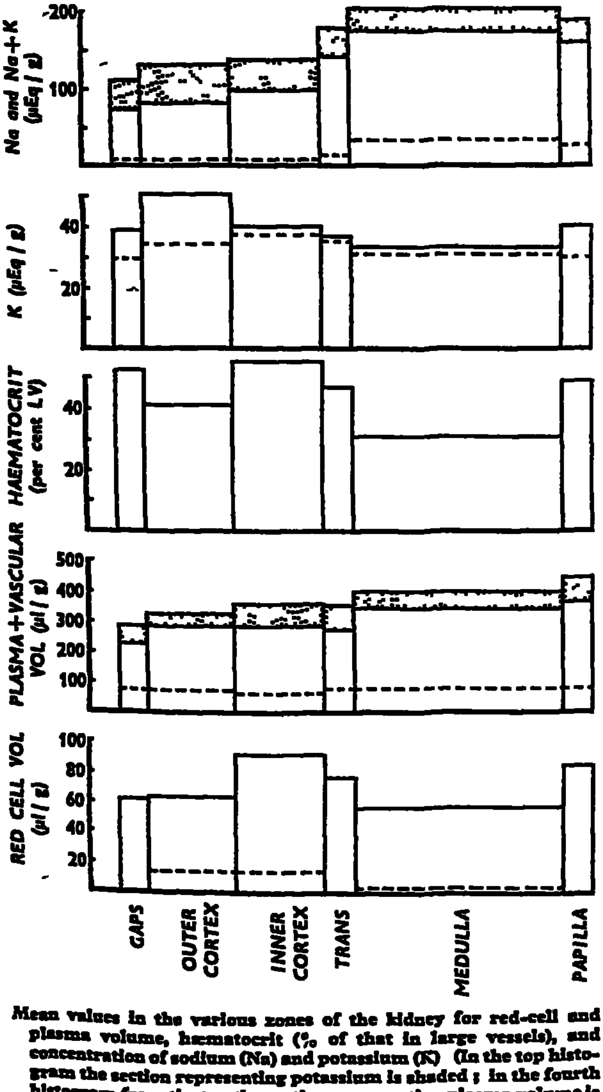
2 Allen, T H, Reeve, E B *Amer J Physiol* 1953, 175, 218
3 Fahræus, R *Physiol Rev* 1929 9 241
4 Pappenheimer, J R, Kinter, W B *Amer J Physiol* 1956 185, 377
5 Trueta, J, Barclay, A E, Daniel P M, Franklin, K J, Prichard, M M L Studies of the Renal Circulation. Oxford, 1947

Our finding of a low hæmatocrit in the medulla seems to us much more conclusive evidence that streamlining effects must be supplemented by plasma-stripping effects, as suggested by Pappenheimer The vasa recta of the medulla are large vessels, and so might be expected to contain blood of a relatively high hæmatocrit, our finding that the hæmatocrit in this zone is in fact the lowest in the kidney suggests that these vessels have been supplied with blood which was of low hæmatocrit right at its source from the interlobular arteries We think that this finding supports Pappenheimer's view that blood of low hæmatocrit is drawn off into the juxtamedullary glomeruli, from which the vasa recta are supplied

Since red cells perfuse the kidney more rapidly than plasma, and since the renal-vein hæmatocrit is similar to the renal-artery hæmatocrit, the existence of a (predominantly) plasma shunt must imply the existence elsewhere of a (predominantly) red-cell shunt This might be no more than the fast axial stream in a multitude of small vessels, or it might be a smaller number of large communications such as permit the passage of glass beads of up to 180μ diameter[7] Our results cannot discriminate sufficiently between these alternatives, but the finding of a higher hæmatocrit in the inner than in the outer cortex might suggest that the inner zone of cortex contains high-hæmatocrit arteriovenous shunts There is a possible anatomical basis for this view in the large vessels of the "arcuate sponges" in this region[8]



Mean values in the various zones of the kidney for red-cell and plasma volume, hæmatocrit (% of that in large vessels), and concentration of sodium (Na) and potassium (K) (In the top histogram the section representing potassium is shaded ; in the fourth histogram from the top the section representing plasma volume is unshaded.) The distribution of hæmatocrit is discussed in the text ; the high concentration of (Na+K) in the medulla confirms the findings of Ullrich and Jarausch.[6]

The broken line across the histograms for Na, K, plasma, and red-cell volume indicates the amounts remaining in a kidney which had been perfused at a pulsatile pressure of 130/80 mm Hg for ten minutes with salt-free 6% dextran In the various zones of this kidney, differences in "apparent extravascular albumin" were insufficient to account for the differences in apparent hæmatocrit found in the series of other kidneys

Caps.=capsule. Trans =transitional zone

Our main finding, however, is that the medulla contains low-hæmatocrit blood, though from the large size of its vessels blood of high hæmatocrit might have been expected This finding is most easily explained on Pappenheimer's hypothesis that low-hæmatocrit blood is "stripped off" into the proximal branches of the interlobular arteries to supply the juxtamedullary glomeruli (and hence the vasa recta of the medulla)

Reviews of Books

Burns Pathology and Therapeutic Applications

Simon Sevitt, M D , M SC., F R.C.P I , consultant pathologist to the Birmingham Accident Hospital and M R.C. Burns Research Unit. London Butterworth 1957 Pp 364 37s 6d

Burns may kill in various ways and postmortem examination often shows little macroscopic evidence of the immediate cause of death, apart from the local lesion Peripheral circulatory failure, electrolyte disturbance, damage to kidneys, lungs, brain, or other tissues, ill-advised fluid replacement, toxic absorption of local applications, bacterial infection these and many other factors may be involved During the past twenty years much has been learned about these matters and many detailed studies are scattered through the world's literature Dr Sevitt is to be congratulated on collecting and collating this mass of information and condensing it into a book of readable size He has had wide experience as pathologist to the M.R C Burns Research Unit in Birmingham, and the addition of his own observations and experimental work make this a book of exceptional merit for the first time in English a detailed discussion of all branches of the pathology of burns appears in a single volume The book is divided into three sections the local pathology of the skin, the mortality and causes of death, and the pathology of various systems and organs There are also additional chapters on burns from other causes, including irradiation

Many more patients with extensive burns now survive the shock phase only to die during the subsequent weeks, and it is during this period that the mortality-rate can still be reduced The first requisite is a thorough knowledge of the complex changes in function which follow burning, and Dr Sevitt's book presents the available information clearly and concisely It should be widely read by all those who have to deal with these perplexing cases

The Clinical Application of Hormone Assay

JOHN A. LORAINE, M B, PH D, M R C P E, member of scientific staff, clinical endocrinology research unit (Medical Research Council), University of Edinburgh Edinburgh and London E & S Livingstone 1957 Pp 368 30s

THIS book has three purposes to review existing methods of hormone assay, to discuss their clinical application, and to suggest lines for future application The result, however, is largely a discussion on methodology for the assay of pituitary, placental, adrenal, and gonadal hormones, with a brief chapter on insulin The thyroid and parathyroid hormones are not considered

The chapters on general principles in hormone assay and on pituitary gonadotrophins are particularly valuable, reflecting as they do the careful work of the Edinburgh group The clearly written introductions to the other chapters are also helpful Much space is devoted, however, to methods no longer in use and now only of historical interest The present trend is to progress from bioassay to chemical methods and from relatively non-specific to more specific chemical procedures In the corticosteroid chapter, for example, the cold-protection and mouse eosinophil tests could have been omitted, and methods for determining reducing or formaldehydogenic steroids curtailed to give space for a more critical discussion of the methods of Norymberski

Compared with methodology, much less space is devoted to clinical application In part this is due to the inevitable delay in collecting results obtained with the newer and more reliable methods (as Dr Loraine emphasises, their future application to clinical problems will be awaited with interest), but it is also partly the result of leaving out a good deal of published data which the clinical reader might expect to find in a book of this title

The Truth about Cancer

CHARLES S CAMERON, M.D London Hutchinson Medical Publications 1957 Pp 256 30s

Cancer and Common Sense

GEORGE CRILE, Jr, M.D London Robert Hale. 1957 Pp 143 10s 6d

THE book by Dr Cameron, who is medical director of the American Cancer Society, was written for the laymen of that country, and its style will be less familiar to British readers There is a great amount of technical detail (the index lists almost a thousand topics) and some of the headings (retinoblastoma, acid phosphatase, and xeroderma, for example) seem a little incongruous in a "popular" book But it is very lucidly written, and its object is clear enough—the patient must be warned of the significance of certain "danger signals" and encouraged to act on them
